v. 11

1877

AN

ILLUSTRATED WEEKLY JOURNAL

OF

HORTICULTURE IN ALL ITS BRANCHES.

FOUNDED BY

W. Robinson, F.L.S., Author of "Alpine Flowers," etc.

"You see, sweet maid, we marry
A gentle scion to the wildest stock;
And make conceive a bark of baser kind

By bud of nobler race: This is an art
Which does mend nature; change it rather; but
The art itself is nature."—*Shakespeare.*

VOL. XI.

LONDON:

OFFICE: 37, SOUTHAMPTON STREET, COVENT GARDEN, W.C.

MIDSUMMER, 1877.

THE GARDEN.

VOL. XI.

FLOWER FORCING AT BEXLEY HEATH.

LET the season of the year be what it may, our florists' shops teem with flowers of the choicest descriptions. Even during the worst weather, when scarcely a flower of any note can be found in ordinary gardens, we here find them exposed for sale in great quantities, and people who are unacquainted with our large suburban plant-growing establishments, may well be astonished that such plentiful supplies can be so regularly produced and disposed of. A visit to any of our market-supplying nurseries—Ladds', for instance, at Bexley Heath—however, clears up the mystery. In Mr. Ladds' place there is, perhaps, more glass than in any other establishment in which plants and flowers are grown wholly for market, and, considering the bleakness of the situation in which it is placed, the wonder is how early flowers can be grown to such perfection and in such large quantities as we here find them. At this, as at every other place of the kind, certain races of plants are made a speciality. The principal kinds grown here are Roses, Zonal Pelargoniums, and Gardenias, and these chiefly for supplying flowers in a cut state. To Tea Roses three span-roofed houses, each 300 ft. long and 30 ft. wide, are devoted. The plants, which are grown in pots are trained in the form of pyramids by placing a strong stake in the centre of each pot, to which the main stem is fastened. The varieties grown consist of Niphotos (white) and Isabella Sprunt (yellow), the aim being to grow only such sorts as will produce a profusion of finely-shaped buds for several months in succession, and these two kinds are found to do that better than any others. In August the plants are brought from outdoors and placed in the houses, where their shoots receive a little regulating and tying, and where they are kept in a cool, airy atmosphere until they show flower, when a little heat is applied in order to bring them forward. They are then subjected to a brisk heat and to abundance of moisture both as regards tops and roots, and from the middle of September until the end of May they yield a supply of bloom varying from 70 to 200 dozen per day. Hybrid Perpetuals are not grown on such an extensive scale as Teas; nevertheless, one house, of the dimensions just mentioned, is entirely devoted to them in winter and spring. The plants, which are standards, are planted out in a prepared bed, which runs down the middle of the house, the tallest being in the centre. These

usually bloom from February to April, after which Roses do not pay to have a house wholly devoted to them. They are therefore taken carefully up and planted out-of-doors in good ground until they are again required for forcing. Sometimes they suffer by being thus suddenly turned out of a warm house into the open air even in April, but having the whole of the summer to recruit themselves, they invariably give satisfaction. These are, as a matter of course, pruned in the autumn in the ordinary way, and are placed in their winter quarters as soon as convenient, care being taken not to excite growth until the flower-buds are formed. It is worthy of remark that not a trace of mildew, green fly, or other pests with which Roses are troubled is here to be found; on the contrary, the foliage is fresh looking, clean, and healthy, a result brought about by timely attention to fumigating, sulphuring, watering, and syringing several times a day. Mr. Ladds indeed, believing that prevention is better than cure, sulphurs the hot-water pipes in his Rose houses occasionally, whether there are signs of mildew or not. The largest of the buds are gathered every evening, and a piece of matting is tied round each of them in order to prevent the petals from falling before they reach their destination. They are then packed in boxes and sent to market early next morning. Among Hybrid Perpetuals Gen. Jacqueminot and Victor Verdier are the kinds found to answer best. The houses from which the Roses have been removed are filled during the summer months with bedding plants, such as Pelargoniums, Calceolarias, and Fuchsias, all of which are grown by tens of thousands and sold to the trade. One house of Tea Roses is, however, retained for supplying bloom in summer.

GARDENIAS.—Like Roses, these are grown here on an extensive scale, a house 200 ft. long and 30 ft. wide being entirely devoted to their culture. They are permanently planted out on mounds a foot or so higher than the floor of the house, with the view of preventing the plants from becoming sodden at the roots through the continual heavy syringings to which the foliage is necessarily subjected in order to keep it free from insects and in a healthy state. Some of the plants are 6 ft. to 7 ft. in height and nearly as much in width, and they are just starting into growth and showing their flower-buds. Previously to commencing to force, the plants receive a thorough dusting with a mixture of soot and guano, in order to clear

them of mealy bug, a pest to which they are subject. In that state they are allowed to remain for some days, when the mixture is washed off the foliage by means of a powerful syringe. This treatment, Mr. Ladds asserts, eradicates all insects, and, owing to forcible and frequent syringings, they never again gain a footing until after the blooms have begun to open, when syringings must necessarily be discontinued; if they then show themselves, they must be afterwards cleared off when the plants go out of bloom. The guano and soot when washed off stimulate the roots and serve to induce a free and healthy growth; and, although sometimes the foliage is slightly burnt by the mixture, yet this does not apparently injure the constitution of the plants, for they look wonderfully healthy and yearly yield hundreds of thousands of large, pure white, deliciously-scented blossoms.

ZONAL PELARGONIUMS as grown here serve two purposes; they supply cut blooms during winter and furnish compact, well-flowered plants with which to decorate the window sills and balconies of the London streets during summer. Vesuvius and Master Christine are the only kinds grown, with the exception of a few white-flowered sorts upon which no great value is set. Three span-roofed houses, 200 ft. long, furnished with 8 ft. beds on each side of the centre path, are devoted to Vesuvius; and Master Christine occupies a house of similar dimensions. These, notwithstanding the large quantities of blooms that are daily gathered from them, are still dense masses of scarlet and pink. Cuttings of both these varieties are struck in June, potted into 5-in. pots when well rooted, and freely exposed to the sun until the end of September, when they are placed in the houses in which they are to flower, each plant being set on an inverted flower-pot sufficiently distant from its neighbour to allow the air to circulate freely amongst them, thereby preventing the foliage and flowers from damping off in wet weather. The plants are potted in good loam, all kinds of manure or leaf-mould being avoided, as these only promote rank growth at the expense of bloom. The great point is to get the wood hard and well ripened early in autumn, and in order to accomplish this, and keep the plants dwarf and compact, no more water is given than is absolutely necessary to keep them in a healthy condition. When placed in the houses, they are kept very dry at the roots, and a dry atmosphere is also maintained. Any plants that show a want of vigour, or bloom sparingly, are watered with liquid guano, which soon improves their condition. The flowers are picked regularly every evening and by the same person, who takes great care never to pluck a truss one day that would last in good condition until the next. As they are gathered they are placed in wooden trays carried by boys on their heads, and when full are taken into the packing-house to be gummed; this process is also performed by boys, who, with a finely-pointed stick, drop the smallest possible quantity of prepared liquid gum into the eye of each flower; this keeps the petals stiff, and prevents the flowers from falling to pieces. When gummed, they are tied in bunches and packed for market. When they cease to realize good prices, the plants are cut back and prepared for their summer duties. Camellias, Spireas, Lilies of the Valley, and many other plants are also grown extensively in this establishment. To the former several houses are devoted; *Jasminum grandiflorum* is also well grown here, as indeed are many other kinds of plants, but Roses, Gardenias, and Pelargoniums form the bulk of the stock. S.

FINELY BLOOMED PLANTS OF *HIPPASTERIA AULICUM*.—Specimens of this old-fashioned Amaryllid are now blooming profusely in Messrs. Veitch's nursery at Chelsea. Amaryllids when in flower are at all times showy, but when grown, as they may now be seen in the nursery in question with five or six large bulbs in a pot, each bulb being furnished with two or three strong flower-spikes 3 ft. in height, and bearing several fully expanded and gorgeously coloured blooms, they are especially striking.—S.

GARDENERS' BENEVOLENT INSTITUTION.—At the annual general meeting of this charity, which is to take place on the 18th inst., three pensioners are to be elected, and it is hoped that all who have the opportunity will vote for Mrs. Ayres (recommended by Mr. Newton, Mr. Wills, and others) in order that she may be placed on the pension list. She is the widow of the late Mr. W. P. Ayres, so long and so well known to all connected with horticulture.

NOTES OF THE WEEK.

HONESTY-PODS AS WINTER ORNAMENTS.—The pods of the Common Honesty (*Lunaria biennis*) are justly esteemed on account of their value for vases, &c. Their satiny hue by artificial light is charming, especially when seen before mirrors. One of the prettiest combinations is that of Feather Grass and Honesty. Only the inner division of the pod should be left, the outer ones, which are generally weather-worn and soiled, are easily rubbed off between the finger and thumb. Where the plant grows freely fine panicles of pods are formed, one of which, well preserved, suffices for a large vase. Small side bits are very pretty in little vases with or without the more delicate Grasses.

NOTES FOR THE "GARDEN."—The editor asks the aid of contributors, correspondents, and readers to contribute to the notes, questions, and paragraphs in THE GARDEN. From the first Number published it has always been part of the plan of THE GARDEN to make these a special feature, and as they have been found very useful to its readers, it is desired to make them as interesting as possible. This, however, is part of the work which can only be efficiently done by our readers and correspondents, for whose aid we shall be grateful.

PLANTS IN FLOWER IN DORSETSHIRE.—The weather here is unusually mild although extremely wet. Violets of all kinds are flowering in great abundance. I have been gathering the Neapolitan kind from the open borders all the winter, and have to-day (Jan. 1), gathered a good supply of them. The Glastonbury Thorn is also flowering freely; a large tree of it here has been opening its blossoms for the last fortnight. *Chimonanthus fragrans* has been in flower for some time, and is now in full bloom.—D. UPHILL, Moreton, Dorchester.

WINTER CROCUSES.—Your correspondent "B." in an article on winter flowers out-of-doors, in your impression for Dec. 9, mentions having seen *Crocus albiflorus* and *C. Fleischeri* in bloom. There must be some mistake here. Mr. Maw informs me that *C. albiflorus* does not appear above ground till March in its native habitat, the Carso of Trieste. The bulbs which Mr. Maw kindly gave me are now only just showing their green tips above ground in a pot which has been in the greenhouse for the last three months. *Crocus Fleischeri* does not bloom till the end of February or the beginning of March in this country, though its leaves have been for some time above ground. The Crocuses which your correspondent saw in bloom were, I have no doubt, varieties of *C. levigatus*—the description answering exactly to specimens which were in bloom here at the same time. The white anthers at once point to this species. It comes very near *C. Boryi*, which in its typical form is pure white with orange throat. The Crocus which best deserves the name of winter Crocus is, I think, *C. Imperati*. I have a small round bed of it now (January 1) in full bloom. If we could only get a still bright morning it would be one mass of delicate mauve stars. Through the kindness of a friend who resides near Naples I have received a few bulbs of the white variety of this beautiful Crocus. They are now showing above ground, but will not bloom till 1878. There is also a pure white variety of the handsome Crocus byzantinus. It is figured by Reichenbach in his "Icones," but does not yet appear to be in cultivation.—H. HARPUR CREWE, Drayton-Beauchamp Rectory, Tring.

OUTDOOR FLOWERS AT WORTHING.—The season here has continued unusually mild up to the present time, and the garden is still alive with flowers, of which the following is a list:—*Alyssum montanum* and *maritimum*, *Armeria fasciculata*, *Aubrietia purpurea*, *Anemone coronaria* and *vitifolia*, various kinds of Daisies, *Chimonanthus fragrans*, six large flowered Chrysanthemums, *Cardamine amara*, *Coronilla Emerus*, *Cistus corberiensis*, Marigolds, Wallflowers, *Escallonia nra* and *macrantha*, Strawberries, Christmas Roses, Candytufts, *Iris germanica* (just opening) and *stylosa*, *Kuiphofia Burchelli* and *Rouperi*, *Lychnis flos cuculi*, *Lamium maculatum*, *Lonicera flexuosa*, *Malcomia maritima*, *Mesembryanthemum*, *Mathiola incana* (single red and white, double red), *Pyrethrum Parthenium* fl. pl., Polyanthuses, common Primroses, *Potentilla alba*, *Ranunculus*, Roses—Hybrid Perpetuals (3 vars.), Tea-scented (2 vars.) Common China, *involucrata*, *Maria Leonida*, *monstrosa*, and Queen, *Sonchus oleraceus*, *Senecio vngaris*, *Sisyrinchium iridifolium*, *Laurustinus*, *Viola lutea*, and Pansy (five vars.). The shrubby Veronicas, too, are just now in excellent condition. Perfect flowers of all the plants just mentioned were observed in the open gardens on Christmas Day. Although not in blossom, scarlet and variegated Pelargoniums, *Calceolarias*, *Mignouette*, and other bedding plants are healthy, and in fair foliage.—W. W. SAUNDERS, Raystead, Worthing.

SREET TREES IN NEWINGTON CAUSEWAY.—On the motion of Mr. E. H. Bayley, the St. George's (Southwark) Vestry have determined to plant trees in Newington Causeway.

BEGONIAS FOR WALLS AND ROCKS.

THE back walls of shaded plant houses, which are generally unsuited for light-loving flowering plants, cannot be better utilized than by covering them with Ferns, Selaginellas, fine-foliaged Begonias (similar to that here represented), and graceful trailing plants of elegant habit. In many cases this has been already done with excellent effect, but perhaps never better than in the Ferneries at Manley Hall some years ago, where scarcely a bare inch of wall was anywhere visible, so dense and beautiful was the carpet of verdure which covered them. There are several ways in which these wall gardens may be formed, but the best which I have yet seen adopted is to cover the face of the wall with a coat of Peat and living Sphagnum Moss, 2 in. or 3 in. thick, these materials being held in position by means of zinc hexagon netting fastened firmly to the masonry. Under such circumstances scandent Ferns, Begonias of different sorts, Pothos argyrea, Tradescantia, Panicum variegatum, and trailing Aroids may be planted for immediate effect, and spores of quick-growing Ferns may be shaken over the moist surface as a preparation for future display. Frequent syringing is requisite, especially in dry, hot weather, until the plants have become established. In warm, shady plant-houses or conservatories these walls of

verdure are not only beautiful additions to the other arrangements, but they also serve a useful purpose in preserving the atmosphere in that humid and genial condition which is so essential to the welfare of choice decorative plants. B.

CLEMATIS SCREENS.

ALTHOUGH it is the fashion to erect screens of various kinds in the garden, it is not at all times that the screen proves more ornamental than the object sought to be hidden. A raised Fernery or rockwork may make an effectual screen, and yet be most hideous on account of its own deformity. A screen of evergreens is at once effective and pleasing, but it is not at all times possible to place such a screen in the narrow space at disposal. Probably no more thorough screen can be had than is produced by a close leafy growth of Ivy, but that is so wanting in parti-coloured hues, that its very sameness may at times become objectionable, whilst other creeping plants have little chance of existence if planted with Ivy, as the latter is often too robust and exhausting; thus, screens of vigorous climbers such as the Clematis, if not so effective for their special purpose in the winter, are at least very beautiful in the summer months, and can hardly be excelled in variety and interest. A further advantage may be found in the cheapness of a Clematis screen, as a few stout supports fixed securely at short intervals in the ground and covered with wire of a large mesh or in lengths placed at close intervals up the supports, will be found to be all that is required in its construction. Such wire can be purchased at a moderate price, and be fixed by any ordinary labourer, either by means of small iron staples, or by winding round the supports. I have just erected one about 6 ft. in height, and as the end posts are very firmly fixed in the ground, there is no difficulty in straining the wire to the requisite tension. The advantage of such

a screen for the development of the superb flowering qualities of the Clematis can well be understood to be greatly preferable to the practice of growing it upon poles; the plant in this latter case is far too cramped, and its flowers are too crowded to admit of their beauties being seen to the fullest extent. When trained to such a screen, not only is each flower visible, but if several varieties be grown upon it, the beauty of the floral development is much enhanced by the mixture of light and dark colours, and the many varied tints found in this useful hardy plant. If the screen be desired in the winter months, the previous season's growth may remain until the spring, but ordinarily it would be desirable to prune back not later than the end of the year, so that the strongest buds at the base of the plant might be induced to start into growth in the succeeding year. The Clematis is a gross feeder, and will well repay good cultivation and the application in the winter of rich top-dressings of rotten manure; under such conditions of culture the rapidity of growth in the spring is truly marvellous. A. D.

Cordylone vivipara as a Basket Plant.—It is to be regretted that this plant is not better known and more generally cultivated than it is, for few subjects are better adapted for conservatory decoration than this Cordylone when grown in hanging baskets. At the end of September last I filled two such baskets, putting half a dozen medium-sized plants in each. For about three weeks after being planted they were allowed to stand in a cold frame, and were then removed to a warm greenhouse, suspending them from the roof. They were here but a short time, when their flowering shoots began to show themselves, and a week ago they were removed to the conservatory, being then in full beauty, their long flexible shoots hanging gracefully downwards, and literally studded with pretty, white, star-shaped blossoms. As this Cordylone is perfectly hardy, I intend to plant some of it out-of-doors in the coming spring, and allow it to remain permanently. Of course, in planting its habit must be considered, and a position assigned to it where its pendent shoots will be seen to the best advantage.—R., *Enniskerry*.

Cypripedium barbatum majus.—This is an interesting plant when well grown, and in my opinion deserves more attention than is generally bestowed upon it. All large establishments, as a rule, possess a few plants of it, sometimes thriving remarkably well, and at other times very indifferently. Every one who has a vinery or greenhouse would do well to give it a trial, its cultivation being by no means difficult. It will succeed admirably in a compost of good maiden loam and peat, with plenty of silver sand and thorough drainage, and will produce early in winter a quantity of blossoms which will keep in good condition in a cool place for eight or ten weeks. I have some plants of it in flower here at present that have been in bloom since the first week in October, and they appear fresh now. They look remarkably well when associated with other flowering plants, such as Chinese Primulas, Poinsettias, Heaths, Epacris, and similar plants, and they are very useful for dinner table decoration or for vases.—E. M. DAVIES, *Llanover*.

Small-flowered Cyclamena.—I have a few choice Cyclamens which have grown well during the past summer, and which are well furnished both with bloom and foliage, some having from sixty to eighty flower-buds on a plant, the latter being in 48-sized pots; but to my dismay the flowers which open are so dwindly and small that I am quite puzzled to know what has gone wrong with them. I have been keeping them on a light shelf in the greenhouse in a temperature ranging from 45° to 50°, giving air on bright sunny days, and I have given them weak liquid manure about once a week to help them, but without effect. Have they had heat enough, or should I withhold the liquid manure?—J. E.

Sub-tropical Plants without Glass.—I have little or no glass, but should like some of these in my garden. I could get a frame or small pit, if necessary. I shall be glad of any information as to sorts, &c. [The best plan will be to select beautiful hardy plants of picturesque habit, such as the Bamboos, Pampas Grass, Yuccas, &c. These, with healthy young Conifers, &c., will go far to produce a good effect. With a pit, a frame, or, if the soil be warm and well drained—even without them you might grow Cannas, perhaps the most valuable of all fine-leaved, flower-garden plants. Some, like the Castor-oil plant, may be raised in a warm pit or frame, and plants of great value, when properly placed in the flower garden, may be raised with hardy and half-hardy annuals. Among these may be named Artemisia annua and the common Hemp. Best of all, however, are shrubs and trees with fine foliage, such as the Ailantus, Pawlownia, Catalpa, Rhus, &c., which can be kept in a small state if cut down every autumn. These furnish superb foliage.]

THE LIBRARY.

CROSS AND SELF-FERTILIZATION OF PLANTS.*

THIS is a valuable contribution to the literature of plant culture and improvement, containing, as it does, the results of the author's experiments in the cross and self-fertilization of plants during a period of nearly twelve years. Starting from the obvious and now generally recognised fact that most plants are adapted by diversified and effective means for occasional cross-fertilization, it might have been inferred from this alone that some great advantage was derived from such a process; and it is the object of Mr. Darwin's book, as he tells us himself, to "show the nature and importance of the benefits thus derived." The adaptation of flowers for cross-fertilization has occupied the author's attention for the last thirty-seven years, and the experiments recorded in the volume now before us were suggested by his having raised, for other purposes, two large beds of cross and self-fertilized seedlings of the wild *Linaria vulgaris*. "To my surprise," says the author, "the crossed plants when fully grown were plainly taller and more vigorous than the self-fertilized ones;" but as bees are necessary to the due fertilization of this *Linaria*, so that the wild plants from which these seedlings had been raised must have been inter-crossed during previous generations, it seemed incredible that the difference in vigour could be due to a single act of cross-fertilization, and the result, although apparent enough, was attributed to other causes. Further experiments, however, made with cross and self-fertilized seeds of *Mimulus luteus* and *Pomora purpurea*, a plant better known in gardens as *Convolvulus major*, both of which, unlike the *Linaria* and *Dianthus*, are highly self-fertile. In all these preliminary experiments, the apparent superiority was so much in favour of cross as against self-fertilized plants, that a more extensive and careful series of experiments was decided on, and these, as we have before observed, occupied nearly twelve years to carry out. It is essential to notice here that all the plants were artificially fertilized, the one set with their own pollen—seedlings of these being called "self-fertilized," and the other series with pollen from other individual plants, their seedling offspring being termed "cross-fertilized." The manner in which the experiments were conducted, as well as real or apparent sources of error, are carefully gone into, but the results obtained are uniformly in favour of the cross-fertilized seedlings, and especially so in the case of the plants fertilized with pollen from an entirely fresh stock grown under conditions of soil, air, heat, or moisture which had caused their characteristics or constitutional peculiarities to vary in different proportions from those with which they were cross-fertilized. This cannot be shown better than by reproducing the accompanying Table.

	Plants from a Cross with a fresh stock.	Inter-crossed Plants of the same stock.	Self-fertilized plants.
<i>MIMULUS LUTEUS</i> —the inter-crossed plants are derived from a cross between two plants of the 8th self-fertilized generation. The self-fertilized plants belong to the 9th generation.	100	4	3
<i>ESCHSCHOLTZIA CALIFORNICA</i> —the inter-crossed and self-fertilized plants belong to the 2nd generation.	100	15	40
<i>DIANTHUS CARYOPHYLLUS</i> —the inter-crossed plants are derived from self-fertilized of the third generation, crossed by inter-crossed plants of the 3rd generation. The self-fertilized plants belong to the 4th generation.	100	45	33
<i>PETUNIA VIOLACEA</i> —the inter-crossed and self-fertilized plants belong to the 5th generation.	100	54	16

N.B.—In the above cases, excepting in that of *Eschscholtzia*, the plants derived from a cross with a fresh stock belong on the mother-side to the same stock with the inter-crossed and self-fertilized plants, and to the corresponding generation.

* "The Effect of Cross and Self-fertilization in the Vegetable Kingdom." By Charles Darwin, M.A., F.R.S., &c. London: John Murray, 1876.

As the author observes at page 15 that he has met with no observations on the effects of crossing and self-fertilizing the individuals of the same variety, we may here the more fittingly allude to Mr. Gower's interesting experiments, made some years ago, and published in Williams's "Choice Stove and Greenhouse Plants," p. 31, where, under the head of "Fertilization," we are informed of the astonishing results obtainable by cross-breeding, especially in the case of spring, autumn, and winter flowers, which, being to a great extent deprived of insect agency, require artificial impregnation. The experiments here alluded to have especial reference to the larger production of seed and increased vigour in the resulting plants. "For example," says the author, "we found that the stigma of one flower fertilized with pollen from a separate flower, but growing on the same plant, yielded four times as much seed as when left to fertilize itself, and above one-half more than when artificially impregnated with its own pollen. Carrying the experiment still further, and bringing pollen from another plant of the same species, but which had not originally sprung from the same stock, we found that the produce was three times the quantity yielded under the most favourable circumstances of the other experiment, namely the fertilization by pollen from a separate flower of the same plant. The contrast was, however, greatest with the flower which received no aid whatever; for with the foreign pollen applied artificially, the yield of seed was finer in quality, and twelve times as much in quantity, while in the respective cases of fertilization with foreign pollen (that is, pollen from a different plant) and with its own pollen, the yield was five times greater in favour of the foreign pollen. This will be seen more clearly by the following Table:—

EXPERIMENT 1.	EXPERIMENT 2.	EXPERIMENT 3.	EXPERIMENT 4.
Produce of a flower not receiving artificial aid in any way.	Produce of a flower fertilized with its own pollen.	Produce of a flower fertilized with pollen from a separate flower grown upon the same plant.	Produce of a flower fertilized with pollen from a different plant of the same species.
25 Seeds.	60 Seeds.	100 Seeds.	300 Seeds.
Yield of Seeds one-twelfth that of Experiment 4.	Yield of seeds, one-fifth that of Experiment 4.	Yield of Seeds, one-third that of Experiment 4.	Yield of Seeds highest both in quantity and quality.

This experiment was repeated several times, insects of all kinds being most carefully excluded from the flowers; and though differing in some cases in the number of seeds, yet in each the proportions were about the same. Now, although we are not prepared to assert that the like results can be obtained in the case of every species or variety, yet, from other experiments we have made, we are certain that the yield of seed will be larger and finer when the flowers thus receive the benefit of a cross with pollen from a separate plant, and where insect agency is deficient, it should always be supplied by artificial means."

The different phases of cross and self-fertilization as recorded and tabulated by Mr. Darwin, are doubtless of the utmost value and form the substantial basis of this instructive work, but it is in the general results deducible from these that we may expect cultivators to be most interested, and the benefits derivable from these are collected in the last chapter, from which we cannot do better than make a few extracts. The first and most important of these conclusions is that "cross-fertilization is beneficial and self-fertilization injurious," as shown by the superior difference in height, weight, constitutional vigour, and fertility of the offspring from cross-fertilized flowers. In the case of such plants as *Reseda* (*Mignonette*) and *Eschscholtzia*, which are sterile with their own pollen, but fertile with that from any other individual, it is pointed out that these plants must have been cross-fertilized during a long series of previous generations, and the artificial crosses as practised by Mr. Darwin cannot have increased the vigour of the offspring beyond that of their progenitors. "Therefore," says the author, "the difference between the self-fertilized and crossed plants raised by me cannot be

attributed to the superiority of the crossed, but to the inferiority of the self-fertilized seedlings due to the injurious effects of self-fertilization."

Another important result from a practical point of view is that "after plants have been propagated by self-fertilization for several generations a single cross with a fresh stock restores their pristine vigour;" and especially is this restoration valuable since "the good effects are transmitted by plants to the next generation, and, judging from the varieties of the common Pea, to many succeeding generations;" but it would appear as if there were a slow decrease of those effects in each succeeding generation, since many of the old varieties of self-fertilizing garden Peas are greatly improved by crossing them with fresh stock. There are some plants (and, according to our present knowledge, *Ophrys apifera* is a notable example) which habitually are self-fertilized, and as this plant, so far as we can judge, is as healthy and prolific as its cross-fertilized compeers, at present it would be desirable to know whether cross-fertilization would not be injurious rather than otherwise in the case of this and other self-fertilizing plants. Most probably, however, much of this mysticism ament the advantages of cross and self-fertilization comes of our looking at plants from an artificial and restricted stand-point; for it seems to us to be a matter of some importance whether we consider plant growth as it exists naturally, or as managed for private ends by the cultivator; for we must never lose sight of the great fact that re-production is hurtful rather than beneficial to the plant as an individual. Mr. Darwin's experiments go to prove that but little or no good follows cross-fertilization between flowers growing on the same plant, but on this point we require further evidence, particularly in the first place, because Nature especially provides for this kind of crossing in the case of Lobeliads, Agaves of the spicate group, and Composites; and, secondly, because, as we have already shown, Mr. Gower and, we believe, also the late Professor Lecocq, to say nothing of other observers, have noticed beneficial results from this phase of cross-fertilization, although not in such a marked degree as when two individual parents were employed. One fact pointed out by Mr. Darwin strikes us as being so important that we quote it in full:—"Seeds often lie dormant for several years in the ground, and germinate when brought near the surface by any means, as burrowing animals. They would probably be affected by the mere circumstance of having long lain dormant, for gardeners believe that the production of double flowers and of fruit is thus influenced. Seeds, moreover, which were matured during different seasons, will have been subjected during the whole course of their development to different degrees of heat and moisture." By this we see that cross-fertilization between distinct or differentiated stocks may have been carried on naturally for ages, owing to the sudden exposure and germination of seeds long buried, and the same result might attend the promiscuous dissemination of floating or winged seeds, since plants so distributed would be liable to become cross-fertilized by contiguity to plants in an old colony among which they had thus, as it were, become accidentally placed. We here see how it is possible for gardeners to improve their seeds by sowing mixed seeds of a variety, a result easily attained by purchasing a quart of any Pea, Bean, or other seed from three or four seedsmen in different localities, instead of three or four quarts of any given variety from one seedsmen. This may give a little more trouble, but, as Mr. Darwin so well demonstrates, the results thus obtainable are worthy of extra cultural care, and to all seed-growers, for trade purposes more especially, is this book to be recommended. The fact of different species or families of plants affecting certain localities in which the soil, moisture, or shelter is suitable to their growth, also tends to foster cross-fertilization between distinct stocks or races, since a suitable seed-bed thus furnished serves in some measure to forward the development of seeds of similar plants. In conclusion, we may truly say that the volume now under consideration is one which no intelligent cultivator can afford to be without, and especially is this the case because, apart from the immense volume of facts or direct information which it contains, set down in a plain and systematic manner, there is also a vast amount of suggestive matter which rouses the attention of the reader and which induces him to collate his own knowledge

as he reads. This, as we take it, is one of the objects kept in view by the author when preparing the work, and we now leave the book to the consideration of our readers as the result of priceless labour and research extending over the sixth part of a lifetime. B.

SAFFRON CULTURE IN THE ABRUZZI.

At the Pharmaceutical Conference at Bristol, Mr. H. Groves narrated a botanical tour in the Abruzzi, a sea of mountains where the Apennines present their grandest chain. On the lower spurs of these mountains, at a height of from 2000 ft. to 3000 ft., the cultivation of Saffron has been carried on for many generations. The mountains are calcareous, and, except to the botanist who has roamed them, present a very barren aspect, only relieved by the Beech thickets which straggle up their flanks as far as the tree limit. The cultivated ground commences below the Beech thickets, and is but a little less stony than the ground above; however, Corn and Potatoes thrive well, and a little lower down the Saffron plots are established. Here the stones are removed as much as is possible in a soil that consists of little else, and the ground is well trenched to the depth of half a metre and prepared in August with animal manure, preferably that of sheep, so as to be ready for the planting of the bulbs in the following October. The bulbs are planted in ridges with intervening furrows, which for economy of soil are sown with Corn, as this crop is gathered before the Saffron flowers appear, and the furrows remain free as pathways for the gatherers; besides which they are so disposed as to drain the plot. In the latter part of October and the whole of November the crop is gathered. Women gather the flowers early in the morning, and remove the stigmata at their leisure. Several flowers usually grow from one bulb, in some instances as many as ten to twelve. Once planted the Saffron plots remain good for two years, at the end of which time they are dug up, and in the third year are planted with Corn, after which they may be used again for Saffron, although they seek to keep the plots shifting as much as possible. Cows are lovers of Saffron bulbs, and field mice would commit great havoc were they not looked after by the peasants, who keep small guns and traps constantly in the fields. Many of the wealthy landowners owe their position to Saffron dealing, which in reality is speculation, as the price per kilo ranges from 100 to 300 lire. The poorer cultivators sell at the price of the year, but the richer dealers set aside their Saffron in tins if the price does not suit them. Some seasons have yielded such profits that one year's harvest has surpassed the value of the land under cultivation; at others the cultivation would have ceased were not the beds of two years' duration, and consequently no expense entailed to wait the result of a second season. The adulteration of Saffron is carried out in various ways, the chief one being by mixing with it boiled and shredded beef, the shreds being stained with Saffron water and afterwards dried. The filaments of the stamens are also dyed in the same manner and intermixed. Another adulterant is an almost impalpable yellow earth found occasionally in the mountains; and finally, before taking the product to market, it is damped with wine or water. Dealers accustomed to buying Saffron avoid these adulterated specimens, so that the Aquilan or Abruzzi quality rules higher than any other kind, not excepting that of Spain.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Pimelea decussata in Ireland.—At Ballyzibbia, near Mallow, Co. Cork, the seat of Sir Henry Becher, Bart., is a plant of this *Pimelea* growing in the open air. It has stood in the same situation for the past four years, and has never received the slightest protection during winter. It is in perfect health, and produces its flowers freely in the month of June each year. It is in a very sheltered position, but, nevertheless, it has withstood some 14° of frost.—E. R. Q. P.

Hydrangea paniculata grandiflora.—So much has been said of this new Japanese shrub during the past year that little need be added now. It has, according to "Moore's Rural," stood 28° below zero unharmed. It begins blooming early in August, and continues until after hard frosts. The thyrses of flowers, first greenish-white, then white, then rose, often measure 1 ft. in length and 20 in. in circumference. Every stem being thus terminated, the striking appearance of an entire plant may be conceived. There can be no doubt that this is one of the most valuable of all perfectly hardy shrubs.

Pruning Fir Trees.—Does the Spruce Fir suffer from cutting? Will you kindly inform me which is the best time for pruning this description of tree?—M. W. [Conifers are seldom injured by judicious pruning, that is when pruning is absolutely required, and done at a proper time, viz., between September and November, according to the season. In all cases, the cut points should be sloped, cutting outwards and upwards, so as not to expose the cut surface to the sun or frost. In a dry summer pruning can be done at a much earlier period than during a cold, wet one. Extensive ranges of Spruce Fir hedges along the roadside in several parts of Perthshire are cut every autumn, and look as well and quite as compact as a hedge of Yew.—M.]

COTTAGE GARDENING.

Salads.

An effort is seldom made by the occupiers of small gardens to supply anything like a succession of the materials used for salad making, and yet there are often patches of bare ground sufficient in many gardens, if made the most of, to do this without much expense or trouble. A cottage gardener cannot afford to have any headlands round his small patches of vegetable or fruit ground. Mustard and Cress, Radishes, Lamb's Lettuce, and even Lettuces, may be grown in the margins and corners, or be taken as a stolen crop, so to speak, in the early growth of others that require more time, without doing any injury. All this of course implies the possession on the part of the cultivator of that thought and perseverance that prompts him to leave the beaten track and strike out an independent path for himself, and there is as much need for this in cottage gardening as in other things. The cultivator who thinks is hardly ever satisfied with things as they are, and there is nothing so perfect that may not be improved. There is no royal road to the possession of any kind of knowledge, especially practical knowledge; that at least must be acquired by steady persistent effort, by cultivating that faculty of "trying again" when things do not turn out exactly as we wish—that always ultimately leads to success.

Lettuces.

To commence at the beginning of the season, sow a few seeds in February of the Tom Thumb, or any of the small, quick-growing Cabbage Lettuces—the early Paris Market is an excellent kind—in a pot in a warm, sunny window if there be no hand-light or frame; place a handful of rubble in the bottom for drainage, fill up to within $\frac{1}{2}$ in. of the top with light, rich soil, make firm, sow the seeds thinly, and scatter sufficient fine, light soil over to just cover the seeds, then press the surface down with the bottom of another pot or something similar. If the soil be just kept moist, the seeds will soon vegetate, when the plants may be hardened off, and be planted out 8 in. apart in any warm corner. A pinch of White or Green Cos may be sown at the same time and be treated in the same way, only when planted out give each a square foot of space. Unless there are means of disposing of a portion of the produce, a very small pinch of seeds at each sowing will be ample. Little and often should be the rule. At the same time that the seeds are sown in the sunny window just a pinch should be sown in some warm corner in the open air: these will form a good succession to the plants raised in the window, and from this time to the middle or end of July sow a few seeds at intervals of every three weeks or so. The June-sown plants, if it can be managed, should be sown thinly, without transplanting, on some cool, partially-shaded border, for in hot weather both Lettuces and Cauliflowers, if transplanted, are more liable to bolt prematurely than if undisturbed. The Bath or Brown Cos should be the kind principally sown in July and August for autumn and winter use, as it is hardier and better able to resist cold weather than other kinds. A few seeds may also be sown about the 1st of September to stand in the seed-beds all winter to put out in spring. Small plants generally go through a severe season better than larger ones, but in very severe weather it is easy to lay a few fronds of Bracken over them when there is a sharp frost unaccompanied by snow, but when the ground is covered with snow, no other protection is necessary, as that is Nature's own covering, and, unlike all others, it protects without blanching or weakening. Although I recommend frequent sowings to be made, it does not follow that large quantities of seeds need be purchased. Probably in many, if not most gardens the same quantity of seeds now used, if divided into six or eight portions and sown at intervals through the season, instead of being all sown at once or at the most twice, would suffice to give a moderate succession. Of course some pains must be taken to place the seeds in a suitable position to germinate, and although Lettuce will produce a very useful crop under very moderate cultivation, yet to grow a first-class crop it requires as much skill and attention as it does to produce a prize dish of Potatoes or Cauliflowers. Mulching in dry, hot weather will well repay the trouble. Liquid manure, where it can be obtained,

will insure a quick, crisp growth; and, where neither are available, a frequent stirring of the surface an inch or so in depth will be of great service. All Cos Lettuces are improved by being tied up to blanch a few days before they are used, as are also some of the large, loose-growing Cabbage Lettuces. The Brown Cos from the July and August sowings for autumn and winter use should be planted out on a warm, dry site, and if covered up with dry leaves or Fern when nearly fully grown, and the plants themselves are dry, they will keep in good condition a long time, and will become white, crisp, and delicate.

Endive.

This is rarely grown in small gardens, but it forms a very desirable addition to the salad bowl in autumn and winter, especially if Lettuces be scarce or inferior. Sow towards the end of June (if sown early the plants are very likely to bolt before they are large enough for use) in drills 1 ft. apart, and when large enough thin out to 10 in. or 12 in. apart in the rows; the thinning may be planted elsewhere the same distances asunder. Sow again in July, and transplant the principal part in some open, well-exposed situation; the remainder should be planted in some well-drained, raised border. A few more may be sown in August if some shelter, such as a frame, can be found for them in winter. There are various ways of blanching them, viz., by laying boards or slates over the plants when they are full grown and quite dry; tying them up and placing inverted flower-pots over them, with pieces of slate over the holes at the tops to exclude light; covering them with dry leaves or coal ashes; or taking them up with balls of earth and storing them in a dark cellar—placing them, in fact, in any position not too damp to induce decay, and from which light can be excluded. Of course only a few should be blanched at a time, as this hastens decay, and they should not be blanched till they nearly fully grown. In other respects Endive requires much the same treatment as Lettuces. There are several varieties, but the Green Curled is the most useful.

Radishes.

Sow the Salmon Short-top or Wood's Frame on a warm rich border early in February, and cover with clean long straw or mats. As soon as the seeds come up the coverings should be taken off every fine day, and replaced at night until the plants are gradually inured to the weather. From March to September sow the French Breakfast—an Olive-shaped kind—at intervals of a fortnight or three weeks. The early and late sowings may be made on a warm border of light, rich soil. In very hot weather sow in a north or shady aspect, at other times sow in any open position. Quick growth is essential to mild flavour; therefore abundant watering in dry weather will be found serviceable.

Rampion.

This is scarcely known in small gardens, and I just mention it here as it proves a desirable addition to winter salads. Sow in May, in a partially shaded position, such as the west side of a wall or hedge where the soil is light and rich. The ground should be well prepared, made firm, and the surface smooth and level. The fine dust-like seeds must be thinly and evenly sown over the bed, which might be about 8 ft. long and 4 ft. wide, and the least possible covering of fine soil will be sufficient. The young plants when large enough should be thinned out to 3 in. apart, and the thinnings transplanted if required, taking care to insert the roots straight down. They will come into use in autumn, and will continue in season during the winter and early spring months. The white roots may be eaten like Radishes, or both roots and leaves cut up with other ingredients for salad.

Corn Salad or Lamb's Lettuce.

This grows well without much trouble in almost any soil. Sow in February or March for the first crop in drills 6 in. apart, and thin out to 4 in. asunder. They are best used when quite young. Sow again in May, June, and August under similar conditions. In gathering the winter crop only the outer leaves should be used, leaving the roots for further production, but in summer the whole plant may be cut up when young.

Mustard and Cress.

The culture of these is generally so well understood that little need be said respecting it. Sow thickly in drills from February to September as often as may be necessary to keep up the required supply. In hot weather sow in a shady position and keep moist by laying Rhubarb leaves over the drills until the seeds germinate. In winter they may be forced in any light position where the requisite temperature can be secured. In a warm kitchen or room a constant supply might be kept up without much trouble.

E. HOBBDAY.

A New Hardy Magnolia (M. Halleana).—Mr. S. Parsons,

junior, speaks with enthusiasm of this shrub in the "Country Gentleman":—"This plant came from Japan to America nearly twenty years ago, but continues very little known; indeed, hardly recognized in the country at large. The cause may be found partly in the general difficulty of propagating Magnolias, and partly in that lack of regard for plants that prompts acceptance of the meagre, second-hand information of dealers. All who see *M. Halleana* in our nurseries are delighted with its beauties. The first impression made is one of intense individuality. It rounds out and matures into a complete bush of symmetrical form and solid wood, and is a true member of the scrubby type of Magnolias. The same excellence appears also in unrivalled earliness and beauty of flowers. These somewhat resemble the Water Lily in the translucent whiteness of the narrow petals, and surpass all others in delicate, subtle odour. The leaves, of rich green, neither large nor small, are in agreeable keeping with the general habit, and, altogether, the effect produced is that of a noble plant.

Trees and Rabbits.

—Would it injure young trees to put tar round them to prevent rabbits from destroying them?—W. [Tar is objectionable, as it is injurious to young trees. A mixture of soot, sulphur, lime, and cow manure, made thin enough to be put on with a brush, will help to ward off the attacks of rabbits during ordinary seasons. Blood has also been found effective sprinkled at the base of the trees. Wire netting or tying Birch or Heath round the necks of the plants, is the only effectual remedy in severe seasons where rabbits are numerous, and where other food is scarce; but, where large plantations are made, these are troublesome as well as expensive remedies, and unless it is desirable to keep the rabbits, the best way is at once to take means to destroy them.—C.]

Influence of Forests on Ozone.—In a note by M. L. Fautrat in the "Bulletin Hebdomadaire," No. 475, of the Scientific Association of France, it is shown from observations made at Halatte and Ermenoville, that less ozone was observed in forests, particularly forests of Pine, than in the open country, and more ozone at a height of 46 ft. above the ground than near the surface.

TREES AND SHRUBS.

PICEA NORDMANNIANA IN WILTSHIRE.

THIS distinct and beautiful variety of Silver Fir was discovered by Prof. Nordmann growing on the summit of the Crimean Mountains; it was afterwards found to be common on the declivities of other mountains adjacent to the Black Sea towards the east, where it forms a majestic tree from 80 ft. to 100 ft. in height. Since its introduction into this country (some thirty-two years ago) it has proved to be one of the hardiest varieties of the Silver Fir. It commences growth late in spring, thus never suffering from the effects of spring

frosts—a great recommendation for planting in low-lying situations, where many of the less hardy Conifers do not succeed satisfactorily. It is slow of development when young, and inclined towards a spreading habit; but when once planted out into permanent quarters, and its tap-root fairly established in the ground, it begins to grow more rapidly, and soon shapes itself into a well-balanced tree. In suitable soils it makes an annual growth of from 15 in. to 18 in. Deep, heavy, rich loam, resting on clay or rock, is the most suitable formation for its healthy progress. The contrast in its pale green foliage in summer between the old and young growths, and the beautifully glaucous coating underneath its foliage, is very effective; while the silvery appearance underneath its leaves is hardly perceptible in young plants unless closely examined, but when the tree is older, and upwards of 20 ft. high, this glaucous appearance is at once in striking and beautiful contrast with the colour of the branches on the upper side. The timber of this tree is said to be harder than that of the Common Silver Fir (*Picea pectinata*). It is rather premature to

Nordmann's Silver Fir (*Picea Nordmanniana*).

form a decided opinion as to the quality of its timber; I however venture to predict that it will never be of great commercial value, neither do I think that it will ever attain to the noble proportions that belong to the common variety in Britain. The latter tree grows to a height of upwards of 140 ft., girthing 16 ft. at 5 ft. above the ground, and containing from 450 ft. to 550 ft. of timber; whereas *Picea Nordmanniana* only grows to a height of 100 ft. in its native habitats. Silver Fir timber does not command a high price—at the present time it is selling at about 1s. per ft.; Larch timber is worth one-half more; therefore *Picea Nordmanniana* can hardly be recommended to be planted with a view to its becoming a profitable timber tree; but, on the other hand, for

its ornamental character, planted singly or in groups amongst other trees, it is one of the best of the Picea family.

Longleaf.

GEORGE BERRY.

RHODODENDRONS NOT AMERICAN PLANTS.

In an article that appeared some time ago in a contemporary the impropriety of calling Rhododendrons "American plants" is alluded to. Rhododendron catawbiense, Ledums, Andromedas, Kalmias, &c., the writer of the article in question states, have "very naturally acquired the name of American plants—a term still in use, but one that conveys quite a wrong idea, and had better be discarded." He then goes on to show that grand as the *R. arboreum* from India is, it "could not exist permanently except under the protection of glass," consequently the hybrids from it are not American, because raised in England. I venture to ask what hardy Rhododendrons would be without *catawbiense*? It was once asked, "who reads an American book?" The writer of the article in question does not, as we shall soon see. "The work," he says of hybridizing, "has been accomplished almost wholly in England, though the Belgians have attained considerable success in that direction. In any case these beautiful hybrids are all emphatically European, and in quite a preponderating degree purely English, therefore the impropriety of calling them American plants. Hybridizing may have been practised, for aught we know, by Americans, but so far, in England, no results of it are known to exist." Now all thanks to the Waterers, the pioneers in Rhododendron and Azalea culture in Great Britain, and to Messrs. Rolisson, Standish, Noble, and other English cultivators, who have produced many fine varieties of this shrub: but where are the Belgian growers? Did not the late Mr. Van Houtte produce *R. fastuosum flore pleno*, which Mr. Waterer in his last catalogue says should be in every collection? In London's "Arboretum," under date of 1836, he gives a list of thirty-five varieties as the total produce of English hybrid Azaleas up to that time, including the Highclere seedlings, and ninety-five varieties of Belgian hybrids. And who produced the fine double Azaleas? Van Houtte, in his catalogue of 1856, enumerates upwards of 200 varieties of Rhododendrons, and 100 of them are of Belgian origin. For aught the writer knows, so far, in England, as the results are known to exist, America may be a myth. One would suppose that in writing upon the progress of horticulture, particularly upon hybridization, such progress would not be confined to one country, unless there were no means of knowledge accessible; but when we have had three or four horticultural periodicals published for forty years, it would seem that the information is ample, and not to be familiar with the subject is inexcusable for one who undertakes to write for the information of the public. Probably not one in ten of our American amateurs and nurserymen who saw Mr. Waterer's fine exhibition of Rhododendrons in the Centennial grounds in Philadelphia were at all surprised, unless it was at their great beauty, for all of us know what splendid varieties have been produced in England. Americans do not wait, like Micawber, for something to turn up, and in these days of railroads and telegraphs, for a writer to state that, for "aught he knows," such things do not exist because he has not seen them in England, only shows that though Greek may be at his tongue's end, he has yet much to learn in the way of horticulture.

Boston.

C. M. HOVER.

ORNAMENTAL BIRCHES.

Few trees are less fastidious as regards soils and situations than Birches; they thrive in the lightest and most porous of loams, in peat, and often in fissures of rocks on mountain sides under circumstances in which most other trees would fail. Of the known species and varieties the following may be regarded as the most distinct and most worthy the attention of planters of decorative trees:—

White or Common Birch (*B. alba*), so named from its beautiful silvery bark, is the species found wild in the mountain glens in Scotland, as well as all over the coldest and most inhospitable regions of Northern Europe, extending even to the verge of perpetual snow. In alluvial valleys and more sheltered districts it rises to the stature of a lofty tree, with a straight stem from 50 ft. to 70 ft. in height, amply furnished with long, wiry branches more or less pendulous, but on high exposed altitudes it dwarfs down to a mere bush. In Iceland and Lapland it forms the principal ligneous vegetation, clothing vast plains and valleys, and rarely rising higher than from 2 ft. to 4 ft. The leaves, which are light green when they unfold in spring, change to a darker tint in summer, and die off a bright

yellow. The flowers, which come out in February or March, are individually very minute, but are produced in great profusion in pendulous catkins. Both in a wild and cultivated state this tree occasionally exhibits a curious malformation, which some authorities attribute to insect agency, some of the branches forming themselves into dense, bushy tufts resembling birds' nests, and having an interesting and not unpleasant effect, particularly in winter, when, from the absence of leaves, they are seen to full advantage; country people call them "Witches' Besoms." The wood, which is white, close-grained, and susceptible of a high polish, is used in turnery, and a large quantity of it is annually made into charcoal. Though extensively planted on the margins of woods in bold exposed situations as a shelter to more tender trees, the Common Birch and its varieties rank among the most ornamental of park or pleasure ground trees; hence the frequency with which it is found occupying prominent places, both as single specimens and associated with other and rarer trees of denser growth and more sombre tints. The weeping form, which comes from seed along with that of a more upright growth, is probably the true species, as its bark is the more silvery of the two; at all events it is the one most in request for decorative planting, and doubtless that which, from its singularly elegant outline and the gracefulness of its spray-like branches, has so often attracted the attention of the poets. From a number of varieties in cultivation more or less distinct, the following may be regarded as the most interesting:—

B. A. LACINIATA PENDULA, known as the Fern-leaved Weeping Birch, is a very beautiful form which has the fine drooping branches of the species, with leaves deeply cut or lacinated.

B. A. URICEFOLIA, so named from its leaves resembling some of the species of Nettle, has foliage deeply lacinated, serrated, and hairy, and therefore very distinct from that of the parent. It is quite as handsome as any of the other forms, and richly deserves a place among the choicer trees.

B. A. PENDULA ELEGANS, sometimes called Young's Weeping Birch, is a most desirable variety, differing only from the species in its more decidedly weeping habit, which it assumes while in a comparatively young state. It is one of the finest of our ornamental trees, and cannot be too highly recommended to planters who, from limited space, have to confine themselves to a small selection.

Indian Birch (*B. Bhojputra*).—The singular name of this species is split by some writers "Bajjputra." It was first sent home in 1840 from the Garwal Mountains, in Kamaon, where in valleys at high altitudes, it forms a straight-stemmed, bushy-headed tree of from 50 ft. to 70 ft. in height. The leaves are oblong-acute, prominently serrated, and somewhat larger than those of the Common Birch. The bark is light brown, a feature which gives the tree a special value for decorative purposes. It cannot be regarded as the hardest of the species, and should never be planted in cold, exposed situations; in moderately sheltered districts, however, it is found to stand our winters without injury, and to grow with great luxuriance. As its merits become better known it will no doubt be more extensively introduced into collections of ornamental trees.

Sweet Birch or Mountain Mahogany (*B. lenta*).—This species is indigenous to a vast area in North America, extending from Canada to Georgia, and attaining heights of from 50 ft. to 70 ft. It has been cultivated in this country since about 1750. Its leaves are large, cordate-ovate, sharply serrated; and as they unfold in early spring they are covered with a minute, light-coloured pubescence. The flowers, which are in larger catkins than those of the Common species, have a delicate aromatic fragrance; they are at their best about the end of May. This tree furnishes the well-known American Birchwood, so much in favour with cabinet makers, who employ it in making many articles of furniture. It grows here very freely, and has much of that light, graceful aspect so much admired in all the other species, to which, though distinct enough to give a feature in woodland scenery, either standing alone or grouped with other trees, it has a general resemblance. From its tendency to early growth, and consequent liability to suffer damage from spring frosts, it should be planted on a dry soil and in a moderately-sheltered situation.

Dwarf Birch (*B. nana*).—This is a dwarf, shrubby species found wild on several of the mountains in the Highlands of Scotland, in Lapland, Sweden, Northern Russia, and in the colder parts of North America. In a wild state it is rarely seen above 3 ft. high; but cultivated in our gardens it grows with great vigour, and reaches heights of from 4 ft. to 6 ft. The leaves are orbicular, crenate, and reticulated. The habit of growth is dense, the branches much divided into short wiry branchlets. It is a quaint little shrub, useful for planting in front of those of more robust growth, and admirably suited for rockeries. It thrives best in damp, peaty soil, but will grow tolerably well in cool, stiff loam.

Paper Birch (*B. papyracea*).—This species is widely diffused over the colder regions of North America, where it grows to heights of from 60 ft. to 70 ft. It was first sent to Europe in 1750. The leaves are ovate-acuminate, serrated, and slightly downy on the under surface. The bark has a beautiful silvery whiteness, which is much admired, and is all the more conspicuous as the tree reaches a large size. The North American Indians make their canoes from the bark, stretching it in long wide strips over a wooden frame, sewing them together with the root fibres of the White Spruce, and rendering the seams water-tight with the resin of the Balm of Gilead Fir. The wood is hard, very durable, and takes on a high polish. With us it is a valuable tree for decorative planting, having a distinct-looking

A Weeping Birch.

appearance, the branches being more upright than those of the other species. It requires a dry and sheltered situation, as, like the other American species, it has a tendency to start into growth early in spring.

B. GRANDIS, a variety of the above, is a magnificent tree, differing from the species in having larger leaves and a more upright and robust habit of growth. It is as yet comparatively little known, but well worthy of being extensively introduced into collections of the rarer ornamental trees.

Poplar-leaved Birch (*B. populifolia*).—Another American species found in many parts of Canada and the United States, growing in dry, rocky places, and rarely attaining greater heights than from 20 ft. to 30 ft. It was introduced in 1750. The leaves are deltoid-acuminate, sharply serrated, and smooth. The bark is of a light cinnamon colour. Its habit of growth is broad and bushy, much denser than that of the Common Birch. It forms a neat dwarf specimen tree, thriving under the same circumstances as the other American species.

B. LACINIATA or **INCISA** is a very distinct form of it, the leaves being somewhat larger and much more deeply cut than those of the species.—“The Gardener.”

A FRENCHMAN is occupying himself in making a perfume from Peach leaves, which promises to become delicious.

THE KITCHEN GARDEN.

DOES SOIL WEAR OUT?

We sometimes hear it remarked that certain plots of soil are worn out and will not produce good crops, and the question arises, Is it the soil or the cultivator who is at fault? for the first and greatest requisite of good culture is to restore to the land the elements necessary for the growth of crops that have been extracted or obtained from it by previous ones, so that it may not decrease, but rather increase in fertility. Although applicable to all crops, whether in field or garden, let us confine ourselves to the kitchen garden under spade cultivation, as most likely to suffer from a constant repetition of crops of the same kind; and we have here a good practical illustration, for a portion of our kitchen garden has occupied the same site for hundreds of years, and is now as prolific as those portions that have been but recently enclosed. The natural soil is of considerable depth, and consists of a moderately light sandy loam, which will produce almost any kitchen garden crop in perfection, when first broken up, with but little addition as regards manure; but it is not at all the rule for such favourable conditions to exist on the spot selected for a kitchen garden. However, I never saw any soil so bad but that it was capable of yielding good results after careful cultivation, and in such cases old gardens are certainly preferable to new, as in soils of a stiff, retentive character it is a work of time to get depth of soil enough into a condition sufficiently friable to be suitable for many crops, while in the case of light, sandy soils the very opposite applications must be resorted to in order to give the necessary fertility and consistence to mature crops.

When a choice of substances containing manurial qualities is at command, much may be done to modify the character of any kind of soil. On stiff retentive land in which clay or heavy loam predominates, such substances as ashes or burnt earth, sand or grit, peat, leaf-mould, and stable manure, either used separately or combined, will, with careful cultivation and exposure to the action of frost, be highly beneficial; while light sandy soils that are usually poor in manurial matters, are equally benefited by the addition of clay or marl, cow and pig manure, salt, and such substances as tend to enrich the soil and retain moisture. When the above-mentioned substances are abundant, it will still be well to bear in mind that every kind of vegetable refuse that collects in a garden contains more or less a valuable manure, which will, if retained, be available for future crops. Deep pits or excavations sufficiently large to contain all that collects in one year is the plan we adopt, and advantage should be taken of frosty weather to wheel or cart the whole quantity into one ridge, the most decayed portion going to the top, and covering the whole surface with a good coating of garden soil. On this we plant Vegetable Marrows and ridge Cucumbers the following May, and always get abundance of fruit until the frost cuts them down, when the whole mass will be in good condition for applying to stiff soils, or as a top-dressing to orchard trees, for which purpose it is preferable to fresh manure, as it is immediately available as food to the surface roots, and tends to keep them within reach of atmospheric influences, thereby inducing fruitfulness, and at the same time increasing the depth of fertile soil. Trenching or deep cultivation is an important operation, whereby the worst soils may be eventually converted into fertile ones, and those of naturally good formation may be rendered exceedingly prolific, and kept in that condition for an indefinite period. Trenching should be performed according to the nature of the soil to be operated on, for when it has not previously been deeply cultivated, only a small portion of the bottom spit should be brought to the surface at first; but if well broken up, and plenty of manure incorporated with it as the work proceeds, in a few years it will be fit to bring to the surface for exposure to the atmosphere, thus securing fresh food for succeeding crops. Old kitchen gardens, or any lands that have been long under cultivation, and on which large quantities of manure have been applied, and a limited rotation of crops has been obliged to be adhered to, are greatly benefited by bringing the bottom spit entirely to the top, whereby a partial rest is given to them,

and fresh food supplied. For any crop that is intended to remain any length of time, as, for instance, Strawberry or Raspberry beds, &c., it is advisable to trench deeply and manure heavily, both previous to planting and when they are worn out. When it is possible to select the season for trenching, autumn or early winter is preferable, as the surface then gets thoroughly pulverised before spring seed-time arrives, and a good seed-bed is worth all the extra labour it takes to secure by the future development of the crop. The interval between successive trenchings depends very much on whether a rapid rotation of crops and high culture is adopted, or wider intervals for cultivation and lying fallow, with smaller applications of manure.

A decided improvement as regards the cropping of kitchen gardens has been pretty generally observed within the last few years, more especially as regards the grouping of certain crops, whereby their special wants may be more readily attended to than where a mixed system is followed. For instance, it was originally more the rule than the exception to see standard and bush fruit trees freely dotted along the margins of every quarter in the garden, whereas the rule is now to group crops that are stationary for a given number of years, such as bush fruits, Raspberry, Strawberry, and Asparagus beds, and to leave the quarters devoted to annual cropping entirely open. There is no necessity for separating them into distinct gardens, for, on the contrary, a quarter or square that has been long under vegetable crops will be decidedly benefited by a course of fruit culture, and *vice versa*. The requirements of various places necessitate distinct methods of cropping, and sheltered borders are obliged frequently to be cropped differently from the general routine of open quarters, in order to meet the demand for early vegetables. But a general rule may be advantageously observed, to follow heavy manuring and trenching with the most succulent moisture-loving crops, such as Cauliflowers, Cabbages, Peas, and Salads, and to succeed them with root crops that are apt to be rather injured than improved by fresh manures. There is a very general impression that crops in kitchen gardens of very long standing are more subject to disease and insect plagues than those in freshly broken up soil, but such is not our experience, as we find the presence or absence of such evils more affected by the variety of soil than the length of time it has been under cultivation, that is, if ordinary precautions be taken to guard against them.

JAMES GROOM.

Hechtan.

Jerusalem Artichokes for Stock.—The cultivation of Artichokes is being greatly extended in the Western States of America. Many cultivators prefer them to any other root for their cattle and hogs, and believe that they cause cows to yield a larger flow of milk. After the fact that they are excellent food for stock, Artichokes owe their popularity in large part to their being raised with little trouble. They are adapted to all soils, though the crop is more profitable from rich land. They are also very productive, yielding from 700 to 1000 bushels per acre. There is no insect enemy that makes the least impression on them, neither are they injured by the severe cold of northern winters, and rarely from the drought of summer. Like the Parsnip, they require no protection in winter.—C.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

The Golden Trophy Tomato.—This is a sport from the well-known Trophy, but it is a stronger and more rapid grower, more productive, and ripens a week earlier, continuing until frost. The fruit is almost an exact counterpart of the Trophy in form and size, of a light yellow or straw colour, occasionally faintly streaked with red; the flesh is firm and solid, containing but few seeds. Its flavour is entirely different from that of any variety with which we are acquainted, being free from the strong Tomato taste and fragrance which belong to most other varieties, having very little acidity, and when eaten raw without seasoning resembling in flavour some varieties of Apples. [Tomatoes free from Tomato taste are doubtful additions to the family.]

The Pigeon Berry (*Phytolacca decandra*), also called Poke and Garget Root, is not often planted in the vegetable gardens of this country, still, it is, according to "Moore's Rural," a valuable esculent, and deserves to be more extensively cultivated. It will thrive in almost any soil and situation, and may be readily propagated by dividing the old roots or from seed. The young shoots are used as a substitute for or in the same manner as Asparagus, which they resemble in taste. The sprouts may also be cooked in the same manner as asparagus, or as spinach, for greens. There is also an annual variety, the *Phytolacca*, known as *P. esculenta*, but the former is the preferable species, on account of being a perennial.

PLATE LV.

THE CATCHFLIES, OR SILENES.

(WITH A COLOURED FIGURE OF *S. PUMILIO*.)

Drawn by H. NOEL HUMPHREYS.

The genus *Silene*—of one of the pigmy forms of which the accompanying plate (prepared from a plant in Messrs. Backhouse's nurseries at York) gives a charming illustration—is one of considerable extent. Amongst the 200 species which it numbers there is one special section characterized by extreme dwarfness and compact Mossy habit of growth. So distinct is it that I have often wondered that it has not been separated from the *Silenes* and re-christened under a special generic title of its own. The plants included in this small section are known by the name of Moss Campions or Cushion Pinks—both appropriate titles. The genus contains amongst its numerous annual and biennial species few showy plants, but among the perennials there are various species of great beauty. Altogether the genus is—so far, at least, as our present knowledge goes—confined to the Northern Hemisphere; it is certainly true that there is one species figured many years ago in the Bot. Mag., and chronicled as a native of the Cape of Good Hope; but the history accompanying it gives no particulars as to its introduction, and possibly its habitat may have been recorded in error; be this as it may, it stands as a solitary exception. Southern and Central Europe must be looked upon as the home of the *Silene*, though a few species extend westward to America, a few eastward to Siberia, while a sprinkling of them will be found on the southern shores of the Mediterranean and in Asia Minor. The English appellation (Catchfly) originated doubtless in the excreted viscid fluid given out by the flowering stems, constituting a means by which small flies are caught in numbers.

The Stemless Section.

Pigmy Moss Champion (*Silene pumilio*).—So happy has the artist been in delineating the general outward appearance and beauty of this species that a detailed description is rendered almost unnecessary. To those who are familiar with our native *S. acaulis*, a distinctive character will at once be obvious, in the leaves being longer, more linear in shape, and less dense and compact in arrangement. The flowers are much larger, the petals being wider apart, and broken up towards the point into an irregularly divided and undulate margin; the calyx is tubular, and in its deep chocolate-crimson colour adds its quota to the general beauty of the flowers. It is a native of high altitudes on the Alps of the Tyrol, where it blossoms and grows freely; originally introduced in 1823, it, I fear, never became established in general culture, and was re-introduced some years ago by Messrs. Backhouse, but is still very rare in cultivation; nor, indeed, would its condition when seen lead one to suppose that it possesses a tithe of the vigour of the allied species from our own native mountains. In pot culture it completely failed with me. I apprehend that the position best adapted for its cultivation would be in a sunny nook of a rockwork amongst a mixture of firm peaty soil and sand, well secured with nodules of broken stone; and being a hard, woody-rooting plant, I would suggest that far greater success would be attained by getting seeds rather than plants from its native habitat, which latter always suffer seriously in transit. By means of these seedlings a fair chance would be given for the young plants to adapt themselves to such a change of circumstances as must necessarily occur between the Tyrolean mountain tops as compared with our lowland, artificial rockeries.

Stemless Moss Champion (*S. acaulis*).—This species possesses a hard, woody, branching root-stalk, the stem growth being exceedingly compact, each branchlet furnished with a dense arrangement of short, linear leaves, gradually tapering to the point, and ciliated at the base, but devoid of pubescence; the flowers are solitary, on stems so short as just to raise them above the dense foliage; the petals are entire as to their margin, and slightly notched at the points. The usual colour is a deep rosy-purple. Every one who has seen this plant in its native habitat, whether on the mountain tops of Wales, Cumberland, or in Scotland, must have been struck with its wonderful beauty in the month of June, when it forms a perfect carpet of blossom—here nestling high up amongst the broken fragments of rock, there spreading out in soft, cushion-like masses—thoroughly endorsing the appropriateness of its popular title, Cushion Pink. Under ordinary garden culture, to which it is easily amenable, it blossoms in May, but rarely are its flowers produced in

such wondrous profusion as in its native wilds. This plant may be readily increased by division of the tufty roots, or by seeds, which it produces sparingly. The flowers have a tendency to become dioecious, a characteristic which is occasionally to be found both in this genus and the closely allied *Lychnis*. There is a white variety—not uncommon—whose flowers are somewhat smaller in size.

Emerald Cushion Campion (*S. exscapa*).—Literally translated, this specific term is synonymous with that of the previous species; but, in fact, the flowers are so far stemless that they are perfectly embedded amongst the dense mass of foliage—their bright colours resembling rubies in an emerald setting. Possessing many of the characteristics of the former species, of which, indeed, it is considered by some authors as a mere variety, it is distinguished by the leaves being broader at the base, more fleshy, and devoid of the ciliated hairs; the petals also are narrower and devoid of the emarginate indentation at the top. In growth it is equally free, and retains a much brighter green colour as regards the whole plant throughout the season than does its close ally, *S. acanthis*, whose representative type it appears to be in the more northern regions, for it occurs in Norway and Lapland more abundantly than in the Swiss Alps, though by no means absent in the latter. I have been informed by travellers who have seen both species growing side by side in their native habitats that they may be distinguished with the utmost ease, even by a botanically uneducated eye, the same difference being noticeable under cultivation. I have come to the conclusion, therefore, that we are quite justified in recognizing its specific identity.

The Many-flowered Section.

Four-toothed Catchfly (*S. quadridentata*).—A diminutive and wonderfully floriferous plant, with small, lanceolate leaves, each blossom of the purest white, supported on stems about 3 in. high, and each petal regularly notched into four distinct blunt divisions or teeth at its extremity, the whole forming a tuft of unsurpassed loveliness and purity. This charming plant is a native of the Alps, and, though considered somewhat delicate, is perfectly hardy, but subject to the influence of damp rather than of cold. It seeds freely, and will readily establish itself by this means in the chinks and crevices of the rockery. I may here note that seedling plants established in small pots will survive the winter where large, vigorous-growing plants will succumb.

S. QUADRIDENTATA var. *QUADRIFIDA*, considered by some as a distinct species, is, I fear, only a slender form with smaller flowers, and the petals more deeply notched. When raised from seeds, which it produces equally free with the last species, amongst its progeny all sorts of gradations between the two types will be found, for which reason I think it better to consider it only as a variation.

Alpine Catchfly (*S. alpestris*).—This is recognised by some as a British plant, one or two specimens having been seen on one of the Scotch mountains; the authority, however, appears doubtful, and any one who is familiar with the persistent habit of the root-spreading propensities of the plant, can easily understand that if once established it would be very difficult to eradicate. In cultivation it forms a mass of underground stems, from which arise a few inches above the ground, tufts of smooth, lanceolate, deep green leaves, tinged with a chocolate shade. The flowers are borne on branching cymes 5 in. or 6 in. high, and are pure white, each petal being neatly and sharply notched into four lobes at the extremity, of larger size, but very similar in appearance to the previous species; the flower-stems are covered with dark, glandular hairs that exude a viscid fluid. There is a narrow-leaved form that is sometimes met with under the title of *S. saxatilis*, but that species, as described by Sims, and figured in the *Bot. Mag.*, belongs to quite a distinct section. The plant under notice is found in abundance on the mountains of Central Europe; it is equally well adapted for the front rank of the herbaceous border as for the rockery, having a vigorous habit of growth, and increasing readily by division and by seeds. This, and the two preceding species, are sometimes to be met with under the distinct generic title of *Heliosperma*, arising from the fact that the seeds are flat, circular in shape, and surrounded by a membranous ring, finishing off with a ciliated margin; hence the applicability of the name, which, literally translated, means “sun-seed.”

Elizabethan Catchfly (*S. Elizabethæ*).—This charming plant, from whose woody root-stock arises a mass of floriferous stems to a height of 8 in. or 9 in., has its stems covered throughout with a viscous pubescence, which is especially pronounced in the upper portion. The flowers are fully 1 in. in diameter, of a bright crimson colour, the limb or expanded portion of each petal being broad, very slightly bilobed, and irregularly notched round the margin. In general aspect it reminds one of a very compact-flowered *Clarkia*, with which its tint of colour exactly corresponds. It is a native of the Italian Alps

and the Tyrol, and blossoms in July. Its period of flowering is of considerable duration, owing, as in the preceding species, to the successional rather than to the simultaneous expansion of the flowers. It is a matter of no little surprise that so lovely a plant should continue to be so long a comparative stranger in our collections as it hitherto has been, although introduced some fourteen or fifteen years ago.

Saxifrage Catchfly (*S. Saxifraga*).—A slender-growing plant forming elegant lax tufts. The stems (single-flowered) attain a height of 8 in. or 9 in.; the petals are deeply notched, and, though the individual flowers are not showy, when combined in numbers they have a very effective appearance. They are French white in colour,

Saxifrage Catchfly (*S. Saxifraga*).

and are produced in succession, extending through the months of June and July. Native of the south of France. It is equally well adapted for the border as the rockery, growing freely in any ordinary garden soil. Being of a very tufty growth, it should be increased by seeds rather than by division.

Rock Catchfly (*S. rupestris*).—Very closely related to the preceding, differing chiefly in its narrower leaves and more compact growth. It is a native of the Apennines and the Vosges, where it abounds in dry, exposed localities.

Late-blooming Catchfly (*S. Schaftæ*).—A procumbent plant, producing from a tufted crown numerous leafy stems bearing large pink flowers toward their extremities; its leaves are ovate, lanceolate, sparsely covered with a short, somewhat rigid greyish pubescence. It flowers freely in August and September, when few other representatives of the genus are to be found. A native of the Caucasus,

Late-blooming Catchfly (*S. Schaftæ*).

and, although making an admirable rock plant especially valuable for its late-blooming proclivities, it answers equally well in the mixed border. It may be increased by division of the root or, still better, by seeds, which it produces very freely.

Pennsylvanian Catchfly (*S. pennsylvanica*).—A similarly dwarf plant to the preceding, of branching, semi-procumbent habit, the lower leaves of which are lanceolate, gradually tapering down to the base of a long petiole, and margined with short, somewhat rigid cilia; they have also a slightly glaucous colour; the upper leaves are few in number, linear-lanceolate, and widening towards the base, where they become almost connate; the inflorescence is loosely fasciculate, the arrangement, general appearance, and colour of the flowers reminding one a good deal of *Phlox ovata*. The calyx is almost cylindrical and viscidly pubescent; the petals are broad towards the apex, and, in place of being deeply notched, they are

almost truncate, that is, cut nearly square across, and slightly crenulated along the terminal margin; the stamens and styles are scarcely exerted; of the former, one-half are included within the flower, while the other half just protrudes beyond the narrow throat. As the name indicates, it is a native of Pennsylvania, and its rosy-pink flowers are produced in the months of June and July. This species is rarely met with in cultivation, at least I have not even seen it for the last twenty years.

The Inflated-calyx Section.

Caucasian Catchfly (*S. Zawadski*).—This English appellation I have adopted from the fact that it is sometimes met with in cultivation under the specific name of *S. caucasica*, and being a native of the Caucasus, though by no means the only one, it is an improvement on the hard Russian patronymic which I believe is its authentic descriptive title. It is a dwarf-growing plant with broadly-lanceolate, shining, light green leaves; the flower-branches are devoid of the viscid secretion so characteristic of the genus, as indeed are all the plants in this section. They acquire a height of about 9 in. The calyx is loose and inflated, with reticulated markings, and the flowers are white, deeply emarginate, and large in proportion to the size of the plant. It makes alike a good rockery or border plant, thrives well in any garden soil, and is much appreciated by slugs, who often devour the young shoots to the very core during the winter. It blooms in May and June.

Sea-side Catchfly (*S. maritima*).—This plant is supposed by some to be nothing more than a mere variety of *S. inflata*, which occurs frequently in inland hedgerows; but I hold that it is essentially dis-

Double Sea-side Catchfly (*S. maritima*, fl.-pl.)

tinct from that species, having grown them both side by side for many years without the slightest variation in the typical characters, the one (*maritima*) being essentially procumbent, the other (*inflata*), if obliged to assume that character, evidently does it against its will, being naturally erect, but dependent on adjacent support to counteract its own inherent weakness of stem. The leaves are ovate, lanceolate, and spatulate, of a decidedly glaucous hue; the stems individually are few-flowered, but are produced in such numbers that the plant becomes a trailing mass of white blossoms; the calyx is broadly inflated, and the limb of the petals is widespread and slightly bilobed; the flowers are much larger than in *S. inflata*. A native of Britain, and, though truly a sea-side plant in every sense of the word, like the Thrift or Sea Pink, it is sometimes met with alongside of our mountain rills, and under those conditions has received the title of *S. alpina*. The glaucous character is far from being so marked in the Alpine as in the sea-side plant.

S. MARITIMA ROSEA is an exceedingly pretty rose-coloured variation, with whose origin I am quite unacquainted; besides the difference in the colour of the flower it is less rambling in habit.

S. MARITIMA PLENA.—The double form, if it flower less freely than the normal type, amply compensates for it by the enormous size of individual blooms, which are extremely double. This variety makes a lovely rock plant, and ought always to be placed in such a position that its stems, borne down by the weight of blossom, may hang over the ledge of a rock; otherwise, if planted in a border, they get besprinkled with soil after every shower of rain. Producing no seeds, from the fact that all the parts of the flower are metamorphosed into petals in quite a wholesale manner, it retains its blossoms longer in perfection, and the flowering season extends over a much longer period than in the single form. It should be increased by cuttings struck in the spring in a gentle heat, care being taken to anticipate the removal of the cuttings by placing the plant itself in heat so as to start it into growth. The plant does not readily divide.

Fimbriated Catchfly (*S. fimbriata*).—This is an erect, strong-growing plant, whose flowering stems attain a height of at least 2 ft.; the leaves are broadly ovate, cordate, and sessile; the flower-stems are terminated by compact, branching cymes; the flowers are white, and their chief beauty consists in the finely cut, fimbriated edges of the petals, which have a very elegant, tassel-like appearance; the stems rise from a dense, compact root-stalk with such rapidity in early summer, that if not watched and staked in time they are liable to break over; and if they have not broken completely away in the first instance, they are still more liable to do so when raised from their prostrate position. It is a good border plant, and is a native of the Caucasus.

Flowers Erect, in Low-branching Cymes.

Cut-leaved Catchfly (*S. laciniata*).—An erect-growing plant, attaining a height of 15 in. or 18 in. The leaves are large, lanceolate, and acute, the whole plant covered with a short pubescence; the calyx is long, cylindrical, and rose-coloured; the petals are divided through the entire extent of limb into four linear segments each; the flowers are of a crimson-scarlet, varying to orange-scarlet, and, being large and laxly arranged, they have a very pretty and attractive appearance. It is scarce in cultivation owing to the fact that it does not seed freely—possibly our summers lack the intense heat and brilliancy of sunshine that it enjoys in its native habitat at the foot of Mt. Orizaba, in Mexico.

Virginian Catchfly (*S. virginica*).—This claims a very close relationship to the foregoing species, differing chiefly in its less erect habit, its broader leaves, and the presence of a rigid pubescence that gives the whole plant a roughness to the touch which the other does possess; moreover, the petals, though deeply notched in the centre, are only slightly divided, while the singularly linear divisional character is absent altogether in this species. The flowers are purplish-red in colour, and are produced in July and August. It is a native of the Southern States, and, culturally speaking, should have a damp sub-soil and full exposure to all the sunshine obtainable.

Royal Catchfly (*S. regia*).—An erect-growing plant, attaining, with its flowering stems, a height of from 2 ft. to 3 ft.; the entire plant is pubescent, the leaves lanceolate, acuminate, and scattered sparsely over the plant; the petals are very narrow, lanceolate, and undivided at the point—in this respect it is almost exceptional in the genus: the flowers are an intense scarlet, reminding one of *Lobelia fulgens*. It was discovered by Nuttall in the neighbourhood of St. Louis. I question if the true species be at present in cultivation, nor, indeed, has it been for years; there is, however, a comparatively worthless annual cultivated under that name, which belongs to a different section of the genus.

The Shrubby Section.

Shrubby Catchfly (*S. fenticosa*).—This evergreen plant acquires in its native habitat all the character and appearance of a neat and somewhat compact-growing shrub. The leaves are densely arranged, obovate, lanceolate, and distinctly acuminate, gradually narrowing down to the base, and of a leathery consistency, and of a bright and cheerful green colour; the flowers are large, of a deep rosy pink, produced on a short, three-branching cyme, and are developed in the months of May and June. Under favourable circumstances, where a too vigorous growth is not induced, it flowers all the summer through. Indigenous to Sicily and Southern Italy, where it affects the dry fissures of the rocks. For ordinary border culture it can scarcely be considered hardy, but its natural habitat may readily be imitated on the rockery; and, under such circumstances, it makes a persistent and moderately free-blooming plant. It is sometimes known under the specific title of *S. arborescens*.

The Semi-shrubby Section.

Tartarian Catchfly (*S. tatarica*) is of a semi-shrubby character, that is, it forms a thick, woody base, whence arise during summer its erect, flowering stems, which assume a spike-like appearance. The lower leaves are broadly lanceolate and smooth, almost sessile, and ciliated at the base; those of the inflorescence, which attains a height of from 2 ft. to 3 ft., become gradually narrower. The flowers are of a yellowish-white colour, and are produced on short secondary spikes in such abundance as to give a somewhat stiff contour to the entire plant. Its flowers expand fully towards night, but, unlike some other not very showy species that possess this peculiar habit, they are devoid of any perfume—I allude especially to *S. saxatilis* and *S. bupleuroides*, the fragrance of both of which is of the most delicate character.

S. CILIATA and *S. GREFFERI*, if not, as at present cultivated, identical, bear a very close relationship to each other. They both

form many branching, compact-trailing stems, covered with obovate-lanceolate leaves, which narrow rather abruptly into the petiole. In *S. ciliata* the margin of the petioles and the base of the leaves are distinctly ciliated, much more so than in the allied species; in both the upper leaves assume a linear character, and the flowers are white, produced in threes or fours, on long foot-stalks; the petals are deeply bifid. These plants are more remarkable for neatness of habit than for the abundance and beauty of their flowers.

Bolander's Catchfly (*S. Bolanderi*).—With this species, which I must class as a nondescript, I bring my enumeration to a close. My reason for giving it this title is that though it twice flowered with me raised from seeds introduced by my friend, Mr. Thompson, of Ipswich, owing to the depredation of slugs I never saw a perfect leaf. It blossomed, nevertheless, and a noble flower it produced more than 1 in. in diameter, on a stem, about 3 in. high, of a delicate pinkish-white colour, each petal being cut in the form of a trident. It would be rash with a plant so mutilated as mine was to assume that the true character was represented. I must therefore leave it to Mr. Thompson to supplement my article by his experience in this plant's general character and culture. JAMES C. NIVEN.

Botanic Garden, Hull.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Greenhouses in Winter.—Those amateurs who in a great measure attend to their own greenhouses at this season find the weather a continual source of anxiety, especially when their houses are small, as in such the heat fluctuates in accordance with the external temperature much quicker than in larger structures, which necessarily contain a greater body of air. Bright nights, with the wind from a northerly or easterly direction, are always doubtful, and often cause hesitation betwixt taking the trouble to light a fire with the objectionable consequences of making the house too warm should no frost occur, and ruining the health of the plants should the temperature sink so low as to admit frost. Both these extremes ought to be avoided if possible, especially the latter, but nevertheless should greenhouse plants happen to get frozen, much may be done to mitigate the ill effects, provided prompt action be taken. The first thing to start with is to set the fire going as quickly as possible to raise the temperature of the house before the sun comes upon the glass; and as soon as the thermometer inside indicates a degree or two above freezing, syringe the plants freely overhead with cold water, so as to wet the whole of the frozen leaves and stems, keeping the fire going briskly until the temperature rises to 40°, and maintaining it at that point till the leaves have become quite dry. So treated, many plants that at first would appear to be hopelessly injured, will suffer comparatively little; at the same time it is not advisable to submit tender plants to frost if it can be avoided.

Seed-sowing, &c.—Satisfactory results in gardening matters, more than most others, depend upon a timely commencement of operations, especially in seed-sowing, planting, cutting striking, &c.; for instance, to have a crop of any spring vegetable ready for use by a particular time, or, in other words, as early as the season will permit, in any given locality, it is indispensable that there should be no delay at the commencement of operations. Amateurs who are interested in gardening pursuits frequently express their surprise when they see the earliness and excellence of the different varieties of spring vegetables with which Covent Garden Market is supplied: I am not now alluding to the produce of the Channel Islands, the south of France, Spain, Portugal, the Azores, or other favoured climes, but to such as are grown by English market gardeners, who regulate their operations so as never to allow any delay to occur in putting in the ground seeds or plants for their early crops, further than the exigencies of the weather in different seasons influencing the soil in particular localities; in this matter amateurs would do well to imitate the practice of those market growers who are guided by the early or late nature of the soil with which they have to deal. To have early Cabbages, Cauliflowers, Potatoes, or Peas a week or two before one's neighbour is able to secure them enhances the pleasure of growing them, independently of the agreeable change they afford from the old winter productions. We very seldom experience a winter when the all but incessant rains have rendered the soil less favourable for receiving the seeds of early crops of Peas and Broad Beans than the present; and where the land is naturally heavy and adhesive, it will be advisable to wait for some time longer before putting in the seeds of these vegetables, for although so hardy as to bear any amount of frost, they will rot if the soil hold an excess of moisture.

Peas.—This season, even in light and moderately dry land, it will be advisable to take a little more precaution than usual to insure the success of the first sowing of Peas. The driest portion of ground at command should be selected, independently of its sheltered position or otherwise; this latter is of less importance than a dry bed. Instead of the usual shallow trenches being made, I should recommend the soil being drawn in ridges about 8 in. high, flat at the top, and 12 in. broad; they should be made by drawing as much of the soil from the whole surface of the bed as will form these ridges at a distance of 3½ ft. apart for such varieties as William the First or Sangster's Number One. Sow on the top of the ridges, covering with about 3 in. of any sandy, open material, such as old potting soil covered with 1 in. of ashes; or if this be not at hand, the ordinary garden soil mixed with one-third of its bulk of sifted coal ashes is a good substitute. As a precaution against mice it will be advisable to coat the Peas with red lead, or to lay under the covering of soil 1 in. of Gorse chopped fine on the top of them—where this can be had it is preferable to the red lead, as it helps to keep the seed dry until it has time to germinate. The lead is applied by simply sprinkling the Peas with water, just sufficiently moistening the surface to make the powdered lead stick when shaken over them, at the same time stirring them so as to cover the whole, and allowing them to remain for a day to dry before sowing. It is advisable to sow thicker at this early season: a quart of these early kinds will be found sufficient for a row about 18 yards in length. If the situation be at all exposed, as soon as the Peas appear above ground take as much more soil from between the rows as will form a ridge on each side of the Peas high enough to break the force of the wind. Do not tread on the land more than can be avoided, or in its present wet state much mischief will be done. Should the ground have been dug early in the autumn, as recommended in previous numbers of THE GARDEN, such crops as the above may be put in without trampling upon the soil at all by simply using a few boards about 10 in. or 12 in. wide that will reach across the bed; the little extra labour involved in their use will be amply repaid in the produce. Some will say, defer sowing until later when the ground is drier, but late sowing means late gathering; and even if a long frost should follow the seed being put in, it will be safe if the above method be followed. One of the best crops of early Peas I ever had was sown in this way the last week in the preceding year, after which a frost ensued that prevented their appearance above ground for ten weeks.

Broad Beans, where required early, should also now be sown. If the land be at all inclined to be wet, sow on the surface and cover as recommended for Peas, in which way it is evident the seed will be much better able to resist the effects of the excessive moist condition of the soil. In heavy, retentive ground, and in localities where the spring is backward, it is far preferable to defer sowing for at least a month.

Radishes.—Of these some should likewise now be sown. Choose a piece of land that slopes towards the sun. If such be not to hand, the slope should be made by moving 6 in. of the soil from the south to the opposite side of the ground. The advantage of the land lying in this way is, that the rains will run more quickly off, and the influence of the sun will be brought earlier to bear upon the seed. Level and rake the surface, sow the seed, and rake it in very slightly, or, what will be still better, just cover it with fine dry soil; then lay on about 3 in. of stable litter or straw, patting on the top a few Pea or Runner Bean sticks to keep the wind from blowing it about. If a bed of the short-topped variety and the Olive-shaped kind be sown at the same time, the latter will be ready for use by the time the former is consumed.

I have gone so far into detail in connection with the matter of sowing the above vegetables for the guidance of amateurs who have not had an opportunity of noticing how different the results are in a wet, season when means are taken to place the seeds in a position that will insure their being comparatively dry, to what takes place when they are in contact with a mass of soil from which the water has less chance of escaping.

Cauliflower.—In the south of the kingdom, on the coast, and in the more favoured localities, where Cauliflowers have a reasonable chance of standing through the winter, when planted at the foot of a south wall they will be more likely to survive the stacks of frost if boards be placed before them so as to break the force of the wind, and above all to shield them effectually from the sun when frozen, for they are frequently killed through the effects of a rapid thaw in the middle of the day being followed by the evening's returning frost. A little reflection upon this will convince any one that repetitions of such extremes are much more trying to vegetable life than is not quite hardy, than being for a time continuously frozen. It is necessary to take the same precaution in keeping the sun from young Cauliflowers. When in frames or under hand-lights a mat should be

thrown over the frame during the time that the sun is on the glass, and if a few Spruce, Yew, or any evergreen branches be placed firmly in the soil, in order to prevent the wind from disturbing them on the sunny side of the plants, they may remain until the frost is over. Lettuce, although not quite so tender as Cauliflower, should be similarly treated.

Potatoes.—Early kinds of these, from the present unusually warm weather, are commencing to sprout early; to prevent the sprouts becoming blanched and drawn up weakly, the Potatoes should be put in single layers in shallow boxes and placed where they will get a fair amount of light, and be out of the reach of frost; under a plant stage in a greenhouse, or in any empty apartment with a window in it, these necessary conditions will be secured.

Seakale and Rhubarb.—More roots should be put in to force; if the bed of leaves recommended for the purpose some time ago has been used, the heat by this time will be too much expended to induce growth and keep out frost; to remedy this surround the bed with 2 ft. of fermenting stable manure, letting it come half-way up the sides of the frame. When the first forced roots have yielded all the produce of which they are capable, if there be a deficiency of stock for making new plantations, they may be put in any spare corner and covered with ashes to keep them from frost till planting time comes.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

Jan. 8.—Cleaning Watercress stream. Sowing Sweet Peas under the protection of a hedge; also in pots; also Mustard and Cross regularly. Shifting *Nemophila* into flowering pots. Potting autumn-stuck *Heliotropes* and putting them into first Peach-house; also more Potatoes for frames. Putting in a few *Senecio* cuttings in order to get up stock; also Vine eyes, Croton, *Scatellaria*, *Petunia*, and *Calceolaria* cuttings in heat (this being the best time for spring striking). Putting *Dahlia*s into heat for cuttings. Planting standard Apple trees, Penny Royal, Fennel, Tarragon, Chives, and Lavender, and transplanting Lettuce. Putting Figs into heat, plunging them and keeping them at 58° at night. Putting into slight heat a few Wallflowers weekly; also *Kalmia latifolia*. Putting in 100 Keen's Seedling Strawberry plants weekly, and Endive once or twice a week according to the demand; also more Asparagus, throwing away first crop. Taking first Hyacinth in full flower out of heat. Putting *Salvia patens* into heat for cuttings. Placing Potatoes in loft very thinly to sprout for planting. Looking over *Pelargonium*s again and picking off damped leaves. Filling a pit with manure for cuttings. Putting leaves and manure into Cucumber-pit. Pruning late Vinery, except shoots on which Grapes are hanging. Gathering Czar Violets from pots.

Jan. 9.—Digging ground for Onions. Sowing some seeds of *Viola cornuta*, putting them into heat, and covering them with glass; also a box full of Red and White Celery; also Wood's Early Frame Radishes in pit, to come in middle of March. Finishing potting *Dendrobium nobile*, and beginning with others, using very fibrous peat. Planting Lilacs and Honeysuckle. Treading in newly planted Laurels, and watering several which were dry. Planting Lavender and Wallflowers. Putting a few Forget-me-nots in slight heat. Getting *Camellia*s to conservatory, and re-arranging it. Laying turf wherever required. Syringing late Peach trees with Tobacco-water for fly. Making leaf-bed for Carrots and Potatoes. Pruning old dwarf Apple trees.

Jan. 10.—Potting all *Odontoglossum*s except a few nearly in flower, using Sphagnum and peat; also some Sweet Briers. Putting in a good quantity of Carnation cuttings for blooming in October; also *Fuchsia*s in heat for cuttings. Planting some young Gooseberry trees. Top-dressing and potting *Cattleya*, using best peat. Giving Peach trees in pots some Standen's manures. Carting in soil (still loam) for Melons. Putting in Feverfew and *Chrysanthemum* cuttings.

Jan. 11.—Sowing seed of *Salvia patens*; also French Beans for second main Vineries. Potting Hollyhock cuttings. Putting in cuttings of *Achyrautes* and of Tree Carnations. Planting *Hypericum calycinum* under Oak trees, where they grow well. Beginning to plant Rhubarb. Shifting herbaceous *Calceolaria*s into their flowering pots. Covering up Celery with litter during frost only. Giving Maréchal Niel Roses in pots a rich top-dressing; also Oranges. Manuring Vinery and Peach-house borders with best manure, adding bones also to that of the Vinery, and covering all

with some long litter. Filling another two-light frame with soil for Carrots and Radishes. Cleaning Creepers in conservatory.

Jan. 12.—Sowing Syon House Cucumbers, and keeping them at 65 at night, 70° by day. Potting Potatoes, and placing them in Fig-house to sport. Potting off Cucumbers and Melons that were sown. Giving Roses planted-out in conservatory a top-dressing and watering. Plants ready for house decoration:—Lily of the Valley, *Narcissus*, *Heliotropes*, Hyacinths, Tulips, Callas, Sweet Briers, *Deutzias*, Scented-leaved and Scarlet *Pelargonium*s, and Mignonette.

Jan. 13.—Potting imported bulbs of *Lilium auratum*, and placing them in a cold, shady house; also some yellow *Calceolaria*s for early flowering. Pricking off seedlings of *Lobelia speciosa*. Planting *Hoteia japonica*, dividing the roots; also *Daphne Cneorum* and *Schizostylis*, and dividing them into small species. Putting in another forcing of Rhubarb. Looking over Apple and Onion stores.

Orchids.

For the next two months the Orchid grower will not have any great operations to perform, and during that time he must look carefully after the cleanliness of his plants, frequently examining each to see if the progress be satisfactory, and if not, attempting to better their condition by changing their position, &c. When an Orchid commences to suffer from bad health, a good remedy is to bring it nearer the glass, either by suspending it, or placing it on a shelf, which treatment will usually be followed by beneficial results. On account of the mild weather through the early part of December the temperatures of the cooler houses have not often been down to those recommended, but that is of little consequence: the temperatures previously given were intended as a guide and warning against excessive heat, and a few degrees above would not be injurious so long as they were caused by external warmth. The temperatures for January should be as nearly as possible those given for December. It must be borne in mind that pure air is the food and life of plants as well in winter as in summer, and that this is only to be obtained by judicious ventilation; therefore opportunities of giving air when it is clear outside should never be lost, but the ventilators should never be opened when the air in the house is considered (as in foggy weather) better than that outside.—JAMES O'BRIEN.

PLAN OF THE GARDENS AT BAGATELLE.

SIR RICHARD WALLACE'S garden in the Bois de Boulogne is a very distinct one, and has some of the best features of what the French call the English garden—we speak not of the portion near the house, which belongs to quite another style. In the picturesque portion of the grounds there are singularly quiet and charming scenes, and some pretty views from them into the adjacent country. An examination of the plan will show several long and quiet glades with well-planted groves and groups of trees. The views from many parts of the walks around are varied and pleasing. It may be noticed that the curvilinear walks, which are so offensive in the modern French garden, are not seen here. The walks are made to suit the grounds, whereas in the modern French garden the grounds are usually made to conform to ridiculous series of curved walks generally much more numerous than are needed. Here indeed, too, a few walks might be dispensed with, but the grounds are very extensive, and it may be seen by reference to the plan that several of the long walks pass through groves and are in them concealed. The fringes of these groves may be glanced at with advantage by such as are trying to modify the stiff and harsh outlines which garden plantations too often show. The grounds contain one of the most artistic small rock-gardens in France; it is on the margin of the water, and is very prettily clad with rock shrubs and creepers.

A Land of Cultivators.—Upwards of 5,500,000 men are reported in the census of 1870 as engaged in agriculture in the United States—373,453 in the State of New York alone, 375,107 in Illinois, 396,267 in Ohio, and between 200,000 and 300,000 each among other Northern or Middle States, in Indiana, Iowa, Kentucky, Missouri, Pennsylvania, Tennessee, and Virginia.

Frame Coverings.—What is the best and lightest protection for the glass of frames which could be easily made in an out-of-the-way district? I have hitherto used laths covered with mats and thatched with straw, but their weight after heavy rains becomes too much for the glass.—SOUTH ITALY.

PLAN OF SIR RICHARD WALLACE'S GARDEN IN THE BOIS DE BOULOGNE.

THE FRUIT GARDEN.

CULTURE OF GOOSEBERRIES AND CURRANTS.

Why take the trouble to renovate old trees—it may be asked—when young ones can be raised in their place? To which the answer is, that young trees cannot be got up in one year, or even two or three, and there are no doubt many who would be glad to know how to bring old and feeble bushes back to a state of vigour and fertility when they are not prepared to raise a fresh stock of young trees, perhaps to leave them to another tenant as soon as they are becoming useful. We have ourselves reason for being well satisfied with the results of "renovation" in very old subjects, such, perhaps, as would have been considered fit for the rubbish-heap only, but which have for many a year since yielded the most abundant crops. In fact, though young trees, two-year-olds from the nursery, were planted at the same time, the old ones still bear the main crop. A dozen years ago we found these old bushes growing as hedges round the vegetable quarters, the Gooseberries being planted in some places against espalier fruit trees, which they hid altogether. None of them, we should think, were less than thirty years of age, and most of them were probably more. They were in the last stage of feebleness, especially the Red Currants, some of which were quite beyond redemption. There were about one hundred and fifty bushes altogether, and as they had to be removed, and we could ill afford to dispense with them at the time, poor as they were, it was determined to give them another chance. With this view, a north border for the Gooseberries, and a quarter for the Currants, were trenched over in November. Afterwards holes from 6 ft. to 8 ft. apart—for the bushes were large—were taken out, and into the bottom of each was dug about a barrowful of good soil or decayed manure, and about as much was reserved for filling over the roots when planting was done. Before November was out all the bushes were taken up without any balls to their roots, for such could not be had with them, and transferred to their new quarters, mulching them well with rotten leaves. At the same time they were pruned, and had their centres opened out by the removal of many of the old limbs which had become much too crowded. The following season, about midsummer, a few of the Gooseberries withered and died, and ever since one or two have gone off in the same way annually, owing to old age, no doubt; but, with these exceptions, all have done well. None of the Black Currants died, and only one or two of the Red ones did; but the old limbs of the latter kept going off from time to time, and were replaced by young ones from the bottom, so that most of these are now composed of new branches from the old roots. All are now as vigorous looking almost as our young bushes, and appear as if they were good for any length of time. It may be stated that the bushes bore fruit, but not of large size, the summer after they were transplanted, and plentifully the year following. These remarks, it is hoped, will show that old trees may be dealt with summarily, and without fear, when it is desirable to renovate them; but, of course, it is not always needful to transplant, though that is undoubtedly the best way to give them a fresh start. Still, top-dressing the roots with fresh, rich soil or manure will invigorate them wonderfully, but it must be done liberally and continued annually for a time. The advantage of transplanting is that the trees make a fresh lot of roots altogether, and they have plenty of room to grow in the new and unoccupied soil.

Young Trees.

All the Ribes class are easily raised from cuttings, but, as nice young bushes two or three years old can be had from the nursery for a comparative trifle per hundred, it is cheaper and more convenient to buy them. As all require the same culture as regards soil and situation, &c., it is not necessary to speak of Gooseberries and Currants separately, except in the matter of pruning, which will be noticed by-and-by. Before speaking of buying, however, the preparation of the ground must first be alluded to. Any ordinary good garden soil suits the Gooseberry and Currant, but a pure friable loam is best for them, and in ground much charged with humus it is the best manure also that can be applied—if not in sufficient quantity to the soil, at least to the roots in planting. A rather moist

and deep soil is also preferable to one that is thin and dry, aphid and honeydew being the result of dryness at the root more than anything else. The ground should be prepared by trenching 2 ft. or 3 ft. deep, but manure, if given, should not be buried out of reach of the roots. The best way is to trench the ground first, and afterwards dig the manure in deeply, taking care to secure a good opening. Loam from the fields, either arable or pasture, should be given to light or old garden soils, and sand and leaf-mould and such like materials to soils of a clayey texture and, in abundance, for a tenacious soil is the worst for the Gooseberry. Bones, if they can be afforded for the purpose, are also excellent; in fact, it is hardly possible to over-manure any of our small fruits so as to injure them, for all ripen their wood with such certainty that they never fail to bear good crops unless when injured by frosts. The ground having been got in readiness, the sooner the trees are planted after the 1st of November the better, but planting may be done at any time during the winter when the weather is open and moist. Young plants, about two or three years old, and with clean, straight stems about 9 in. long, should be selected, but they should be looked over, and any suckers rubbed off that are found upon the stem. To save room the bushes may at first be planted 3 ft. apart each way, for it is assumed they are allowed a quarter to themselves; and when it becomes necessary to afford them more room, which they will require in four or five years at the most, every other row can be removed, and every other plant in the rows that are left, which will give each bush 6 ft. of space each way. In this way more varieties can be planted than otherwise could be, and when re-arrangement becomes necessary, a re-election can be made of the sorts which are found to succeed best or which are most appreciated. In planting the roots should be buried 4 in. or 5 in. at least, and about the same length of stem should be left above ground, so as to keep the branches out of the soil and prevent them rooting and throwing up suckers, which are always troublesome under such circumstances. If the plants get one good tread about the roots with the foot before the hole is quite filled up, it will keep them firmly in their places, and no stakes will be required. After planting a good thick mulching of loose rotten manure should be applied to each tree, and it should be renewed, if needful, before summer, in order to keep the roots moist and encourage growth. Other and subsequent root culture consists in forking the ground over annually between the rows and about the roots, but not too deeply, stirring the surface with the hoe to kill weeds, and, whenever practicable, in mulching the roots with short Grass or decayed manure during the summer, particularly in dry seasons. The advantages of this practice at such times can hardly be over-estimated. Regular dressings of manure, whether it be from the stable or cowhouse, or fresh loam from the field, should be forked in about the roots about once every two or three years; mulchings, if regularly given, compensate to a great extent for the want of manure.

Pruning Gooseberries.

There is only one good way of training and pruning Gooseberries of the bush form, and it is very easily understood. Beginning with the young bush from the nursery, which will, perhaps, be furnished with from three to six shoots, the operator must prune, so as to have them all pointing outwards without crossing each other, taking care to leave the centre of the bush open. Bought plants are not always methodically pruned but they should be put into shape when planted, if a portion of the branches have to be sacrificed. The shoots which are retained should be shortened back to from 6 in. to 9 in., according to their vigour, and with an eye to the symmetry of the bush. All varieties are not of the same habit, some growing erect, and others like the red Warrington, after a spreading form; but all conform to the same system of pruning. After the bushes have got fairly established, the shoots had better not be shortened back at all, but only thinned out pretty freely, always preserving the balance as evenly as possible, taking care to keep the centre open, seeing that all have space enough, and that they grow outwards. With vigorous bushes, the knife should be used freely, and a sufficiently thinned bush should look almost like a skeleton

when finished. No artificial spurs—that is, spurs formed by leaving a bud or two of the shoots which are removed—should be left; but such shoots should be cut clean off at the back. The plan of leaving the bearing shoots their entire length induces the formation of natural buds in quantity upon the old wood; whereas spur-pruning only promotes the growth of spray, which chokes the bush up in a single season.

Red Currants.

These should be kept open in the centre like Gooseberry bushes, and shaped in the same manner; but with the Currant it is preferable to shorten the terminal shoots back at pruning time to from 6 in. to 9 in. according to their vigour. The side-shoots too, or laterals, should not be entirely cut away as in the Gooseberry, but cut back to $\frac{1}{2}$ in. to $\frac{1}{4}$ in. from their base, to induce spurs or buds. The Red Currant is not so apt to produce spray as the Gooseberry. Trained in this way, the limbs of the bushes become eventually not unlike Vine-rods—spur-pruned—and their treatment is much the same, the young shoots which grow from the spurs only needing to be shortened back annually, and a portion of the leader left. It is well, however, to leave some of the young shoots which push from the bottom, to bring them on to take the place of the older ones, or such as may die.

Black Currants.

This sort differs from the Red Currant and from the Gooseberry in its habit of growth, and must be treated differently. The fruit is borne in greatest quantity upon the previous year's wood, and pruning must be conducted with a view to the preservation of the young growth, which should not be shortened at all. In fact, Black Currant bushes should only be thinned, and have their centres kept tolerably open. Long and old branches that are getting bare below should also be removed, and others brought up from the bottom to fill their places. No spurring or shortening is necessary, but shoots that have to be removed must be cut away altogether, and all others left as they are.

Bud Destroyers of the Gooseberry and Currant.

Bullfinches and others of the finch tribe are the most destructive in this respect, and the bullfinch is by far the worst. A couple of bullfinches will destroy all the buds on the bushes, and consequently the prospect of a crop, in a cottager's garden, in two or three days, probably before they are observed to be about the place, and a brood or two will ruin all the quarters in a large kitchen garden, if the bushes be not netted or protected in some way. They begin their attacks generally when the buds begin to push, and invariably, so far as we have observed, they take the bushes before them in the most methodical manner, always beginning at those nearest to their place of shelter, and advancing as they exhaust the supply. It does not pay to net the trees against the birds alone; but where netting is regularly practised to protect the fruit, the nets should be put on early in the winter, supported in a substantial way, and left on till the fruit is gathered, or all the year round. We have tried this plan, but the expense for nets was great, as they soon rot if left out the greater part of the year. The cheapest plan is to engine or syringe the trees well with water, in which soot, lime, and particularly red lead has been stirred. If the red lead is sufficient just to colour the bushes, it will stop the birds, but the dose must be repeated two or three times during the winter and spring.

Gooseberry Caterpillar.

This is the only other serious plague the cultivator has to contend with; but it can be effectually overcome by the application of hellebore powder applied either by hand dusting or with the syringe after mixing it with water. The last plan is by far the most effective and convenient.—“Field.”

Cure for the Phylloxera.—The most interesting paper read at the last fortnightly meeting of the Société Centrale d'Horticulture de France on the 14th ult. was that by Mousieur Sabatié, of Libourn, a rather extensive Vine grower in the neighbourhood of Bordeaux, who has invented a mailed glove composed of interlacing rings of thin galvanized iron with which to rub carefully the bark of each Vine in

Vineyards affected with Phylloxera at a time when the eggs have been freshly deposited in the interstices, an operation which he finds effectively destroyed the eggs; out of a Vineyard of 70 acres experimented on by him during last season, forty acres on which he was able to use his gloves enjoyed almost complete immunity from this pest, while the remaining thirty were almost destroyed. These gloves at present cost from 13 to 14 francs each, but in a little time when they come into general demand M. Sabatié hopes to be able to reduce their price to 12 francs or even lower. Such gloves are also admirably adapted for removing the Moss from Apple trees, and are provided with a chain and hook confuting them at the wrist so as to suit them almost to any sized hand.—W. E. G.

Want of Colour in Mrs. Pince's Black Muscat.—I have grown this Grape now for six years, and I must confess that I have been unable some seasons to get it in good condition. The flavour is excellent, and it is an abundant cropper, but the difficulty consists in getting that beautiful bloom on the bunches which is so desirable in all black Grapes. I have one Vine planted in a mixed house at the warmest end; this house is assisted with fire-heat about the beginning of March, and the Grapes on this Vine always colour the best, which leads me to think that Mrs. Pince requires a longer season to ripen than is generally allowed it; for, being a late Grape, it is generally kept back as long as possible, and only assisted with fire-heat after the Vines start; and if the autumn prove dull and unfavourable, so that the bunches are not finished off before September, very little bloom can be put on after that. I have likewise two late houses planted chiefly with a few Vines of Lady Downes, which have always finished off to perfection, but Mrs. Pince has not satisfied me in colour in those late houses; three parts of the berry colour very fairly, but the other part remains a dull red. There are a few who speak favourably of this Vine, and some who pronounce it the best late Grape in cultivation; but a far greater number complain of its besetting fault—bad colour. Perhaps there are two varieties, a fact which I think has been mentioned before. I intend to commence earlier this season, and see what effect that will have, for Mrs. Pince is a very superior Grape to Lady Downes, as far as flavour is concerned; but it is evident that it will not finish off with the same treatment as Lady Downes. A few hints from any of your readers who have succeeded, or failed, will perhaps enable one to arrive at the proper treatment which this otherwise excellent Grape requires in order to give it the same finish as its companion, Lady Downes.—J. A. H. G.

Experiments in Keeping Apples.—It is worth while to try experiments now in keeping Apples, as they are easily performed, and the results may prove valuable. We have found by frequently repeated trials, that Apples stored in an outhouse opening north till nearly the first of December will keep for several weeks, and sometimes even months, longer than if taken at once to the cellar as soon as picked from the trees. They are kept cool through the last half of autumn. Much may be gained, as well as learned, by keeping one or more thermometers in the fruit room, and swinging the windows open wide enough to bring the temperature nearly down to freezing at all times. At the same time, the exclusion of air-currents is an important assistance. One hundred Apples, wrapped merely in tissue paper, kept longer for this reason than a hundred exposed; hence, also, the great advantage of packing in dry sawdust or in pulverized plaster. The temperature is thus kept more uniform, and the fruit may be placed in a colder room without danger of freezing; wrapping each specimen in this paper first would be useful. Where dry sawdust is easily obtained it is well worth trying, either in open barrels or boxes. It is the exclusion of air that keeps Apples better in barrels, and this, according to the “Country Gentleman,” would be one of the best modes if the first decaying specimens could be seen and removed before tainting all the rest.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Coe's Late Red Plum.—This, according to the “Country Gentleman,” is the best very late Plum, when it ripens. The tree is very hardy, and profusely productive, and the fruit succeeds well in a large number of seasons. Where early autumn frosts occur, it would be of no value. It ripens early in October, and continues good for some weeks.

Good Pears.—Will you kindly favour me with the names of a few good Pears for planting on walls and in open quarters?—C. [The following kinds of Pears deserve especial notice by those about to plant in open quarters or on walls. They are all well-known kinds, and will invariably give satisfaction in almost any soil or situation. Those marked with an asterisk do best on a wall:—Citron des Carmes, Baronne de Mello, Beurré Diel, *Beurré Brown, *Beurré Sterckmans, Beurré d'Amanlis, Beurré Superfin, *Bergamotte d'Espéran, *Duchesse d'Angouleme, *Easter Beurré, Flemish Beauty, *Glor' Morceau, Jargonelle, Knight's Monarch, Louise Bonne of Jersey, *Marie Louise, Thompson's, Urbaniste, Passe Colmar, Williams' Bon Chrétien, and *Winter Nellis.]

BERRY-BEARING PLANTS.

THE extreme scarcity of the berries of the Holly this winter has been very generally felt by all whose duty or business it is to furnish Christmas decorative material. Whilst it is impossible to excel the Holly when in good berry for this particular use, it is evident that some substitute is worth cultivation to supply the demand for berries should the Holly crop prove a failure. The present season has found the Cotoneaster superbly fruited, its large berries glowing on the walls like masses of pearls; indeed, this plant seldom fails in the production of a rich and abundant crop of berries. If it were grown largely for the purpose of furnishing a supply of its rich red clusters at Christmas, it is probable that a ready market would be found for them, and the cutting of these would probably facilitate the production of a crop in each successive season. It is worthy of consideration whether this plant might not be worked upon clean young stocks of the Hawthorn, and so induced to develop neat, standard, berried heads. How beautiful these would be for house or domestic decoration, besides remaining fresh and vigorous for a long time! Some of the freest berry-bearing Hollies might be also worked as standards for a similar purpose, and no doubt would prove a useful addition to floral decoration. Some of the Silver and Golden-leaved kinds would be effective even if devoid of fruit, but it is notorious that the bright scarlet berries considerably enhance the value of plants or branches. We have already heard of a successful attempt to work the Mistletoe upon the Hawthorn stock, and so produce neat berried heads. It is needless to say that such plants, if largely and successfully grown for market, would meet with plenty of eager purchasers. The Solanum also furnishes one of the most charming families of winter-berried plants, all of which can be grown with great ease, and, unlike others previously mentioned, can be raised from seed in great abundance. As bush plants, the varied forms known as Weatherill's Hybrids cannot be excelled, as these develop berries in rich profusion, and, if well grown, are equally well covered with foliage. The conical-shaped-berried kind is specially pleasing and prolific, and worthy an extended cultivation. Best of all as a standard plant is the pseudo-capsicum variety, as it grows in that form naturally and produces handsome beads on stems from 15 in. to 20 in. in height. When full of berries and placed here and there amidst dwarf plants, the effect produced is at once pleasing and varied. With such a wealth of berry-bearing plants as now exist there need be no future absolute dependence on the uncertain Holly for a Christmas supply. A.

Insect Fertilization.—Mr. Boulger states (see p. 515, Vol. X.), that I have confused pollenization with fertilization. In another place I have been told that I should use the word impregnation for fertilization, but fertilization best expresses what most of us mean; at any rate, I am quite sure that the self-pollinated flowers to which I refer are not only abundant seeders, but that the seeds are abundantly fertile. Mr. Boulger tells us that "Wistaria has been shown by Messrs. Torrey and Gray ("Flora of North America," i., 291), to be mostly infertile, except as regards its cleistogamic blossoms." Torrey and Gray do not say so. I doubt much whether Wistaria ever produces such flowers. Our species—*Wistaria frutescens*—sometimes seeds in great profusion and sometimes not at all, though visited by insects freely in both cases. If I were to use the language which your correspondent quotes from Dr. Gray, I might say, "It is quite possible that the other cases brought forward by him may bear a different interpretation," but I regard such sweeping inferences, to say the least of them, as ungenerous. As, however, Dr. Gray must object to hasty and erroneous quotations, as well as to hasty generalization and imperfect observation, he will probably himself correct this strange warping of his own work. The only cleistogamous Papilionid native of the United States that I remember as I write is *Amphicarpæa monoica*, but this will surely not be quoted in the interest of insect fertilization. If colour be for the purpose of attracting insects, I suppose the rosy-white flowers are visited. I do not remember clearly how this is, but I do know that the only fruit I ever saw came from the cleistogamous flowers.—THOMAS MEEHAN, Germantown, Philadelphia.

Early Cinerarias.—What is a good time to sow Cineraria seed in order that the plants may be in flower about the middle of December?—J. E.

DWARF SCARLET BEGONIA.

(B. DAVIS).

THIS, although one of the smallest of all the Peruvian Begonias, is undoubtedly one of the most floriferous and brilliant, and as such deserves culture wherever Begonias of the half-hardy, tuberous-rooted section are grown for decorative purposes. The obliquely-cordate leaves grow in tufts near the surface of the soil, and are hairy on both surfaces. The flowers are borne three together on graceful radical scapes, which vary from 3 in. to 8 in. in height, the male flowers being about 2 in. in diameter, and of the most vivid orange-scarlet colour. The female flowers are rather smaller, but equally dazzling in colour. The specific name appears to have been given to this plant in compliment to Mr. Davis, one of the most successful of Messrs. Veitch's travellers in Peru and other parts of South America; but the plant must not be confounded with a variety of the *B. insignis* group, which is, or was, grown at Kew and elsewhere under the same name. It is not yet distributed, but when obtainable, it will soon become popular, being one of the most distinct and brilliant of all decorative plants for pot-culture, and one whose bright colouring will doubtless soon be

Begonia Davisii.

infused by the hybridist into the rosy and crimson varieties and sub-varieties of the *B. Veitchii-boliviana* group. The plant was first exhibited and received a first-class certificate at the Royal Horticultural Society's meeting held on August 2 of the present year. B.

Standard Roses in Pots.—Where there is a demand for cut Roses early in the spring, and these have to be brought forward in Vineries or other fruit houses, standard plants will generally be found the most useful shape, as, owing to their heads standing out in the full light, both flowers and foliage during short days come stronger than on dwarfs. They are also most suitable for conservatory decoration, as they can be placed in positions in borders amongst permanent plants, where their naked stems can be hidden, and thus be rendered more effective than small dwarf plants. Standard Roses may be kept in health for many years in 8-in. or 10-in. pots, by annually shaking them out in autumn, shortening their roots a little, and re-potting them in clean pots of the same size. Good loam, well enriched with thoroughly decomposed manure, is the most suitable compost in which to pot them, and if the loam be very adhesive, a liberal addition of road sand will be a great improvement.—W. S.

Alsophila plumosa.—This new Californian Fern is now in good condition at the Victoria Nursery, Holloway. It does not appear to grow so robustly as some other kinds, but its foliage is beautifully light and elegant, and it will doubtless prove to be a valuable addition to our list of Tree Ferns.—M.

USEFUL WINTER-FLOWERING STOVE PLANTS.

Now that Chrysanthemums in cool houses are all but over, there may still be had at this dull season, where the convenience of a stove exists, many bright and cheerful plants upon which to look, if a little tact and forethought have been brought to bear on their cultivation during the past summer. Nor need we look for new things wherewith to make a display; on the contrary, many of the best have long been occupants of our stoves, and are difficult to beat as far as general decorative effect is concerned. For winter-flowering subjects I prefer small pots, and give liquid manure as a compensation for want of root-room. *Poinsettia pulcherrima* has often grand heads of bright floral bracts that measure 1 ft. across, and that will keep in good condition for six weeks or two months, according to temperature. This is a plant of easy culture, and one which takes up no valuable space in the stove till autumn, and then it is all the better for being elevated close to the glass. My plan is after flowering to dry the plants off by placing them on their sides under the stage of the early Vinery, near where the hot-water pipes enter. After they become quite dry and the place gets too warm for them, they are laid under the stage of a small house used for bedding and other soft-wooded plants, till nearly midsummer, when they are cut back, shaken out, and reotted into the same sized pots (32's), using a compost of two-thirds good turfy loam and one-third well-rotted manure, with a dash of sand. They are then placed on the stage of the same house close to the glass, and when sufficiently established we generally put them out in a two-light frame; as they grow we raise the frame on bricks if required, which has the effect of hardening their wood and keeping them short-jointed. They should never be allowed to flag from want of water. If large bushy plants are needed they must be started earlier and the points may be stopped once. These, if inserted singly in small pots as cuttings, and plunged in bottom-heat, will make capital little plants. I prefer them to eyes for this purpose. I should add that the plants should not be left out after the nights get cold, or they will lose much of their foliage. Another well-known plant is *Euphorbia jacquiniiflora*, whose light and elegant sprays of scarlet flowers hanging over other plants materially enhance the general effect without injuring anything beneath them. As these go out of bloom they may be cut back a little, and kept drier than usual for a time till they commence breaking freely. When the young shoots are long enough they may be taken off with a heel and inserted in small pots, placing three in each, and then plunged in a brisk bottom-heat; cuttings of this and the preceding should be allowed to dry a little before insertion. They will require careful attention for a few weeks as regards moisture, or they are apt to damp off. When sufficiently rooted they are shifted just as they are into 32-sized pots, in which they flower. The soil should be free and open and the pots well drained. As the plants become fairly established I place them in a cooler house, keeping them close to the glass, where they get plenty of light and air; they are stopped once or twice during the summer. Young plants of this are always preferred. *Plumbago rosea* is another useful winter plant, for, though its individual flowers are rather short-lived, it produces large numbers of them in succession. Then we have several Gesneras, the old *G. zebрина* being a very good one for flowering through the dullest part of the winter if started in autumn. These, interspersed with other plants, have a lively and striking effect, but their beautiful foliage is better seen when in a more isolated position. I have used them for table decoration, their fine leaves being very attractive under artificial light. These plants delight in warmth and plenty of light, and thrive best in peaty soil with the addition of a little well-rotted cow manure, finely-broken charcoal, and a liberal admixture of silver sand. The *Amaryllis*, too, is a first-rate plant for winter work, its large Lily-like blooms being always admired. This might be grown in quantity, as it is a very accommodating plant. A 6-in. pot will answer for one of the smaller-bulbed kinds for several years with an annual top-dressing, and such plants sometimes yield as many as three spikes each. They like a rich, tenacious soil. Where sufficient numbers of plants exist, a few may be introduced to the stove or forcing-house about once a fortnight, starting about the beginning of November. Care should be taken that the plants started earliest one year

are the first to begin with the next, for in course of time, if this be attended to, they will acquire the habit of starting into growth with very little exciting about the time when they are wanted. *Thysacanthus rutilans* is a valuable winter-blooming plant, the crimson, tube-shaped flowers on its long pendent racemes looking at a distance as if suspended on very thin cords. Large plants of this can be grown from cuttings in one season; but, being a strong-rooting subject, it will require more pot-room than many others, though a good-sized plant of it may be grown in an 8-in. pot. It will do in a cooler house during the warmest months, but must not be left out too long, or it will lose most of its leaves. In room decoration, if elevated in the centre of a group under artificial light, associated with white *Epacris*, white *Primulas*, and the like, it is sure to be appreciated. *Centropogon luccanus* and *Eranthemum pulchellum* are both useful old plants that will succeed under similar treatment, the *Eranthemum* being especially welcome on account of its bright blue flowers. *Libonia floribunda*, though not generally treated as a stove plant, if placed in heat now will quickly open large numbers of pretty little scarlet and yellow *Cuphea*-like flowers, which are more valuable now than later in the season; it will make bushy little plants in one year from cuttings. Then there are several good old winter-flowering *Begonias* well worth more attention than they often get; these will generally be found to flower better when grown through the summer, with more light and air than the regular occupants of the stove receive; this treatment renders them hard and short-jointed, and consequently more floriferous. These are a few of the best among winter-blooming plants, and I venture to say that with some of each tastefully arranged among fine-foliaged plants and Ferns, with the addition of some light-flowered *Bouvardias*, yellow *Ocuidiums*, and other late-blooming *Oreohids*, such as the several *Calanthes*, *Lycaste Skinneri*, *Lælia autumnalis* and *anceps*, *Dendrobium moniliforme* and *nobile*, *Odontoglossum Alexandre*, &c., fringed with a few small *Epiphyllums* and small hanging plants of *Panicum variegatum*, *Lycopodiums*, &c., we might have a group that could not be easily surpassed at a more favourable season of the year. T. J. CRANE.

The Species of *Anigosanthus*, a genus of Australian plants of much beauty and interest, appears to be greatly neglected by plant growers. They are great favourites of mine, and I have tried various ways of cultivating them. They do fairly well under cool greenhouse treatment, with plenty of water, during the growing season. They do better, however, if placed out-of-doors during the warm weather in summer, setting the pots in a pan of water to the depth of about 1 in. or a little more. The water pan should be put in a sheltered but open situation, and the plants should be removed back to the greenhouse before the autumn frosts commence. Under this treatment they flower freely and keep healthy. I believe, however, that the species of *Anigosanthus* are much more hardy than cultivators generally expect, as the following experience will show:—During the winter of 1875-76 a plant of *Anigosanthus Manglesi* was left in its water-pan and overlooked; a hard frost set in, so that the air temperature was 22° Fahr., and the water in the pan was frozen more than $\frac{1}{2}$ in. in thickness. The plant then came under notice, and was at once removed to a cold frame and kept from further frost. This hard treatment seemed to arrest for a time all the energies of the plant, but it gradually came round, and is still living, and I think will make a strong plant in another year.—W. W. SAUNDERS, *Raystead, Worthing*.

Roses for a North Wall.—A correspondent (see p. 564, Vol. X.) inquires for a good red Rose for a north wall. My house faces the north, and I grow successfully against a trellis on it *Baronne Haussmann*, dark red shaded; *General Jacqueminot*, rich velvety-red; *Vicomte Vigier*, crimson; *Prince de Portia*, rich velvety-red; and Knight's new climber *Princess Louise Victoria*, a delicate blush with a pink centre. They are all Hybrid Perpetuals, and grow 10 ft. in height; they bloom freely in summer and autumn, and the quality of the flowers is good. If I had to plant over again, I could not improve the selection. The border is well manured, and manure-water is freely administered during the hot months.—H. T., *Bedale*.

A Lamp-heated Hot-water Apparatus.—Messrs. Dietz & Co. have invented a new circulating hot water stove which is likely to prove useful to amateurs who have small houses or frames to warm. It is simple in construction, (as will be seen by a representation of it in our advertising columns) easily lighted, cheap, and durable. It is heated

by a paraffin lamp, and is so constructed that a chimney can be easily placed on the top in order to carry off noxious gases arising from the oil. A pint of oil will last for about twenty-four hours, and the cotton only wants renewing once in two or three months. It will, no doubt, be found useful by those who require a cheap and ready means of excluding frost from small conservatories, or for expelling damp from rooms.—S.

New Gas-heating Ventilating and Lighting Apparatus.

—Messrs. Henderson & Son have now at work in their nursery, at Pine Apple Place, a newly-invented gas stove which promises fairly to become a great boon to people who possess small greenhouses, conservatories, &c., in which the ordinary modes of heating cannot be practically applied. The chief points in favour of this stove are its rapid heating properties, its simplicity of construction, and its elegant appearance. It is easily moved from place to place, and being supplied with two burners each furnished with a glass globe, it affords a good light. It moreover purifies the air of the room or house in which it is used, and does not injure even the most delicate flower though placed close to it. It is the best gas-heating apparatus which we have yet seen.

The Floods and the Trees at Fulham Palace.—The overflow of the Thames during the last few days has destroyed some of the trees in the grounds at Fulham Palace. On New Year's Day an Acacia, 50 ft. in height and with a girth of 12 ft., fell with a crash on the roof of one of the buildings at the Palace and did considerable damage; happily the rooms were unoccupied at the time, or the consequences might have been serious. Large Elms, too, growing in the immediate vicinity have sunk under their own weight, owing to the saturation to which the soil has been subjected, and ultimately fell to the ground, and many more will in all probability follow, unless a change in the weather shall quickly take place. The Acacia destroyed was one of the best trees of the kind in the country.

—At Southampton the tidal floods have done much damage, especially in the grounds belonging to Mr. Kingsbury, of the Bevois Valley Nurseries, on the south-eastern side of the town, where many acres have been submerged. The water forced its way into all the greenhouses and hothouses, and did great damage to valuable specimen plants and thousands of young seedlings in pots.

—The damage caused by the snowstorm of the 23rd and 24th ult. is very great in this locality; branches of trees 1 ft. in diameter were lopped off, Rose arches were broken down, and evergreen trees and shrubs levelled with the ground.—R. B. FULLER, *Fitzroy Park, Highgate.*

SCOTTISH SEED AND NURSERY TRADE ASSOCIATION.

At the annual meeting of this Association, which took place the other day in Edinburgh, the President in the chair, there was a good attendance of seed merchants and nurserymen. During the year it was stated that no case of adulteration had been formally brought before the Association, but the acting committee had anxiously considered the propriety of approaching the Government as to the amendment of the present Seed Adulteration Act. The Secretary stated that the existing Seed Adulteration Act was inoperative, in consequence of a public prosecutor having been omitted to be provided for. He had, at the suggestion of the committee, prepared the heads of a Bill which assimilated the provisions of the existing Act to the provisions of the Food and Drugs Adulteration Act of 1875. By this Bill it was provided that all parties adulterating seeds, either by killing the vitality of seeds or dyeing them and mixing these with other seed, should be fined in a sum not exceeding £50, and that the second offence should be deemed a misdemeanour to be punished with imprisonment. In the course of a conversation which ensued it was suggested that a memorial should be prepared on the subject for presentation to the Lord Advocate, and that a deputation should be appointed to wait on his lordship and urge his attention to the matter, with the object of endeavouring to get the Government to take up the question and pass a really effective Act. Mr. David Syme said that the mere fact of the Association desiring to take the steps indicated would be a strong deterrent to unscrupulous people offering adulterated seeds for sale. He moved that it be remitted to the acting committee to take what steps they saw fit for approaching the Lord Advocate in order to get the mind of the Government upon the question of a new effectual Bill. Mr. Hunter thought that if the Government would not take the matter up, the Association, as an association, might take up a case of adulteration, and try it under the existing Act. In this manner it might be demonstrated whether the Act was workable or not. Mr. Muir Crawford, Leith, said that he had made inquiry in Germany, France, Belgium, and other continental countries from which seed was brought to this country, and in neither of them was there a special law against adulteration, so that seed merchants here were pretty much at the mercy of foreign adulterators. However, adulteration in London and other parts of England was more to be feared.—Mr. James Welsh, Edinburgh, pointed out that if the Association took up a case and tried it, and failed, owing either to the unworkable nature of the Act or other causes, they would render themselves liable to an action for heavy damages.—The Chairman

said that he had had a conversation on the subject with a member of the Government, who stated that he would do all in his power to get the Government to make a representation to foreign Governments on the subject of seed adulteration.—Mr. Syme's motion was eventually agreed to, and it was determined that the Acting Committee should seek an interview with the Lord Advocate. The question of tree seeds which would not germinate being sold to members was also under discussion; and it was further remitted to the Acting Committee to consider the propriety of co-operating with the leading London seed merchants in defending vexatious and needless action by customers as to the value of seeds represented by crops. Officers for the ensuing year were then appointed, and on the motion of Mr. Sadler, Glasgow, it was remitted to the Acting Committee to consider the propriety of drawing up, in conjunction with the law agent of the Association, a non-guarantee clause for seeds to be adopted by the members of the Society.

THE KYRLE SOCIETY.

To the Editor of THE GARDEN.

SIR,—I am desired by the Committee of "The Kyrle Society for Bringing Beauty Home to the People" to thank you for the interest you have taken in their Society as well as for your kind permission to make known some of its objects through your columns, of which they gladly avail themselves. The Society has been set on foot with the view of bringing the refining and cheering influences of natural and artistic beauty into the homes and neighbourhood of the poor in our large towns. It is proposed to decorate workmen's clubs, mission rooms, and other rooms used for social purposes; to give oratorios and concerts in poor neighbourhoods; above all, to lay out as gardens any available strips of waste ground; and to encourage the cultivation of plants not only in windows, but in areas and backyards. For this purpose donations of money will be gladly received by the secretary; also gifts of roots, seeds, and bulbs, and of cut flowers for distribution. More valuable even than donations will be the personal help of those who have any experience in town gardening in laying out to the best advantage such bits of ground as are at the disposal of the Society. Any persons feeling sympathetically with the objects of the Society may become members, and their names will be enrolled if sent to the secretary. No subscription or donation required. A short report is printed every quarter, giving an account of what has been done during the past three months, and of what is projected; also of what form of help is most needed. All members desirous of receiving these reports may have them sent on payment of 1s. a year. M. PICKTON, Hon. Sec.

14, Nottingham Place, W.

P.S.—I should like to add that small city gardens have already been made in Lambeth, Marylebone, and Whitechapel. The latter, situated in a miserable court in that district, was liberally supplied with bedding-out plants in the summer by Messrs. Veitch & Sons, King's Road, Chelsea, who have also most kindly sent us Evergreens and Creepers for it this autumn, as well as a large quantity of window plants for distribution among the poor of the neighbourhood.

NOTES AND QUESTIONS—VARIOUS.

The White Drooping Broom (*Cytisus filipes*).—Few plants are more graceful and useful for conservatory decoration than this when grafted on clean straight stems of the common *Laburnum*, so as to form standards. In this way they grow very freely, and when their long, thread-like branches are thickly studded with pure white, Pea-shaped flowers, they are both effective and pretty.—M.

Angræcum sesquipedale.—A fine specimen of this in the Royal Exotic Nursery at Chelsea is now furnished with from seven to ten unusually large, pure white blossoms, and there are yet several more to open. The flowers, which have the good property of lasting in good condition for a considerable length of time, are highly desirable at this season of the year, when white flowers are especially valuable.—S.

Odontoglossum Andersonianum.—This rare Orchid is now in flower in the Pine-apple Nursery. Its blooms resemble those of *Odontoglossum cirrhosum* in form and size, but the spots and markings, instead of being of a purplish-blue, are of a reddish-brown colour. It is, however, a very distinct and valuable variety, and when more plentiful will doubtless be found in most collections of Orchids.—S.

Fumigation.—I have done this for many years as follows:—I take some large sheets of brown paper, wet them in a solution of sulphate and water (1 oz. to a gallon of water), and when dry I cut them in squares from 12 in. to 18 in.; I then spread as much as is required of the dry Tobacco evenly over the paper, then I roll it up tying it loosely in the middle, put it in a small flower pot, light both ends, and leave it to do its work.—O., *Cirencester*.

Sizes of Conifers in Cornwall.—In my remarks (see p. 102, Vol. X.) I inadvertently omitted to mention three trees, viz., *Abies Brunoniiana*, 29 ft. in height, planted in 1856, *A. canadensis*, 31 ft. in height, and *Pinus patula*, 26 ft. in height, planted in 1857. The last is the handsomest as well as the most graceful of all the *Pinuses* we have, but it requires a sheltered place and some slight protection in very severe winters. I would recommend the *Abies canadensis* or Hemlock Spruce, and the *A. Brunoniiana* to those about to plant, and who do not require large-growing trees. *A. canadensis* is with us a very handsome plant.—W. NANSICAWEN, *Culdroick, Menheniot, Cornwall*.

Soil for Ferns (see p. 565, Vol. X.).—Many Ferns will doubtless grow in peat, but the majority of them produce fine fronds in loam, to which has been added leaf-mould and sand. We have a fine plant of *Pteris tricolor*, which for years, when potted in light peat, scarcely made any progress, but during the last two seasons, when it has been in nothing but loam, leaf-mould, and sand, it has produced a splendid head of richly-colored fronds. Although by no means a new plant good specimens of this Fern are comparatively rare.—J. GROOM, *Henham*.

No. 269.]

SATURDAY, JANUARY 13, 1877.

"This is an art
Which does mend Nature; change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

FREE-BEARING PEARS.

It is generally conceded that no other fruit varies so greatly as the Pear does in different aspects and soils, and hence the conflicting testimony that is frequently borne as to the merits or demerits of the same variety when grown in different localities or under different conditions as to soil and aspect, more especially as regards the latter. Were it necessary, I could name a dozen kinds that are, when grown on walls, so totally different from the same kinds grown on standards in the same garden, that none but those unusually well versed in fruit lore would ever take them to be identical; taking, however, all the above points into consideration, I may safely assert that the list given below will be found to contain the cream of all the cultivated varieties, *i.e.*, as far as constant and free-bearing qualities and hardiness of constitution are concerned; and what is of no less moment, good keeping qualities proportionately with their season of ripening. The principle on which I have made my selection of varieties is this:—I have supposed myself compelled to grow only a limited number of kinds, and yet with a minimum of sorts, I am expected to have a maximum supply of Pears, both as to quantity and length of season. Further, I have so arranged my selection that each kind, as in order named, would only be grown by me, supposing I was restricted to one, two, three, or four varieties as the case might be. First on my list I place Winter Nelis, for this I look upon as the Pear of Pears, and therefore if restricted to grow but one variety, this would be that one, and that for several reasons. First, because it is a sure bearer, either on the Quince, or Pear stock, as a standard, an espalier, or on walls, and it is certainly richly deserving of the latter position; secondly, because it ripens more gradually than any other Pear I know, and keeps for a longer season after being fully ripe.—I have known it in continuous use from the middle of October to the end of February; and thirdly, it is of the finest possible quality, being of a rich vinous flavour, with an aroma that never cloy on the palate. My next sort is Bergamotte Espéren, a late Pear, which is not sufficiently well known, or it would be more cultivated; it possesses all the good qualities of Winter Nelis, and to some people, the additional one of having a rich aromatic flavour. Supposing that one had plenty of trees of these two varieties, there would be no difficulty in obtaining a supply of first-class fruit from October to April. Having named two kinds that will assure a long season of dessert fruit, and both sorts rather under average as to size, I next place Duchesse d'Angoulême, in which we get size and quality combined. Moreover, it comes into use frequently by the end of September, and so will lengthen the season considerably, and though it is not usually accepted as a sure bearer, I have but once in ten years known it to fail. Another large variety, and a still earlier ripening kind, though it keeps for some time after it is ripe, is the Bauré d'Amanlis. All points considered, I place this at the head of the list of all early Pears, and for this reason, that it rarely manifests that tendency to premature decay, which such kinds as Jargonelle, Citron des Carmes, Belle de Bruxelles, Williams' Bon Chrétien, and several other early varieties do, most of which are excellent, apart from the short period they remain fit for table. My next variety is Thompson's, perhaps the most delicious, and certainly to my mind the most refreshing, Pear grown; it has none but excellent qualities, and is an immense bearer when grown on the Pear stock. It does very indifferently on the Quince, though, if anything, the fruit is still more excellent when grown on that stock. I next place Marie Louise, a variety too well known to need any comment; and the only reason for its not being placed higher in the list is, that it is not always a certain bearer, unless confined to walls, a position it well merits. Bauré Superfin is a splendid fruit of good size and flavour, and continues in use for about six weeks during September

and October, and sometimes November. My next is Josephine de Malines, a peculiar but pleasant-flavoured fruit, a certain bearer, and one which comes into use at a time when fruit is scarce, *viz.*, from February to April. Next is Glou Moreeau, one of the largest late Pears, which has but one fault, and that is its uncertain period of ripening; I have known it ripe as early as October and as late as March. Generally it is at its best about the beginning of the New Year. Passe Colmar is a kind highly valued here, not only for its qualities for dessert, but for its great productiveness. It also keeps in good condition for a long time after it is fit for table, a quality of no small importance. My next is Knight's Monarch, which has no rival for delicate flavour and perfume; it, too, keeps a long time after being ripe; its season is from the end of December to February, but here this season we have had it in use for two months past, and I am inclined to attribute its premature ripening to the excessively hot weather of the past summer. Ne Plus Meuris is the largest late Pear that has yet come under my observation; sometimes the flesh is a little gritty, but for a late Pear it may be said to be of the first order, and never fails to bear a full crop either on standards or walls; and so I might go on and name dozens of other varieties, all in their way excellent, but as my doing so would only add to the perplexity of those seeking a selection of really good kinds, the above will be sufficient. W. WILDSMITH.

Hockfield.

HARDY PLANTS IN FLOWER IN LONDON GARDENS.

THE unusually mild weather which we have lately experienced has been the means of bringing into flower many plants which naturally bloom later in the season, and which would, if clear, sunny weather prevailed, be very attractive, but the heavy and continuous rains which we have had have rendered them somewhat colourless and of shorter duration than they otherwise would have been. Iris stylosa is producing its lilac-coloured flowers in abundance in the Fulham nurseries, where Narcissus papyraceus may also be found in good condition. In Mr. Barr's grounds at Tooting the winter Heliotrope (*Pussilago fragrans*) is very beautiful, as is also the Crimean Snowdrop (*Galanthus plicatus*); *Galanthus Imperati*, too, is producing its large white flowers in great numbers. This Snowdrop, on account of the size of its blossoms, and their adaptability for button-hole bouquets, is well worth extensive cultivation. The purple-flowered Grape Hyacinth is also very pretty just now, as are likewise many plants of *Cyclamen Atkinsi*. The spring Star-flowers (*Triteleia uniflora* and *T. alliacea*) are making a good display in Ware's nursery at Tottenham; the latter especially has been producing quantities of flowers for many weeks past. There are also in bloom at Tottenham many species of Crocuses, Iberis, and Christmas Roses, and the Rosy Rock Cress (*Arabis blepharophylla*) is flowering abundantly in raised beds and in deep, sandy, well-drained loam. The Cape Pondweed still continues to produce its fragrant blossoms in profusion, a condition in which it will probably be found for some weeks to come should severe weather not set in. S.

HOUSE-TOP GARDENS.—Dr. Richardson, in a lecture on sanatory matters, delivered the other day at the London Institution, spoke as follows concerning these:—At the top of the house I would have, on a firm, almost level, asphalted roof, a brick and glass-covered garden, equal in extent to the area of the house. Into this the stair-shaft would finally enter, and any emanations from the lower part of the house would be eaten up wholesomely by the living vegetation. Heated readily from the kitchen, which should be on the third floor, this garden might have at all times a summer temperature, in which children could engage in luxurious and healthful play; ladies would find occupation in it, in the cultivation of flowers and evergreens, and in it the sterner sex might spend those hours which were now found so unspeakably dull, owing to the monotony of one or two rooms. In this garden, with the pleasant, the natural, and the beautiful, health would be trained, and happiness, her dependent sister, nourished.

NOTES OF THE WEEK.

COTONEASTER AFFINIS.—Among the best red berry-bearing plants must be ranked this Cotoneaster. We have a plant of it here about 20 ft. high, branches of which are every year at this time loaded with berries. I have this year used it, stripped of its leaves, for church decoration among the Holly instead of Holly berries. Our plant of it is always much admired by visitors, very few of whom seem to know what it is. It grows freely and deserves more attention than it receives.—JOHN GARLAND, *Killerton, Evesham*.

THE NEW WHITE HYDRANGEA.—This will be found to be one of the most useful of easily-cultivated market or conservatory plants. I saw it in 60 and 48-sized pots at Mr. John Cadnepes, of Flushing, Long Island, New York, where its large heads of pure white flowers were very beautiful. It also does well in the open border. Its flower-heads are quite as large as those of *H. hortensis*, and the plant appears to be in every way equally accommodating.—W. HOWARD, 29, *King Street, Covent Garden*.

PLANTS IN FLOWER ON NEW YEAR'S DAY AT PRESTON, CIRENCESTER.—In greenhouses—*Clivia nobilis*, *Amaryllis pardina*, A. sp. *Bolivia*, *Scilla natalensis* (a lovely spike of flowers 2 ft. high), *Hemanthus natalensis*, *Lachenalia orchoides* (?), *Veltheimia viridifolia* (a beautiful plant which is too little known). In frames and open ground—*Xiphion Histrio*, *Hessea spiralis*, *Crocus yraiensis*, C. *Fleischeri*, C. *Bryi*, C. *Orphanesii*, C. *Tourneforti*, C. *Imperati*, C. sp. *nova*, *Colchicum Bisignani*, *Galanthus plicatus*, and G. *Elwesi* (the two last named in bud).—H. J. ELWEN.

THE CEANOTHUS AS A WINTER FLOWER.—Those who have to provide cut flowers, either for small or large establishments, will find *Ceanothus azureus grandiflorus* most useful for that purpose. Flowering as it does at the ends of the young growths, it can be cut any length required, and its beautiful blue colour associates well with flowers of other tints. I have found it quite hardy, and have cut blooms of it from a plant growing here on a south-west wall from September to Christmas.—JOHN GOUGH, *Westwood Park, Drogheda*.

PERPETUAL-BLOOMING PELARGONIUM.—I can strongly recommend *La Grande* as a good winter and perpetual-blooming *Pelargonium*. I have had one now for upwards of two years grown as a standard in an 8-in. pot on my conservatory border, and it has never been out of flower the whole time. There are now upwards of a dozen fine blooms on it. It roots into the border, and every now and then I raise it to break the roots. I think in this and in its being grown as a standard lies the secret of my success.—L. T. B.

A WINTER-FLOWERING HONEYSUCKLE.—We have received from the Rev. Mr. Evbank cut specimens of *Lonicera fragrantissima*, which is now beautifully in flower in his garden in the Isle of Wight, and as sweet-scented as a Violet. It is one of the most useful of Honeysuckles, and one which, on account of its hardiness and fragrance, should find a place in every garden.

FLOWERS IN BLOOM OUT-OF-DOORS IN DORSET.—Among these may be mentioned Violets (The Czar, double Russian, and Neapolitan), Pansies, Wallflowers, Intermediate Stocks, Yellow Primroses, Polyanthuses, *Iberis sempervirens*, and Christmas Roses. In spite of the mild weather, however, growth is not so forward as one might have expected. Probably the excessive wet renders the ground cold and keeps it in check.—W. E., *Dorchester*.

LORD BURGHLEY APPLE.—Those of your readers who are planting Apple trees would do well to plant a few trees of this variety. Judging from some young pyramids planted here three years ago, it is a free-fruited kind. They bore fruit during the past summer when several other varieties planted at the same time and under similar circumstances entirely failed. It is a late dessert Apple of good size and appearance, and excellent in flavour.—H. J. C., *Grimston*.

PHALANOPSIS PORTEI IN BLOOM.—Probably the finest plant in the country of this lovely Orchid is now flowering freely in Lord Londesborough's collection at Norbiton. It is bearing three or four good spikes of large, beautifully-tinted blossoms. When better known this will probably be as great a favourite as any of the species belonging to this well-known genus.—M.

HABROHAMNUS ELEGANS FRUITING IN WINTER.—This vigorous Solanaceous plant will doubtless be familiar to many of your readers as a gracefully branching plant admirably adapted for training up the pillars of a conservatory, in which when planted out in a good border, it will keep up a succession of bloom nearly all the year round; but it is its fruiting condition to which I wish now to direct attention. When at Glasnevin a short time ago, I was much struck with its clusters of fruit some 6 in. or more in length hanging from the tips of the shoots. The bunches are oval in shape, and the individual berries about the size of Grapes that have just "set." Their

chief attraction hinges on their colour, which is a rich, rosy-carmine, varying a little in depth of tint according to the age and development of the berries. While some branches bore the rich-looking berries I have just described, others were in full blossom, but the flowers were very inferior as regards beauty compared with the berries. It was growing in a cool greenhouse where, being a Mexican plant, it is perfectly at home. If grown as it sometimes is under the continuously exciting influence of a stove, it is neither so free-blooming nor does it produce berries.—J. C. NIVEN, *Botanic Garden, Hull*.

SOPHRONITIS VIOLACEA.—Several plants of this pretty little Orchid are now very attractive in one of the houses in Lord Londesborough's garden at Norbiton. They are growing in small wooden baskets suspended from the roof, each plant being furnished with from twenty to thirty rich violet-coloured blossoms.—C.

OUT-DOOR VEGETATION IN SUFFOLK.—I have just gathered a *Gloire de Dijon* Rose fully expanded on an open wall. The common Primrose is in full bloom in sheltered spots, and bulbs of all kinds are at least a month in advance of ordinary seasons. Fruit-buds are swelling fast, and unless colder weather sets in soon the prospects of a fruit crop will be very uncertain.—J. GROOM, *Henham*.

BIGNONIA VENUSTA AT SYON.—This old-fashioned Bignonia is now finely in flower in one of the houses at Syon, where it grows in an inside border, its shoots being trained under the roof. From these the blossoms hang down in graceful profusion, and quite enliven the house with their bright colours. Few winter-flowering climbing plants are of greater value than this, or are greater favourites with bouquet makers.

ODONTOGLOSSUM CIRRHOSUM.—A fine plant of this new and rare *Odontoglossum*, in Lord Londesborough's collection at Norbiton, is now producing several very large and unusually strong flower-spikes, thickly set with buds, many of which are beginning to open. This is by far the finest plant of the kind which I have yet seen in flower.—S.

RAINFALL AT WELBECK IN 1876.—The amount of rainfall here in 1876 is 32.14 in., being about 7 in. above the average fall for the last thirty years as registered here. There have been several years with a larger rainfall, but few in which it has been so irregularly distributed. April, May, July, and August were very dry months, and September, October, December, and January quite the reverse. In December the rainfall here was 6.05 in., and if that be added which has fallen in January up to this date, the amount is 8½ in. This large quantity has quite flooded all the low-lying lands, and great injury has been done to the crops of winter Wheat where they have been covered with the water.—WILLIAM TILLERY, *Welbeck*.

ORCHIDS IN FLOWER AT MR. DAY'S.—The Orchid-houses of Mr. Day at Tottenham are, even during this wet, sunless season, wonderfully attractive, many of the plants being unusually well-flowered. Amongst these may be named *Laelia anceps*, which is furnished with nine or ten strong spikes thickly studded with large, delicately tinted blossoms. *Cypripedium Roezli* is in equally good condition, many of its flower-spikes being from 3 ft. to 4 ft. in height, and some of them branching from the sides, rather an unusual occurrence. *Odontoglossum cirrhosum* is also flowering freely here, one spike just going out of bloom having borne eleven large and prettily marked blossoms. *Laelia pumila* and *Dayana* (the latter as yet a scarce plant) are both finely in bloom, as are also several kinds of *Phalenopsis*; these latter are producing flower-spikes of a size and strength rarely seen, *P. Portei* being especially well flowered for the size of the plant; many others of the better known kinds of Orchids are also finely in blossom here, and foremost amongst these may be named specimens of *Phaius Wallichi*, which are bearing eight or nine flower-spikes, each exhibiting unusual strength. In short, all the plants grown here indicate excellent cultivation.—S.

PROPOSED SHOW OF CARNATIONS AND PICOTEES.—The undersigned desire to state that, in consequence of the uncertainty as to the action of the Royal Horticultural Society, they intend to promote a show of Carnations and Picotees to be held in London during the season (July), and they will be glad of the co-operation of other florists in the work. A meeting to arrange preliminaries and commence a subscription for the prize fund will be held at the rooms of the Horticultural Club, 4, Adelphi Terrace, Strand, on Wednesday, January 31st, at two o'clock, when the attendance of all interested will be greatly esteemed.—CHARLES TURNER, *Royal Nursery, Slough*; JAMES DOUGLAS, *Lorford Hall*; E. S. DODWELL, *Larkhall Rise, Clapham*.

THE ALBUM BENARY.—M. Benary, of Erfurt, sends us a copy of the above, in which a great variety of vegetables is exceedingly well illustrated in colours. We shall probably refer to it again.

CHRISTMAS-FLOWERING ROSES.

WE have at least two Roses commonly grown in our gardens from which in mild seasons we can expect to gather delicately-tinted buds or flowers during the last week in the year. In this respect the old Monthly Rose or Common China rarely disappoints us in mild seasons, if planted in a sheltered position where it can obtain its full share of sunshine. The other variety—Gloire de Dijon—is, without doubt, the most floriferous of all Roses now cultivated in our gardens; it is the first to open its salmon or rosy-tinted buds in May, and after blooming at intervals throughout the summer, its flowers still linger until late in the year, unless indeed we have unusually rough weather. The annexed sketch represents the gable end of a cottage in Burntwood Lane, Upper Tooting, where in December last a dozen at least of good flowers of this last-named variety might have been gathered fresh and beautiful, and with foliage not often seen so perfect so late in the season. The whole secret as regards this extremely late blooming may be included in the two words sunshine and shelter, since not only is the Rose tree itself protected from cold rains by the overhauling weather-boarding, but on either side the violence of the wintry gales is broken by a Holly bush on the one side and a Yew tree on the other.

A propos of the present scarcity of Holly berries, I may say that the particular Holly tree here alluded to bears a very fair crop of its coral-coloured fruit nestling amongst the glossiest of leaves. Outdoor Roses at Christmas are not commonly met with even so far north as London, but I gather from what I have seen in the case just described that by planting Gloire de Dijon and the common monthly varieties on sunny walls, and giving them the protection of a broad projecting coping, and perchance that of a mat in very severe weather, those who do not possess a glass house need not despair of gathering a few fresh and fragrant Rose buds much later in the year than is generally the case at present.

F. W. B.

A Christmas-flowering Rose (Gloire de Dijon).

Wallflowers in Market Gardens.

—These are looking extremely well in spite of the long-continued rains which we have had. With early-planted breadths flowering has been fairly abundant for some time, so that cutting has been carried on more or less all through the winter. Should the present mild weather continue, Wallflowers will be in full bloom during February and March, as the plants are now full of buds at every point. This precocity is the result of early sowing and planting, practices that are well repaid by the occurrence of bloom so much earlier in the year than it otherwise would be.—A. D.

Berry-bearing Plants for Winter Decoration.—I felt disappointed in the remarks by "A." on this subject (see p. 18) that the Pyracantha was omitted. If any plant is to take the place of the Holly as a red-berried plant, it must be the Pyracantha; the quantity of berries produced by this plant is enormous when allowed to grow, as it will grow over a very large space. There is a gentleman's house, not far from here, the front of which is completely covered with this plant, and bunches of its brilliant berries may be gathered by the thousand. Will "A." kindly inform me which of the Cotoneasters is meant by the one alluded to whose berries "glow on the wall like masses of pearls?" I have often thought they looked like coral, but never heard of one whose fruit was like pearls. Cotoneaster Simmondsi is a truly handsome plant when in berry, and perhaps that is the only time in which it is truly handsome. When the prejudice for red-berried Holly has given way, plenty of beautiful berry-bearing shrubs are ready to take its place. What charming plants the Pernettias are for this purpose, literally loaded with berries of every shade, from purple to pure white! And why should not the Snowberry be used for winter decoration? Its slender

branches loaded with snow-white fruit thrust in here and there among evergreens, or in wreaths, would be simply charming, and a vaseful of the common-berried Holly mingled with the berries of the golden variety is a sight long to be remembered.—THOS. WILLIAMS, Ormskirk.

A White Germander Speedwell.—Permit me to add a word or two to my article on the Speedwells (see p. 611, Vol. X.). Mr. Moly, of Hawkchurch, informs me that he has found a white variety of the Germander Speedwell in Devonshire, a fact which I have all the more pleasure in communicating, seeing that he has promised me a plant of it. I have often wondered, considering how liable the various species of Veronicas are to sport from blue to white, that I had never met with a Germander Speedwell in any other garb than that of blue, nor indeed have I ever heard of such an occurrence before; hence Mr. Moly's discovery is all the more worthy of record. Anderson's Speedwell (*Veronica Andersoni*), not mentioned in my list as being one of the many hybrids which the shrubby section has produced, gave me a great surprise the other day when in Ireland, where, on the south side of Killiney Hill, it was used in the form of diagonal hedges to shelter a kitchen garden which sloped in a very precipitous manner to the very edge of the cliff overhanging the sea. Here it formed a series of continuous lines rich in fresh green foliage, and literally covered with dense spikes of purplish-blue flowers. It formed such a picture as few other plants can present in the dreary month of December, and is notably one of the very best sea-side plants we have.—J. C. NIVEN, *Botanic Garden, Hull.*

Primroses in January.—These are blooming freely in the open air, the rainfall in September having assisted to promote the formation of good foliage and strong crowns. At a time when flower gardens have little that is strictly floral in them, a few patches of coloured Primroses are not without interest. Well-established plants as a rule flower earliest, the vigorous root power possessed promoting the formation of strong crowns. Where choice kinds are scorched by the summer's sun, pieces of Fir spray or other shading material should be placed round them, as the loss of foliage is the greatest evil that can befall the plants. A moderate top-dressing of rotten manure will also prove most helpful.—D.

Bolander's Catchfly.—Mr. Niven's remarks in his paper on the Catchflies in regard to this plant are in accordance with my own observations. I had some dozens of patches of it this summer, and it appeared to be absolutely leafless—in this respect it is similar to *S. flava*, a singular species, with yellow flowers, but no beauty. *S. Bolanderi* may have a charm of its own as a species, but it appears too weedy for decorative purposes. It may however look well in a mass, as we sometimes see *Saponaria calabrica*. Like Mr. Niven I have never seen the true *S. regia*, as the plant purporting to be it from different sources, has always proved to be a weed. And now allow me to point out what is evidently an error; the woodcut illustration on page 11 of *S. Saxifraga* cannot represent that plant. The remarks respecting it are perfectly correct, but the figure given must belong to some other species. The petals of *S. Saxifraga* are so deeply cut as to be truly stellate, so much so that the plant appears to have ten petals instead of five.—THOS. WILLIAMS, Ormskirk.

Convolvulus major in Autumn.—Last October this stood conspicuously among the many flowers that the mild autumn weather induced to bloom. It was sown in February very thinly in rows, stuck like Sweet Peas, and when loaded with blossoms was strikingly effective. It is a plant that seems to suit all seasons, neither drought nor excessive moisture apparently affecting its growth, and it keeps in beauty as long as any annual that is used for the decoration of our gardens.—J. G.

Violas in Mixed Beds.—A general impression exists that Violas are not satisfactory in dry seasons and situations, but during last summer, which was exceptionally hot and dry, some beds of *Viola Perfecta* and *Polygonum variegatum* were very effective and continuous. By employing a combination of flowering and fine-foliaged plants for mixed beds, one may confidently rely on having good results in all seasons, whether wet or dry. Most of the Violas possessing various shades of purple flowers form effective contrasts with dwarf variegated plants, such as variegated *Alyssum* or *Lady Plymouth Felargonium*. —JAMES GROOM, *Henham.*

THE GARDEN IN THE HOUSE.

WATER BOUQUETS.

THESE are ordinary bouquets preserved in water from which the air is excluded, and which keep fresh and beautiful for periods of a week or a fortnight, or even three weeks, according to the character of the flowers or foliage used, the care with which they are made, and the purity of the water employed. Water bouquets, formed chiefly of Ferns and other foliage, such as Crotons for example, so rich in colouring, and so diverse in form, may be preserved in perfection for a month or more. The beauty of each leaf and sprig is also displayed to the utmost perfection in water bouquets. There is no huddling of the flowers or foliage into masses, on the contrary, each branchlet, leaf, or flower may be allowed to float gracefully in the water while seen throughout its entire length in all its natural beauty. This extreme grace and lightness form one of the chief charms of water bouquets. But, it may be asked, how are they made? Thus:—Take a shell, a piece of coral, a flint, or other stone, or bit of metal—the two first are the best—and construct a bouquet of any handy size upon or around it, securing, however, all the materials of the bouquet to whichever one of these substances may be used. The weight of the coral, shell, or stone, should be sufficient to hold the bouquet in one position in the water; if coral be used, it adds to the beauty of the bouquet to allow part of it to be seen through and among the flowers; if stones or other weights be employed, they may readily be hidden with the flowers or foliage of the bouquet. A piece of lead drilled full of holes to allow the bouquet wires to be passed through them, forms a handy base for water bouquets. It is easy to place each flower and leaf exactly where the eye of cultured taste may direct in such a base so as to form bouquets of any desired character, colour, or size. Every part of the bouquet and its base must be perfectly clean; no Moss or other material that would cause the slightest sediment must be used in its formation or arrangement. If any dust or dirt adhere to leaf or flower it should be washed off, either before or immediately after making.

Having finished the arrangement of the flowers, three things are needful for the completion and display of the water bouquet: these are—a bell-glass, or glass shade without a knob, a china or other plate or dish with a flat, even surface, and of course waterproof, and a tub or pailful of clean water. Glass, shade, dish, and water, must all be thoroughly clean; the pail or tub must be sufficiently large to allow the bouquet, glass, or other dish, and bell-glass, to be all submerged in water together. With bouquets of any size, the simplest mode of proceeding is to bare the arms beyond the elbow, place the dish in the tub, set the bouquet carefully in the centre of it, and, holding it in position with one hand, place the glass shade in the water with the other sideways and deep enough till it is perfectly full of water, then turn it over the bouquet and on to the dish without emptying it of water, or exposing any portion of the glass to the air; if properly done, there will be no air bubbles or empty space at the top of the glass; should there be any, the glass must be turned back again, re-filled with water, and turned over again till it is entirely filled with water. There can, however, be no difficulty if the tub or pail be large and deep enough to admit of the whole process of placing and covering the bouquet being accomplished under water. The dish must then be grasped firmly on each side, and lifted out of the water, pouring a little of it from the outside rim of the dish in taking it out, so that it may be carried easily anywhere without spilling any, which it would be difficult to prevent were the lip of the dish beyond the globe full to the brim. The inexperienced, however, had better use a sponge for this purpose, as the change of level necessary to get rid of this outside water is apt to let out some from the inside also and to let in the air, which spoils the effect. A little water should also be left outside the bell-glass, as it tends to make the union between the glass and its base more secure. Dish and glass should then be wiped dry, and the bouquet placed on a drawing or sitting room table. The whole bouquet floats in the water above the level of the dish, and the effect, if everything be perfectly clean, is most pleasing. The air in the leaves and flowers comes

out and remains like crystals on their surface, and almost every sort of flower and leaf too, seems to vary in the amount of air expired by them. These aerial crystals form rapidly during the first hour or two, continue bright and beautiful for several days, and then many of them seem to collapse in the water. Bouquets of this kind must, of course, be handled and moved with care, and the dish on which they stand must be held nearly level. Those to whom their management is entrusted must be cautioned not to hold them on one side in dusting, or not only will the water come out with a rush, but the glasses will often break into fragments with the pressure of the atmosphere upon the internal vacuum caused by the loss of the water. Of course it will be understood that in such bouquets the water is kept in the glass by atmospheric pressure, and that being the case it will be obvious that the air outside would support a column of water under the conditions described as high or higher than the ceilings of most sitting-rooms, therefore glasses of any size may be used with safety. In renewing such bouquets some care is necessary. The only safe course, in fact, is exactly the same as that pointed out for enclosing them in the glasses. Remove dish, glass, and bouquet just as they stand, plunge them overhead in water, and the whole will fall asunder. To the careful observer the bouquet and water alike give obvious notice of time for removal. When the flowers lose their brightness, and the water becomes a little cloudy, the bouquet should at once be removed. Glass, dish, and weight must all be scrupulously cleaned, and a new bouquet made and placed in position, as already pointed out. The lasting qualities of such bouquets are not wholly owing to their submersion. They also escape all gas and fire-dried air, and enjoy a much more uniform temperature than they would do under other conditions. They likewise admit of the use of flowers that may be injurious or disagreeable to many from their excess of sweetness or of disagreeable odour. For example, many have a positive dislike to the odour of Chrysanthemums; these, especially the Japanese ones, with their long, thread-like petals, are among the most interesting flowers for water bouquets. Paneratiums, again, Eucharis, Nymphaeas, and other Liliaceous plants are excellent for the purpose, as are also Narcissi, Hyacinths, and Snowdrops. Many of the Begonias and Moss Rose buds are remarkably beautiful in water bouquets. But any or all flowers may be tried; and those who have few or no flowers may make chaste and pleasing water bouquets with nothing but leaves and berries, such as Mosses, Ferns, Grasses, Holly, Retinosporas, or even Hips, Haws, and Ivy leaves. Water bouquets would be useful in smoky towns and crowded dwellings, where flowers droop and fade almost as soon as they enter them. Constant complaints are made that cut flowers sent to Loudon and other large towns droop and die on their arrival. A few at least of these may easily be preserved in water bouquets for several weeks.

D. T. FISHER.

WINDOW PLANTS.

WINDOWS filled with healthy Scarlet Pelargoniums, Fuchsias, Saxifrages, and similar plants, always convey a sense of refreshing coolness to a room during hot weather, and even in winter window gardening well repays any little extra attention that may be bestowed upon it. It is indeed gratifying to witness the progress which this branch of cultivation has made of late years, and its beautifying effect upon the dwellings of our cottagers and artisans. Drawbacks I have certainly frequently noticed, but with a little care these may be overcome. First, as regards potting. A plant should never be put into a dirty pot; on the contrary, all pots should be thoroughly washed, and not used until they are quite dry, otherwise in shifting, the ball sticks and the roots get mutilated. In the matter of drainage, the greatest care is necessary, as it is one of the chief points with respect to successful cultivation; and again, in watering window plants much care is likewise necessary, particularly in winter. When they are growing freely, however, they must be well supplied with water, for if the soil be allowed to get too dry, the roots cannot obtain the amount of moisture which is required. On the other hand, to deluge them with water is equally a mistake. Enough should be given to thoroughly penetrate the soil and no more. I have

frequently noticed the plan of placing pots of window plants in pans and saucers adopted. It is, however, a bad system, inasmuch as it impairs the efficiency of the drainage, consequently the soil in time turns sour, the leaves become yellow, and the plants themselves fall into bad health. Some plants require more water than others, and therefore should be watered oftener. Among these may be named the White Arum Lily, Common Toadflax, Creeping Jenny, Musk, *Spiræa japonica*, Oleander, and many kinds of bulbs—plants which will even succeed with saucers under them. Another drawback to successful cultivation is the prevalence of painted pots, a condition which destroys their porosity. All window plants should be in porous pots, and in order to secure this let them be kept scrupulously clean. Window plants should have as much light as possible and plenty of air, and they should not be too much crowded. It will likewise be found advantageous to expose them often to mild, gentle showers, which will have a tendency to regenerate them, and to clear the foliage of dust and other impurities. When potting, the soil should be used in a medium state as to dryness. If it be too wet, it becomes hard and almost air-tight, and under such circumstances no plant will keep long in health. Potting and pruning should not be performed at the same time. Plants such as Fuchsias, for instance, ought not to be potted until they have slightly started into growth. Any pruning which they may need should be done first, and just when the buds have begun to break into growth, the roots may be considered in a fit state to be benefited by a shift into fresh soil. For window boxes ornamental-foliated plants should be mixed with flowering ones, such as *Duc Van Thol* and other early Tulips, Hyacinths, and Crocuses. Beyond these it is almost needless to name the kinds of plants best adapted for window culture, but in addition to *Pelargoniums*, *Fuchsias*, *Calla æthiopica*, and *Myrtles*, I would have *Cannas*, *Solanums*, *Chrysanthemums*, *Hydrangeas*, *Ferns*, *Saxifrages*, *Stocks*, *Mignonette*, *Caladiums*, red-leaved *Dracænas*, *Cactuses*, *Petunias*, and *Amaryllises*. JOHN BOYD.

Balbriggan, Co. Dublin.

Honesty Pods as Winter Ornaments.—Few subjects useful for winter house decoration are more easy to be obtained by every one than the seed-pods of the Common *Honesty*. The note (see p. 2) respecting them induces me to mention that *Honesty* is so easily raised from seed in spring, and is so very showy through the month of April, that it deserves a place in every garden. When dressing the pods to obtain the seed, the branches are simply thrashed out without regard to the pods, but where these latter are required for indoor decoration, the pods should be taken between the forefinger and thumb singly and gently rubbed; the outer scales then fall off, leaving the inner and almost transparent division intact. It is better to do this patiently than to thrash or otherwise roughly knock the seeds out. The white-flowered variety produces the best pieces, and only those seed branches should be selected that are thoroughly robust and well-ripened.—D.

The Christmas Rose.—Walking recently along the Hounslow Road I was much struck with the beauty of several fine plants of this charming white *Hellebore*, covered with large clusters of flowers. How correctly this hardy plant is named was truly exemplified, for these were in full bloom on Christmas Day and through the most dismal period of the year. Looking at the scarcity of white flowers in midwinter, it may be worthy of consideration whether it would not pay to protect these clumps of bloom by means of large bell-glasses, supported by thin bricks or tiles to admit the air, and yet exclude the rain. The purity of the blooms would be much enhanced by this slight protection, and if somewhat drawn, they would be none the worse if wanted in a cut state. The Christmas Rose dislikes frequent removal, and therefore the lifting of strong plants of it annually into frames or houses would not answer, whilst bell-glasses would afford protection, and be serviceable in other ways.—A.

Long-stalked Violets Best.—These have hardly received the attention which they deserve. Such Violets as *The Czar* and, in a lesser degree, *Victoria Regina*, are invaluable for bouquet purposes or for vases, on account of the length of their stalks, which are long enough to reach the water or to be worked up into bouquets without mounting, and hence their greater longevity and increased adaptability for bouquet purposes. Both have been exceptionally plentiful and fine this autumn and winter. *The Victoria Regina* is our favourite, though *The Czar* is also a noble Violet, very sweet, and with the longest stalk of any.—D. T. FISH.

TREES AND SHRUBS.

CUTTING DOWN LARGE EVERGREENS.

THE freedom with which healthy Laurel bushes break and grow again when cut down is well known to those who have experience with shrubberies, and cultivators are in the habit of cutting such subjects down without hesitation, when occasions arise for so doing; but with very old trees stubbing-up and re-planting is sometimes recommended in preference to cutting down and trusting to the old stumps to form a cover again. I venture to say, however, that unless the trees are very old and feeble indeed, nay, almost dead, they may be cut down with impunity, and without any doubt about their growing again and furnishing freely, in fact, they make large bushes sooner than young plants do. Many a scraggy, old bush I have seen left standing because the proprietor did not wish to do away with it, and was afraid to use the saw. I have operated on many such during the last ten years without any mishaps, and strangers to see the trees now would imagine they were quite young. They are mostly Portugal Laurels from fifty to seventy years of age, and, before they were cut down, standing 30 ft. or 40 ft. high, and as much and more in the spread of the branches, with stems 3 ft. or 4 ft. in circumference. All of them were dying off at their tops year by year, and the living branches made scarcely any growth, but they flowered and seeded with the utmost freedom, a sure sign of old age and debility with the Laurel in the north, where young and vigorous trees never flower as they do in the south of England. Well, we cut them all over, 2 ft. from the ground or so, and found that the old limbs were in most cases dead down to the ground inside, there being only a ring of living wood of no great thickness next the bark—in some places, indeed, scarcely anything but the bark itself. Most of the cutting was performed in spring, some of it being done shortly after the new year; but about March or April is the best time, just before growth commences. A few of the bushes in prominent positions had their roots top-dressed with refuse soil, but the greater number of them received no attention in that way. All broke, however, very thickly, and made tolerably good bushes the same season, completely hiding the old stumps. One of the most scraggy specimens growing on the lawn, whose limbs of which were dying off annually, was cut down nearly to the ground where the stem was about 18 in. thick, and top-dressed for 6 ft. or 7 ft. out all round. This tree I measured the other day, and found it was 10 ft. high, 12 ft. through, in robust health, and nearly as round as a cricket ball, though it will only be four years come May next since it was cut down. The vigorous young growth has deposited quite a new layer of wood round the old stump, and has no doubt also induced the formation of fresh roots, making the old tree really young again. It is this deposit of new bark which regenerates the tree to a great extent. The more young growth there is the thicker the annual rings of bark become, and the greater the quantity of roots produced. Another old veteran Portugal Laurel, whose branches were spread far and wide upon the ground, was cut wherever the limbs touched the soil, and they have now sprouted and are like a thicket of healthy young bushes. The Holly is amenable to the same treatment. Old trees cut down throw up perfectly straight shoots, and soon make shapely young trees. We have a number of these here which had at one time been so treated. Our soil, I should state, is extremely thin and poor where the Laurels are growing, which has probably helped to forward their decay. But evergreens are not the only subjects which may be renovated in this way; and, while there is any vigour in the tree, it is never too late to begin remedial measures. One instance is worth recording. Some time ago an ancient Oak tree—probably 1000 years old, for the stem was 7 ft. in diameter several feet from the ground—was pointed out to me that had put on a “growing spurt” during the last fifty years or more, in consequence, it was supposed, of alterations in the configuration of the ground, and the clearing away of other trees around it. The tree previously had been going back, it was thought, and there was a large hole on one side of it where a man could easily enter to the hollow interior—capable of holding several people—but now, owing to the fresh deposit of wood round the

sides of the hole, a boy cannot squeeze through it. The tree has at one time lost limbs through decay, as can easily be seen; but, at present, it is in good health, and makes considerable growth annually.

J. S.

Forest Meteorology.—About three years ago we ("Academy") reviewed Prof. Ebermayer's account of the work of the Bavarian Forest Academy at Aeschaffenburg, and now we have the first report of a similar nature from Prussia from the pen of Dr. A. Müttrich. Ten observing stations have been organised, three being in Alsace and Lorraine, one in the Eifel, and the other six in various parts of Prussia Proper, from Gumbionen to Erfurt. Each establishment consists of two stations, one in the forest and the other in the open ground. The observations comprise the ordinary routine of simple meteorological observations, with special attention to evaporation, and also to the temperature, &c., in the crown of the tree—i.e., at the points where the main branches spring—and we have the tabular monthly results for each station, but without much discussion. It would be a matter of great interest if some of our own large proprietors would establish similar stations on their estates, but we fear that at present such an idea is Utopian. In connection with the same subject of the effects of forests on climate, we may here notice Herr Wojekoff's short paper on the climate of Manitoba, which appeared in the "Austrian Journal" for October 1. He points out in it that the station at Winnipeg, where the observations have been conducted for some years past under the superintendence of the Bishop of Rapert's Land, is admirably fitted to furnish information as to the influence of prairies and forests on climate, inasmuch as the face of the country has hardly yet been materially altered by cultivation. Among other interesting points it may be noticed in that region how, since the disappearance of the bison, the struggle for existence has been carried on between the Grass and the trees, sometimes the one and sometimes the other type of vegetation predominating. The period of observation is, however, far too short as yet to afford results of much value as to climate.

Abies Fraseri.—At a recent meeting of the Academy of Natural Sciences of Philadelphia, Dr. Engelmann, of St. Louis, spoke about *Abies Fraseri*, the very local species of the highest mountains of North Carolina, which he had just visited, together with several botanical friends, members of this Society. This is the tree which caused these mountains to be designated the Black Mountains, giving their summits that sombre hue for which they are known; they seem to grow nowhere but on these mountains, and only on those that reach up to or above 6000 ft. altitude. The northern localities claimed for the species rest on confusion with forms of *Abies balsamea*, the common northern Balsam, of which our tree may be claimed to be the southern representative. *A. balsamea* does not seem to extend southward further than the Virginia mountain region, and it would be interesting to ascertain how near both species approach each other. Besides the well-known characters of the cones and their cusps, excellent distinctions are found in the structure of the leaves of both species. It may not be generally known, though it is a fact to which, since several years, some European botanists have called attention, that the anatomical structure of the leaves of these species, as well as of Conifers in general, is extremely various, and that this structure well characterizes many species, and is one of the safest means to arrange them in natural groups. *Abies Fraseri* and *balsamea* are so nearly allied that without fruit they are constantly confounded, but the structure of the leaves will always distinguish them so well that a single leaf, or even a fragment of one, will invariably solve all difficulty. The leaves of *Abies* have under the epidermis, and between it and the cells of the parenchyma, which are full of chlorophyll, an arrangement of cells of thick walls, elongate form, and destitute of chlorophyll, analogous to bast cells, which have been called hypodermic cells; we find them in all species of *Abies* on the edges and on the keel, where they strengthen the leaf, but their distribution under the epidermis of the upper side of the leaf is very different in different species—they may be wanting there altogether, or may be differently grouped, or may extend over the whole upper surface; now in all forms of *A. balsamea* they are there almost entirely absent, even in those of the highest New England mountains, while *A. Fraseri* exhibits under the microscope a continuous hypodermic stratum of them.

The Spindle Tree.—Mr. McNab complains, and with justice, of the scarcity of Holly berries this year. There never was, however, a more plentiful supply of the beautiful coral-like fruit of the Spindle Tree (*Euonymus europæus*). It is not by any means a common shrub, nor so often seen as its undoubted merits deserve, although a British plant. It establishes itself in woods readily, and its berries form a favourite food for pheasants and other birds.—SALMONICERS.

THE LIBRARY.

"WHITE'S SELBORNE." *

WHAT interests us most in this book are the pictures of Gilbert White's house and garden which show the true English garden and the garden on the house, a feature not often seen out of England. These peeps at an old English cottage are refreshing to eyes wearied with the miserable parallelograms and other puerilities of the modern garden. In these days of besom drawing and hatchet engraving, it is pleasant to see evidence in this book that the invaluable and still unrivalled art of good wood engraving is yet extant among us. Mr. Delamotte's drawings are charming, and for the most part well engraved. In a passage written in the year 1778, one is reminded of the recent date of some improvements often thought of long standing. On p. 285 we read:—

As to the produce of a garden, every middle-aged person of observation may perceive, within his own memory, both in town or country, how vastly the consumption of vegetables is increased. Green-stalls in cities now support multitudes in a comfortable state, whilst gardeners get fortunes. Every decent labourer has his garden, which is half support, as well as his delight; and common farmers provide plenty of Beans, Peas, and Greens, for their hinds to eat with their bacon; and those few that do not are despised for their sordid parsimony, and looked upon as regardless of the welfare of their dependants. Potatoes have prevailed in this little district by means of premiums, within these twenty years only; and are much esteemed here now by the poor, who would scarce have ventured to taste them in the last reign.

Our Saxon ancestors certainly had some sort of Cabbage, because they call the month of February sprout-cale; but, long after their days, the cultivation of gardens was little attended to. The religious, being men of leisure, and keeping up a constant correspondence with Italy, were the first people among us that had gardens and fruit trees in any perfection, within the walls of their abbeys, priories, and monasteries, where the lamp of knowledge continued to burn, however dimly. In them men of business were formed for the State; the art of writing was cultivated by the monks; they were the only proficient in mechanics, gardening, and architecture. The barons neglected every pursuit that did not lead to war or tend to the pleasure of the chase.

It was not till gentlemen took up the study of horticulture themselves that the knowledge of gardening made such hasty advances. Lord Cobham, Lord Ilia, and Mr. Waller of Beaconsfield, were some of the first people of rank that promoted the elegant science of ornamenting without despising the superintendence of the kitchen quarters and fruit walls.

A remark made by the excellent Mr. Ray in his "Tour of Europe" at once surprises us, and corroborates what has been advanced above: for we find him observing, so late as his days, that "the Italians use several herbs for sallets, which are not yet or have not been but lately used in England, viz., *Selleri* (Celery), which is nothing else but the Sweet Smallage; the young shoots whereof, with a little of the head of the root cut off, they eat raw with oil and pepper." And farther he adds, "curled Endive blanched is much used beyond seas; and, for a raw sallet, seemed to excel Lettuce itself." Now this journey was undertaken no longer ago than in the year 1663.

This beautiful edition of a famous book is published by Messrs. Macmillan, who have spared no expense in making it a well illustrated and well printed one.

Poetry for Children.—The little volume now before us is the most recent addition to the familiar "Golden Treasury" series, of which Messrs. Macmillan are the publishers, and in which are comprised the gems, not only of English poetry, but of the lyrical Muse of France, Germany, and Scotland. Mr. Palgrave does this kind of work well, and has produced a charming and useful book for children, and one which will also be enjoyed by children of larger growth.

Books on Conifers.—What are the names of the best volumes treating of Conifers?—P. S. [Gordon's "Pinetum" (Bohn), Carrière's "Les Conifers" (Librairie Agricole, Rue Jacob, Paris), and the Monograph in De Candelie's "Prodromus."]

COTTAGE GARDENING.

The Turf-pit.

THIS is a most desirable structure for cultivators on a small scale to possess, and its erection need not involve a very extravagant outlay; in fact, I have known cottage gardeners who have done all the carpenter's work themselves during their spare time, while any one of course can glaze a frame (as glass can be had of any size) and paint the lights when put together. Those living near a large town can generally purchase machine-prepared sash-bars, rails, &c., at a cheap rate, and it will not require a great amount of skill and ingenuity to saw them into lengths and put them together. Those who have means and are ambitious, may construct their pit walls with bricks, but during the last few years brickwork has advanced considerably in price, and there are after considerations that should be borne in mind, even by those who can afford the extra cost. In the first place, a brick pit is not so useful for the purpose of wintering half-hardy plants as a turf-pit; a severe frost will penetrate through a 9-in. wall, but I have never known the same thing to happen with a turf or earth-built wall; and, in the second place, if a tenant had to leave his garden or premises, and could not arrange with the incomer, he could remove everything of any value, level down walls, and the place would be restored to its original condition; but brickwork, unless under a special agreement, becomes the property of the landlord. Altogether, to a man of limited means, a turf-pit would be far cheaper and more useful than a brick-built one. The first thing to be done is to decide upon the size, and then make arrangements for making the lights, which should be of good 2 in. red deal, and the glass should not be of less weight than 21 oz. to the foot, which will be much warmer, and cheaper, too, in the long run, than thin, light, inferior glass; these, however, are details which every one is competent to decide for himself, as also the size so far as regards length, but it should not be too wide, or the lights will be cumbersome to move; the extreme width (inside measure) should not exceed 6 ft., and perhaps in many cases 5 ft. will be considered sufficient. If the pit be erected on a dry site so as to permit of its being sunk from 6 in. to 12 in. in the ground, the earth taken out perhaps may be used in constructing walls if stiff enough to hold together, as there are comparatively few cottagers who could obtain turves with which to build the walls, and neither are they necessary, for earth walls, from containing no fibre or perishable materials, are more permanent than turf. If the earth be sufficiently adhesive to stand when cut to a straight face, which will be necessary for the inside of the pit, to avoid loss of space the outsides had better be cut sloping to throw off wet and to permit of the banks being turfed over, or a thin coat of asphalt may be used instead if preferred. A good coat of limewash, in which a portion of rough sand has been mixed to thicken it, will give the inside a neat, clean appearance, and at the same time tend to keep the earth from crumbling down. The usual arrangement in buildings of this kind is to have the back wall double the height of the front, as this gives a good fall to

carry off the water—always an important consideration in winter in unheated structures, and this of course must be thought of when making the lights so as to have them of sufficient length.

On a very sandy soil, where the walls cannot well be moulded into shape so as to stand alone without inside support, it will be better to line them with builders' slates, which will give the pit a thoroughly strong and neat appearance. Larch poles about 5 in. or 6 in. in diameter sawn into suitable lengths will make capital supports for the framework, and these of course should be let into the ground from 15 in. to 18 in., and have the soil rammed firmly round them. They should be placed 4 ft. apart, so that each pair of posts back and front comes under each rafter; the tops of the posts, when firmly fixed, should be just the height that the walls are intended to be. I have built pits without these posts with the wall-plates simply resting on the earth-walls, but the posts do not add much to the cost, and when the wall-plates are nailed to the tops of the posts, the whole framework is strong and immovable, as if built in brickwork. The posts should stand just flush with the inside, and if it be intended to line the walls with slates to keep the earth from crumbling down, it will be necessary to nail a stout lath to the posts along the

bottom, and another along the top of the slates to take the bearing on the inside; and this should be done first, and then the earth-walls can be built firmly against the slates outside. If the back wall be more than one slate high an extra row of laths will be required. The thickness of the walls may in some measure correspond with their height, and should start with a base considerably broader than their top is intended to be, which will admit of the outside being rounded off and covered with turf. Such a pit will not be unsightly anywhere; and, although in my anxiety to make myself understood, I have been somewhat prolix, yet the actual

work of building after the lights are made is trifling. When the pit is finished, put in the bottom a layer of broken stones, and 2 in. of cinder ashes over them, for the double purpose of keeping out the worms and for drainage. The uses to which a pit of this kind, in the hands of enthusiastic, persevering men, can be put are so numerous, they can only be just glanced at here. Almost all half-hardy plants, with careful management to guard against damp settling on them, may be successfully wintered in such a pit, by having warm coverings for the lights during frosty weather. In February it might be filled with fermenting materials and converted into a hot bed; or, if long enough, a division of rough boards could be made across the centre, and one-half filled with fermenting matter, and the other remain as a cool pit for hardening off plants before being placed in the open air. Stable litter, leaves, tan, sawdust, or spent Hops from a brewery, each and all may be usefully employed in hot-bed making in spring. But where the supply is very limited, it will be better to defer the commencement of propagating and seed-sowing till the middle of March, as then the sun will have more power, and will greatly facilitate the task of keeping the bottom-heat steady. With a pit of this kind 3 ft. deep at back and 18 in. in front, if filled up to within 6 in. or 8 in. of the glass with a mixture

Gilbert White's Garden.

of the materials I have named; or the bottom may be filled in with stable manure with 8 in. or 10 in. of sawdust or any similar material on the tops in which the pots can be plunged. If the stable manure be fresh, it will do no harm, as the depth will not be great and the sawdust will absorb and keep down any destructive gases that may be evolved by fermentation. Of course, as a rule, if large heaps of those substances be used for hotbeds they should first undergo some preliminary mixing and turning to sweeten and drive off some of the rankness, otherwise much mischief may be done. Even Hops, if used in a large bulk and fresh from the brewery, should be used with caution.

On the other hand, when a considerable proportion of leaves or sawdust can be procured and mixed with the more heating substances, the strong heat from the latter will be neutralized and rendered beneficial without much previous trouble. With a hotbed of this kind ready for use about the middle of March, all kinds of seeds that require a little warmth to start them may be sown in pots and plunged in the sawdust close to the glass. A pinch of Celery may be sown and grown on for early work, or a few Cauliflower seeds, if there be any scarcity of early plants; Tomatoes, also, and a few Cucumber seeds of the Telegraph, or some other good kind, should be forwarded for the purpose of planting in the pit when the propagating is pretty well over. All the preparation necessary would be to turn the heating material over, shake it up, mix it well together, put a barrowful of good turfy loam into the middle of each light, and when the warmth of the bed has penetrated it, the Cucumber plants should be turned out, one or two in the centre of each light. Cucumbers would succeed well in such a pit all the summer, and if well looked after, and near a market, they would go a long way towards paying for the pit. After the Cucumbers were over in autumn, the pit could again be filled with plants requiring protection, either vegetables (such as Cauliflowers or Lettuces) or flowering plants that might afterwards be useful in brightening up the windows and rooms of the cottage. And whilst briefly noticing this phase of the subject, what a wide and interesting field here lies open to the possessor of such an adjunct to his garden; by means of it how many beautiful annuals might be started in spring either for window or flower border decoration! Or, if considered only from a utilitarian point of view, what a good use might be made of such a structure for bringing forward Rhubarb, Seakale, early Potatoes, Early Horn Carrots, Radishes, Lettuces, and small salads in early spring! Though all this and much more may be done with only a turf-pit, with the half of it furnishing a hotbed during the spring months, yet it is not advisable, nor indeed is it likely that any one person would attempt so much. Let each one follow his own inclination in the selection of his subjects; but he should only choose a small number, and grow them well. I merely mention a few among the various plants that might be grown in such a place to show the scope there is for individual taste, not with the idea that any one will attempt to do so much in so limited a space. In fact, I may say the greatest evil in the management of small glass structures is attempting too much—forgetting that plants live and breathe, and are as liable to contract disease from overcrowding as human beings are.

E. HOBDDAY.

Veitch's Self-protecting Autumn Broccoli.—I have been cutting this Broccoli from November 26 to the present time (January 6), and now Snow's Winter White and Backhouse's Winter White are just coming in to take its place, thus giving us a continual supply of Broccoli through the winter months. All who have not given Veitch's Autumn Broccoli a trial should do so, for it is a most useful kind.—W. G., *Brighthelm, Dorchester.*

Keeping Potatoes for Two Years.—Allow me to give my experience in this respect with the two varieties, Brownell's Superior and Beauty. I took some tubers and put them in a box and set them on one side in the cellar in October, 1875. Last autumn I found the tubers firm and solid, and cooking them, I found the quality good. In 1871, I (E. S. B., in "Albany Country Gentleman") exhibited in Rochester, at the State Fair, tubers grown in 1873. After the fair was over I put some of the tubers in my valise, and on my return home put them in an open box and set it on a barrel in a common cellar having a sandy bottom. These tubers had been kept the year previous in an open barrel without any extra care, with the cellar windows and door open during the day. The box was open all winter, and the tubers were never moved after they were put in the box. At the end of April, 1875, one of my neighbours called on me, and I brought the tubers out of the cellar. We decided that they would grow, and I planted them in the garden. They did grow, producing a good yield of fine Potatoes. A farmer in this county says that he has some now, grown in 1875, that are in good condition for cooking.

THE INDOOR GARDEN.

CYRTOCERAS REFLEXUM.

This is a handsome, free-flowering plant of moderate growth, very nearly allied to the Hoyas, which in some respects it closely resembles, especially in the general appearance of the flowers, and the short spurs on which they are borne, and that, as in the Hoyas, are persistent, lasting for many years, continuing each season to produce one or more of their white and yellow crops of bloom. The shoots are of a stout, woody nature, erect, and comparatively few in number, springing from the collar of the plant, and not inclined to branch; the leaves are thick and leathery, and of a bright green colour. This plant is well adapted for cultivation by those who have not the convenience of a large stove, as it is a slow grower, and takes a considerable time before it occupies much space; moreover, it bears cutting-in freely when required, breaking up from the bottom if the heading down be performed in the spring. It is indigenous to Manila, and consequently needs to be kept always moderately warm, but when in flower during the summer, it can without injury be moved to a conservatory, but must not be allowed to remain in a draught, although it does not suffer from the drier atmosphere usually maintained like many stove subjects; this can easily be accounted for through the plant never requiring an atmosphere laden with moisture to the extent that many occupants of the stove need; in fact, if the atmosphere in which it is grown be too close and damp, it often has the effect of causing the flowers to fall off before they open; neither does it thrive in so much shade as quicker-growing, thinner-leaved plants demand, if in the hottest weather it be slightly protected from the direct rays of the sun, so as to prevent the leaves being scorched. It strikes freely in the spring from half-ripened cuttings, especially if these consist of side-shoots that can be taken off with a heel; they should be inserted singly in small pots in a mixture of half sand and fine loam, placed in a brisk heat, and covered with a bell-glass; they will root in four or five weeks, after which inure them to more air, and let them have plenty of light, but not much sun until they have become more fully established, when they should be removed into 5-in. or 6-in. pots. It will succeed in either peat or loam, but I prefer the latter when it can be had of good quality with plenty of turfy fibre in it—whilst the plants are small it should be broken fine; add about one-sixth of sand, according to the nature of the loam, and drain the pot well, as they cannot endure stagnant water. *Cyrtoceras reflexum* does not make a large quantity of roots, consequently it must never be overpotted, and care should be taken not to give too much water, especially until the soil has got well filled with roots. As soon as they have started fairly into growth, the points of the shoots should be taken out to cause them to break, as it has a natural tendency, if not checked, to extend without branching sufficiently. During the summer, the night temperature should be kept about 70°, giving air in the daytime when the heat rises to 80° with a thin shade; syringing overhead in the afternoons will assist growth. Continue the above treatment until the weather begins to get cooler, when discontinue the use of the syringe, as also shading, giving more air and less water to the soil. Through the winter a night temperature of 60° will be sufficient, keeping the plants in the lightest and driest part of the stove; by the middle of February give them 5° more heat in the night with a corresponding increase in the day, but do not re-pot until the roots have got well into motion; and as one shift in the season will be quite sufficient, it is well not to move them till April, when they should be put in pots 3 in. larger, now using the soil in a little more lumpy state. Tie the branches well out, bending them down close to the rim of the pot: this will have the effect of causing young shoots to push up from the collar; at the same time pinch out the points of those existing. As the weather gets warmer increase the night temperature to 70°, and proportionately more in the day with a little shade, damping overhead when the house is closed. All that will be requisite during the summer will be a continuance of the treatment recommended. Most likely a few flowers will be produced by the strongest shoots, but it will not be advisable to move them out of the stove, as the object will be to get

them to make as much growth as possible. In the course of the summer the tops of the strongest shoots may be tied down, which will still further induce them to break back, and in this stage of their growth will be found more effectual than stopping, which latter operation does not always cause this plant to branch out several shoots, as in the case of the majority of subjects. Treat through the autumn and winter as before. Again, in spring give more heat as the advancing season demands it, and re-pot into pots 3 in. larger in size than before, tying the branches well out, so as to leave the plant quite open in the centre, to still further induce the production of young growth from the base. This *Cyrtoceras* is one amongst a number of subjects that require especial treatment in this respect, for if left to its own course, it would spire up to a considerable height and become naked at the bottom; whereas, if the strong shoots be kept tied well out, the position to which they are thus bent causes the annual production of fresh growth from the bottom that takes the place of any branches that become derided of leaves at the base, which should be removed. If the progress made be satisfactory, the plants will this summer bloom freely, each shoot producing a number of their epaulette-like bunches of flowers. After the flowers are formed it is better not to syringe overhead, as it sometimes has the effect of causing their dropping off. The subsequent treatment of the plants will require to be similar to that so far recommended. When grown to their full size, 13-in. or 14-in. pots are large enough for them; after they are fully developed they should be turned out each spring, the drainage examined, and such of the upper portion of the soil as is not occupied by roots removed and replaced with new. When they have arrived at a size such as we now suppose them to be, they will be much benefited during the summer

by liquid manure once a week, but in using it to this and similar spare-rooted plants it must never be given either so strong or in such quantities as with naturally robust growers; it is even necessary to be careful never to apply water at all until the soil is somewhat drier than with most stove plants, or destruction of the roots will sooner or later be the result, especially during the winter when no growth is progressing. I may add that when this plant is thus injured at the roots, it has not the power to recuperate itself like many others. The leaves flag and grow limp. The leaves of the *Cyrtoceras reflexum* are of too tough and leathery a nature to be much injured by the attacks of such insects as thrips, aphides, or red spider, unless when these are allowed to get to a considerable head, yet they will live upon it, especially if the atmosphere in which it is grown be kept unreasonably dry. If affected with these the plants should be laid on their sides and freely syringed, when the insects can be easily removed, the smooth surface of the leaves both on their upper and under sides not affording much harbour for them; the stout substance of the leaves also admits of the water being thus applied without injuring them; where scale has made a home upon a plant it will be found necessary to resort to sponging and cleaning thoroughly with soft soap and water, afterwards giving it a good syringing to cleanse it from all impurities.

T. BAINES.

LUCULIA GRATISSIMA.

This fine old plant, covered with its gratefully-scented and pretty blossoms at the dreariest season of the year, is certainly a sight worth seeing. Hardly a winter passes without commendatory notices of this *Luculia* appearing somewhere, and no wonder, for no one can see a large bush of it in full flower, and filling the whole structure with its fragrance, without admiring it, to the exclusion of almost everything else in the conservatory at the time. Yet, strange to say, it is a comparatively scarce plant; I could not count six good specimens in all the gardens with which I am acquainted, and I do not suppose there are many dozens of really fine plants of it in the country, though it was introduced some fifty years ago. One reason, perhaps, is that it does not succeed well in a pot, and is not very easily propagated by means of cuttings, while every one has not the opportunity of planting it out as it should be, if desired to be grown successfully and easily; for under such conditions it grows as freely as a Laurel bush and requires but little attention. When grown in pots, unless plunged and allowed to remain permanently in the same place, the plant never grows with vigour, and it is subject to insects, and particularly to green fly, which infests the clusters of buds before

they open, and spoils them if not prevented by timely attention; but when planted out in the conservatory border it usually grows and flowers most freely. A greenhouse temperature suits it best during summer, but in order to induce it to expand its flowers perfectly it should not be subjected to a lower temperature than 45° or 50°, with a rise from 5° to 10° on fine days during winter, and this is a higher figure than is considered safe for most greenhouse plants of the hardwood class; hence the *Luculia*, when grown along with these, often fails at the flowering period. Still, those who have no other accommodation

need not despair of growing it on that account; I have seen it do well in such quarters if the situation have been well chosen, as, for example, when the plant was placed near the glass on the sunny side of a house with a sharp-angled roof, so that it received the benefit of the sun when it shone during the short days. In cold houses it should of course have the warmest place if possible, and if it can be trained on a warm back wall all the better. A young plant of the *Luculia*, planted out in a compost consisting of good turfy loam, peat, and leaf-mould, or leaf-mould and sand—but loam principally, if it be not heavy and inclined to be clayey—will make a large bush in a few years, and yield hundreds of blossoms, which last a long time in perfection, and which continue to expand in succession for six weeks or two months. As soon as the plant has done flowering, all the shoots should be cut back without hesitation to one or two buds, for they grow from 18 in. to 2 ft. during the summer. An old plant when pruned, though it looks like a mere scraggy stump, makes a very large and shapely bush before the end of summer, and every shoot is furnished with a well-developed truss of flower-buds, which begin to open about Christmas if the temperature be suitable. During both the growing and flowering season the roots must be well supplied with water, and care must be taken that the mass of roots near the stem does not get dry; at the same time the *Luculia* is impatient of a wet or sour soil—conditions

Gilbert White's Garden—another view (see p. 26).

not likely to arise, however, if the bed in which it grows have been well drained, and seeing that it is such a vigorous grower. Established plants of it should not be afterwards disturbed by lifting or moving, unless a good ball can be got with the roots, and this is not an easy matter, as they are not of the soil-holding kind.—J. S. W.

GLAZING HOTHOUSES.

THERE are now various systems of glazing hothouses in vogue; but the old astragal and rabbet method of fixing the glass and puttying on the outside is still by far the most common, and is adhered to by some of the foremost horticultural builders of the day. It is by no means certain, however, that this is the best plan. We have no objections to the common astragal and rabbet—indeed, we could not suggest a better plan at present; but the puttying outside above the panes might perfectly well be dispensed with, for it does no good whatever, and adds largely to the expense of glazing, in men's time and material; and when the houses get old it becomes a positive nuisance, and also a danger, as may be easily shown. In erecting glass houses it is the usual practice to give the woodwork one or two coats of paint only, and these sometimes rather thin, before glazing, and afterwards to give it one or two more, according to the contract. If the last coats be applied in favourable weather, and if in after years painting be regularly attended to, the putty will last for a considerable time; but if the woodwork have not been thoroughly seasoned—a state of things always to be feared—if it have been painted before it was dry, or if the work have been negligently performed in any way, the chances are that the putty will crack when it gets hardened and leave the wood, and that rain gets in between the wood and the putty; and there is then no alternative but to peel all the putty off and do the work again, if drip and decay are to be prevented. Another objection to outside putty is that, whenever a pane has to be replaced—a frequent necessity—the old putty has to be chipped off before the glass can be put in; and ten to one that pane is left unpainted until the house gets a general coat, and the unprotected putty cracks and become useless in the meantime. And this goes on and on, until the evil is almost beyond remedy; for no work on an estate is so much neglected as the painting of the hothouse.

These are some of the evils of puttying outside, and they are well known, and are to be seen in operation, more or less, in almost any garden; but it is chiefly on the score of economy and convenience in keeping the woodwork in good order that we would dispense with putty. It is not required to hold the glass in, or to prevent drip, which it rather promotes, and we do not know that it is of the least use in any other respect. By far the best plan is simply to "bed" the glass in putty on the inside, and sprigg it above. Some years ago we bought a frame glazed in this way, just to try it, and have been more than satisfied with the results. This frame had received three coats of paint only when we bought it, and has had none since, but it is still perfectly drip-proof and looks as if it would remain so, even if every morsel of paint were washed completely off; and yet there is hardly more than a handful of putty about the whole concern. The sashes are made in the ordinary way, but the astragals are a little stronger than usual, and the glass is cut to fit exactly, and pressed closely down upon the rabbet until the bed of putty is about as thin as a wafer under it, but quite sufficient for the purpose, for the less putty there is under the glass the better. Above, each pane is sprigged at the bottom just above the lap, thus securing both panes at once; and when the woodwork gets the two last coats of paint, the brush is brought over the edge of the glass about one-sixteenth of an inch, which makes all safe. The sashes are 6 ft. long and about 4 ft. wide; but, owing to the strength of the astragals and the angle iron by which they are secured at the middle, they are quite firm and safe, and bear handling much better than sashes glazed in the old way. This system is particularly adopted for pit lights, for in their case outside putty is easily shaken or shifted, unless the sashes are laid aside after being glazed or repaired till the putty sets; whereas, with the others, a pane or two can be put in and sprigged by anybody in a few minutes, without any danger of their shifting.

Were we about to erect a range of houses, however extensive, we should adopt this system of glazing without hesitation. It has all the advantages claimed for "dry glazing," as it is called, without its drawbacks. Some of the plans we have seen of buttoning the glass on, something like slates upon a roof, are good, in so far as they provide an almost unbroken surface to the light; but such structures require a very much greater amount of heating surface to compensate for the escape of heat by the numerous laps of the roof, through which the wind blows as through a sieve. A system of hothouse construction, very much talked of some years ago, failed chiefly

through this cause. The windage from dry laps in puttied roofs even is very great, as we all know, and keeps down temperature more than frost does. Formerly the laps used to be puttied up also, which made the house easier to heat, and the practice was discontinued not so long ago; but, further than this, it is not desirable to practise dry glazing with houses in which high temperatures have at least to be kept up.—"Field."

PLATE LVI.

THE SIBERIAN LADY'S SLIPPER.

(*CYPRIPEDIUM MACRANTHUM*).

Drawn by H. NOEL HUMPHREYS.

THIS is one of the most handsome of all the Lady's Slippers, and the fact that it is perfectly hardy in a sheltered position as far north as York is an additional recommendation, inasmuch as with care it may be grown in the open air almost anywhere. It has been re-imported quite recently by Messrs. Backhouse, of York, and our sketch was made from a specimen that flowered in their nurseries during the summer of 1876. Messrs. Backhouse write that all they know respecting this plant is that it is a native of Siberia and the Ural Mountains. It grows with them in strong and rich soil intermingled with fragments of limestone in a narrow fissure of rockwork. The slope is west, so that the morning sun only catches it partially; "broken sunlight," they add, "is what it prefers." The annexed illustration renders all description of the flower unnecessary, but we may allude to the general resemblance which the petals and lip of this singular flower bear to the distended pouch and wavy tentacles of the common octopus, the white, crimson-dotted, shield-shaped staminode in the centre of the flower representing the head, and the golden pollen-cases, one on either side, the eyes; even the oblique *pose* of the entire flower suggests the motion of the octopods as they propel themselves through the water. It may here be pointed out that there are two Siberian Lady's Slippers, both of which have been repeatedly introduced to our gardens during the past thirty or forty years, but they never seem to have become established. These are, firstly, our present plant, concerning which Messrs. Backhouse may be complimented upon their superior culture, as evinced by the great size and vivid colour of the flowers, unless, indeed, this is a distinct variety due to the same protean variability which attends its tropical allies, much to the confusion of the botanist, although a gain to the cultivator. Another nearly-allied plant is *C. ventricosum*, which has flowers similar both in structure and colour; indeed, it seems questionable whether they are more than forms of the same type. A good coloured figure of this last-named plant may be found in the second series of Sweet's "Flower Garden," vol. i. t. 1, and also in Reichenbach's "Flora Germanica," vol. xiii. t. 497. To cultivators, however, botanical affinities are matters of but little moment; to them the chief point of interest will be to know that these Siberian *Cypripediums* rank among the most brightly coloured and distinct of all the hardy Lady's Slippers. B.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Echeveria Peacocki from Seed.—I consider this the handsomest of all *Echeverias* yet introduced. I bought one plant of it two years ago, and having managed to flower it and ripen seed, I am now in possession of many dozens of seedlings. This is apparently the only way to increase the stock of it, as my plant has never produced an offset.—W. W. H.

Hedychium Garduerianum planted out.—This fine old plant, often found in stoves and warm houses, grows vigorously and flowers well planted out in a greenhouse which is merely protected from frost. At Osmaston Manor it is planted out along the back walls of the Vineries in narrow borders, and there grows and flowers freely. A much better result is attained in this way than when the plants are grown in pots.—V.

Forced Lilac.—Few flowers are more appreciated at this season than those of the Lilac, and, what is of equal importance, few plants force so easily. Some plants of the Persian kind lifted last spring were forced very gently, and after the young growth was matured, they were plunged in ashes in a sunny position. These, when introduced to heat early this season, were a mass of bloom on New Year's Day.—J. Gaoon, *Heatham*.

Derbyshire Spar in Plant-houses.—This is one of the cleanest and most effective substances that can be used on which to set plants, or for covering bare spaces under stages, as the more it is washed the brighter it looks. No Moss or other objectionable material of that kind will adhere to it, and if mixed with soil, it may be washed and sifted as clean and bright as when first used.—J. G.

THE KITCHEN GARDEN.

CELERY CULTURE.

To grow Celery thoroughly well entails more than an ordinary amount of labour and expense, hence we seldom find it much cultivated, excepting by those who have these means at command, or in localities where the soil is specially adapted to its culture; Nottingham, for example, is a great locality for Celery culture, and to some of the local exhibitions held there enormous heads of wonderful size and solidity. In the year 1869 an exhibition of vegetables was held at Chalton, a small town near Nottingham, at which there were twenty-eight exhibitors, the prize winners showing heads of wonderful size and solidity. The weights of the six heaviest sticks were as follows—7 lb. 14 oz., 7 lb. 10 oz., 7 lb. 2 oz., 7 lb., 6 lb. 10 oz., and 5 lb. 11 oz. It will thus be seen that even cottagers and amateurs, with merely simple means, often attain better results as regards size than even our foremost gardeners. Quality is the main point to be considered, and this can only be obtained by paying strict attention to the crop from the time of sowing to that of reaping. There are two distinct varieties of Celery, the Red and the White; the former is the hardiest, and the kind generally grown for winter supply, the White being, however, the most useful for early work.

Sowing.

Sowings for supplies of Celery during July and August should be made in heat early in January, White kinds being best. The seed should be sown thinly in pans or shallow boxes, well drained and filled with light, rich soil, covering the seed very slightly with finely-sifted mould or sand. A gentle watering should then be given, and the pans or boxes plunged in a gentle bottom-heat if possible, or they may be placed on a shelf in any warm house. It is a good plan to place a piece of glass over the pans, and on the glass lay some damp Moss. The plants will be up in a few days, when the Moss must be removed, and in a day or two afterwards the glass be taken off and the plants freely exposed to the light to prevent them from becoming drawn. When the plants have made a pair of leaves above their seed leaves they should be taken into a somewhat cooler temperature, where after a week or two they will be ready to prick off into other boxes or pans 2 in. or 3 in. apart. They should then be placed as near the glass as possible in an early Vinery or Cucumber pit, or some other such place, giving them all the air possible. The soil must be kept clear of weeds, and be constantly stirred with a small stick among the plants; and if a little soot be occasionally sprinkled amongst them and well watered in, the beneficial effects will soon be seen. As the weather becomes milder, the plants may be taken out and placed in cold pits or frames, and kept rather closer than when they were in heat. By the beginning of April there will generally be frames at liberty that have been recently occupied by Early Asparagus, &c., if not, a temporary frame must be made and placed on a

slight hotbed composed from old linings, &c. Into the bottom of the frame must be put 4 in. or 5 in. of good rotten manure, and on the top of the manure about 6 in. of good loam and manure in equal quantities mixed together. The plants should then be taken out of the boxes with as much ball as possible, and planted in the newly-prepared bed 9 in. apart; give a good watering, keep close for a few days, cover during cold nights, and sprinkle overhead on sunny afternoons at the time the lights are closed. When planted, the tops of the plants should not be more than 6 in. from the glass, and as they advance in growth, copious waterings must be given them at the roots, and the frame raised a little at a time until the weather is warm enough to admit of its being taken off entirely. When this is the case a good earthing should be given, and another in a fortnight or so afterwards. Fair Celery may be obtained in this way by the middle of July. The first sowing to obtain plants for the open trenches should be made in heat in March, and treated in the same manner as just mentioned, and transferred to the trenches early in June.

This may be planted in double rows 9 in. apart and 6 in. between the rows. The trenches for this batch need not be more than 2½ ft. from centre to centre. This will come into use in August and September. The second sowing should be made in a cold frame in April, or under hand-lights on a warm border under a wall. When large enough, the plants may be pricked out in an open border, prepared in the following manner:—Rake the ground level, and well tread it to make a hard bottom; on this place 2 in. or 3 in. of rotten manure. Tread this well down, and sprinkle a little soot over it to keep down the worms; 4 in. of good loam should then be placed over this and firmly trodden, the surface raked level, and the plants pricked into it 6 in. apart each way. The principal sowing for late autumn and winter supply should be

made early in May on an open border, kept well watered, and otherwise treated as the previous sowings, and transferred to the trenches in the middle or end of July. The Red kinds of Celery are best adapted for this crop. Late Celery requires to be kept growing from the commencement with as little check as possible; and better results will be obtained from plants sown late and kept growing than from those that have been sown early and kept in a stunted condition. Very early Celery is better for being transplanted several times previous to planting out, otherwise it is liable to run to seed. To save seed, the best plants should be selected in the autumn and marked, and in spring lifted and placed in a rich, warm border, and supported with stakes. Plants for this purpose should not be earthed up.

Planting.

If Celery plants have been pricked out on a bed with a hard bottom as recommended, they will be found to come up with a good ball and the roots intact, *i.e.*, if care be taken in lifting them. The best plan is, two or three days previous to planting, to run a sharp knife or spade down the centre of each

Gilbert White's House (see p. 26).

row, and do the same crossways, following this with a good watering, which will settle the soil and prevent any sudden check to the plants. In a day or two a spade may be run under the plants, which may be lifted, placed upon a handbarrow, and carried to the trenches, where they may be planted from 9 in. to 12 in. apart, according to the variety grown and the space at command. There is a difference of opinion as to whether it is best to plant in single or double rows. Where large Celery is required the former is doubtless the plan to be preferred, but good Celery may be grown by planting double rows 8 in. apart; in this case, however, wider trenches will be necessary. When double rows are planted it is not advisable to plant in angles, as is often done, but plant two abreast, each pair being not less than 10 in. or 12 in. apart, unless it is a very dwarf variety that is grown. By planting in pairs the operation of earthing is much more easily accomplished than when in angles, and the roots can be dug up with greater facility. Dull, showery weather is the best time for planting Celery, during which operation the plants should be pressed in firmly, the roots covered 2 in. or 3 in. with earth, a good watering given to settle the soil, and if 1 in. of half-decayed leaves be afterwards spread over the surface, they will prevent evaporation and encourage the surface roots.

Preparing the Ground, Trenches, &c.

Ground that is intended to be planted with Celery in the spring should, if possible, be trenched in the autumn to a depth of 2 ft., or deeper if the soil will allow. If the soil be not already rich, a good dressing of rotten manure should be well incorporated with it during the process. The surface should be left in a very rough state, in order to expose as much of the soil as possible to the pulverizing influences of the weather. The trenches may be dug any time during the winter, and the vacant spaces planted in the spring with early Cauliflower, Lettuce, Endive, or any other crop that will be off the ground before the Celery will require earthing up. It is a very common practice to dig Celery trenches too deep; this should, however, be guarded against, especially for late crops, and when the soil is of a wet nature, for if the water cannot readily drain away from the hearts of the plants during wet weather, the Celery will rot, and disappointment be the result. Trenches 6 in. deep after the manure is added will be deep enough, and this will admit of the trenches between the rows made by earthing being lower than the roots of the plants, by which means good drainage is secured. The width of the trenches and distance apart must be determined by the variety grown, and whether they are to contain single or double rows. For single rows, 18 in. will do if wider cannot be afforded; and for double rows, 2 ft. apart must be allowed. As Celery is a surface-rooting plant, it is necessary to allow as wide a trench as possible, inasmuch as in narrow trenches the principal feeding roots of the plants soon come in contact with the sides, and thus to a great extent escape the benefit of the manured soil specially intended for them. Good Celery may be grown in trenches 4 ft. apart from centre to centre, but if 5 ft. or 6 ft. can be allowed, all the better. Where ground is limited, the dwarf-growing kinds of Celery are the best to grow.

Manure.

The best kind of manure for Celery is that obtained from the stable or cowhouse, and when mixed together these form excellent material. Mr. D'agnell, of Sherborne Castle, well known as an excellent grower of Celery, prepares manure for it in the following manner:—In the autumn large quantities of horse-droppings are collected, and receive a liberal admixture of soot, salt, and lime; the mass is turned over several times to well mix it, and is then allowed to remain for use in the spring. Worms being one of the chief enemies of Celery, manure containing them should be avoided as much as possible; thus, if liberal dressings of soot, salt, and lime be mixed with the manure as mentioned, these enemies will be quickly dispelled. Rank manures and strong manure water should be avoided, as they have a tendency to cause the Celery to become spongy and ill-flavoured. Although soil of a rich, sandy nature is best suited to Celery, yet good results may be obtained in almost any well-drained soil, pro-

viding it is well enriched with manure; indeed, excellent heads are sometimes grown even in peat soil.

Earthing.

This operation should be performed only on dry days, taking care that none but well-pulverized dry soil is permitted to come into immediate contact with the plants. The soil should be chopped down on each side of the trench, and turned over to dry early in the morning, well breaking the lumps as the work proceeds. When the plants are dry, which they will be towards the middle of the day, the operation may be commenced by carefully removing any decayed leaves from their bases, then gather the leaves neatly up together with the left hand, and firmly place the soil round the plants with the right. When all the plants have been served thus, the sides of the trench should be evenly chopped down, and the surface left as neat as possible. Many people tie up the plants with matting previous to earthing, and some use Celery collars; but neither of these plans are necessary, and only involve needless trouble and labour, and earthing can be performed by any intelligent man without resorting to such troublesome means. It is certainly not necessary to earth up Celery when it is growing rapidly, and moreover it is a bad practice. A little earth, pushed down after a heavy watering to prevent evaporation, is all that should be given during the growing season, and it is well known that some of those who grow the finest Celery in the country, do not earth until full growth is attained; indeed, some of them do not earth at all, but effect the blanching by other means. That some persons pursue quite a different course, we are well aware, yet one would think that a single hint would suffice to point out that it is difficult to give abundant waterings to Celery, and impossible for it to benefit by the natural rains, if we pile a sharply-sloping bank of firm earth close along each line long before the plants have attained maturity or vigour: no plant is more benefited by copious waterings than this, naturally an inhabitant of swampy places. The repeated earthings which Celery receives in the majority of gardens are not only harmful to the crop, but the cause of a great waste of time and labour. Common errors are frequently made in its culture: one being that in earthing up the plants too much soil is applied at one time, by which the hearts are covered in, and are thus made to bulge out on one side and become deformed; whereas, when the operation is more lightly done, as well as oftener, the heads are kept upright and the growth is much more vigorous. Another error, which is perhaps the worst, is "earthing" or banking up the crops too heavily in autumn or before winter sets in. This is a very common practice, especially among amateurs, who often cover their Celery over head and ears. This is sometimes done with a view to keeping out the wet and frost from the crops, but in such cases the plants fail to grow from want of air; in fact, as already indicated, they are buried, and consequently soon become rotten; and, though the wet weather may be blamed for this, it may even happen when the ridges are covered with litter or boards. It is therefore obvious that earthing should be done more sparingly, taking care that the growing hearts of the plants are well above the ridges, especially in the case of late crops. If this be done, there will seldom be any reason to complain of crops rotting, however damp and severe the winter may be. Those who protect the ridges overlook the fact that the means employed for this purpose prevent the escape of moisture by evaporation; consequently, the plants are more apt to rot than if their tops had been freely exposed.

Celery in Market Gardens.

In market gardens Celery is grown in bulk much better than we generally find it in private gardens. The crop is large, crisp, and solid, and neither care nor labour are spared to bring it to perfection; indeed, this is the only outdoor crop in market gardens that is persistently watered. The Red and White Solid are the only two kinds cultivated. The seed for the first crop is generally sown in February broadcast, on a slight hotbed, and thinned out after the plants are up. A large or main sowing is made in March, and another for a late crop in April. All sowings are usually made in frames in gentle hotbeds, but Mr. Geo. Steele, of Fulham, sows his main crop on an open-air bed in the last week of February; a trench some 15 in. or

18 in. deep, 6 ft. wide, and any length (say 20 yards), is cast out and filled firmly with fermenting manure, over which a thin layer of common soil is placed. This being levelled and well rolled, the seeds are sown broadcast over the whole surface, and slightly covered by sifting some light soil over them. The bed is then covered with rank litter until the seeds germinate, when the litter is removed during fine days, but replaced at night until the weather is sufficiently genial for the plants to stand without any covering whatever. The seedlings, both in frames and in beds, are freely exposed day and night in favourable weather, and in the case of frames the sashes are lifted until the weather permits of their entire removal. When the seedlings in either case become thick they are thinned a little, and when they have attained a fair size they are pricked out (in May) into sheltered beds in the open air, 9 in. between the lines and 2 in. or 3 in. apart in the rows; Plants from early sowings are pricked out into frames, where they are allowed to remain until time and convenience permit them to be permanently planted out. A great point observed by all growers is to have the ground to be planted with Celery prepared as soon as possible in autumn or early winter by having it heavily manured all over, and trenched and ridged, permitting it to remain in this condition until it is required for Radishes or spring Cauliflowers. Generally the Celery is planted in the alleys between the beds of Radishes, thus leaving the rows 5 ft. apart, or between alternate lines of Cauliflowers in May and June, in which case the Celery will have taken to the soil and begun to grow before the Cauliflowers are all removed. When this sort of interplanting is practised, provision is made at manuring time by marking off the ground in 5-ft. breadths, and giving a quadruple quantity of manure under each line, and into this the Celery is eventually planted, thus saving the labour of re-manuring, which would cause a disturbance of the spring crop. If the Celery, however, be planted in an open field after the entire removal of a spring crop of vegetables, the ground is cleared of all refuse, dug over, and marked off; and if it have not been previously prepared by giving the extra quantity of manure in winter, that must now be applied. For the first crop and the main crop the rows are usually 5 ft. apart; for the late main crop, 4½ ft.; and for the latest or winter crop, 4 ft. apart. No ridges are formed, as is the case with private gardens, but a furrow is merely drawn with a hoe, as for sowing Beans or Peas, but a little deeper and wider; and into these furrows the plants are inserted by means of a dibble. When a clean field is lined off and ready for planting out with Celery, it is precisely like a field of seed-beds, with the beds all 4 ft. wide, and the alleys 1 ft. wide and about 4 in. or 6 in. deep. Market gardeners never plant more than one row of Celery in each line, and the plants are about 8 in. or 9 in. asunder; the strongest are planted out first, and the remainder form successions. Experience has taught growers for market that deep planting is not advisable, more especially in the case of late crops, from which dampness at the root must be avoided; they therefore plant in such a way that, when finally earthed up, the roots shall be above the level of the trenches. The space between the rows is planted with Lettuces, French Beans, Cauliflowers, Coleworts, or Endive. Earthing up is generally performed at three different times. In the first operation, which is done when the plants have made large leaves and gained good strength, the soil is placed about the plants from the intervening space, taking care not to injure the roots of those growing on it. At the two first earthings a hollow is left along by the necks of the plants, so as to conveniently retain a plentiful supply of water. At the third and final earthing, the ridges are well closed at the top by pressing in the soil against the plants by means of wooden rakes; a man going on either side of the ridge, and both, pressing with the back of the rake at the same time, fill up the furrow effectually. Celery is most liberally watered during the growing season, either in the ordinary way, or by means of hydrants, to which 1-in. metal pipes are attached, or common gutta percha hoses; hogsheds placed at intervals in the fields supply water for the purpose. The best method of distributing the water is by the hose, which should be used in the following manner:—One man carries the end of the hose along the ridges, directing the stream of water, whilst another keeps the hose free

from twisting; and if the length be great a third must be employed to help, and to attend to the turning off and on of the water. Towards the end of August the early produce comes into use, and from that time until February a regular supply is kept up. Before lifting the crop, part of the leaves are switched off with a sickle, then, in lifting, a trench is thrown out at the end of a ridge, which is partially levelled, and the crop is removed at the same time; a set of people being employed in lifting, another in wheeling or carting to the packing shed, and a third in washing, bunching, and packing. Sometimes a crop of Celery is grown expressly for use in soups. For this purpose the seeds are sown in June, pricked out as usual, and finally transplanted into rows 2 ft. apart. As they never grow much, this distance is sufficient for them, for they are seldom earthed up more than once, and if kept until the warm weather sets in, they will certainly "bolt," and become useless.

Insects.

Celery is liable to several kinds of insect enemies—one especially, generally termed the Celery fly (*Tephritis ouopordinis*); this lays its eggs on the foliage, and eventually they are transformed into dark brown maggots, incased in thin wafer-like capsules. The only remedy is to pick off the infested leaves and burn them. Celery is also liable to canker when grown in wet or wormy soils. Slugs, especially in moist weather, are very destructive to Celery crops; but their progress may be arrested by dredging along the tops of the ridges with air-slaked lime, or soot, and operating similarly on the banks or hedgerows surrounding the field where it grows. Highly cultivated ground, if inland, is seldom infested by this pest; but where there are neighbouring hedges or banks, these slugs are sure to be found; and, no matter how well tilled the soil may be, their ravages will become apparent unless preventive measures are resorted to.

Celery for Exhibition.

In growing Celery for this purpose, it must be observed that the point of quality prevails over all others; next to this, of course, comes size, but large, coarse heads are of no use for exhibition, and it is inadvisable to try to grow them too large, as is often the case, and this at the expense of quality. Celery is sometimes shown in its perfect form, and at other times is trimmed. In the latter case it should by no means be dressed until just before it is put on to the exhibition table, inasmuch as it will then have a fresh appearance. The best blanched and most perfect heads should always be selected, and they should all be as near alike as possible. We have seen Celery for this purpose beautifully blanched by enclosing the plants in two half-drain pipes placed in an upright position, the cavities being filled with dry sand. Where, however, large quantities are required, this becomes troublesome and expensive. In digging Celery, care should be taken to have always a good open trench in front of the plants, so that the spade or fork can be got well under the roots, and the whole raised up without damaging the hearts. Large quantities are spoilt in many places by being dug by persons who do not pay attention to this matter.

Varieties.

There are now so many kinds of Celery that it is impossible to say which is really the best. Many varieties are known under different names, all of which are said to be distinct kinds, whereas in reality there does not exist more than one-fourth of the number advertised in nurserymen's catalogues. An admirable opportunity for observing this was afforded recently at South Kensington, where prizes for the best three sticks of any white, and the same number of any red kind, were offered, and which brought together thirty lots of considerable variety. From the Society's gardens forty-five so-called kinds were exhibited, but the differences between many of them were indeed minute. Celeries differ materially in colour, in habit of growth, in solidity—both of leaf-stalk and of the entire plant—in flavour and crispness of eating, and in good keeping qualities. As a rule the Red Celeries are thought to possess these latter qualities to a larger extent than White sorts, but this is not the case with all Red kinds.

White Celeries are, however, considered to be the earliest, and are, therefore, invariably grown for the first crop. Some kinds are undoubtedly earlier than others, but much more depends on the period at which the seed is sown and the after culture, than on the early qualities of any particular variety. Probably there are no vegetables of which fewer sorts are grown in any one garden than Celery, one good White and one good Red kind generally being enough; but it is a matter of no little moment to be certain that these sorts are really good, solid, crisp, and well-flavoured. Celeries that have a sprawling habit of growth seldom turn out so well as upright, close-growing kinds. Moreover, the latter are easier to handle in earthing up, and it is only those who perform this operation who can fully understand the difference between the two habits of growth, as upon the manner in which earthing up is performed depends much of the subsequent value of the crop. Among Red kinds none equal, for colour and compactness of growth, the Leicester Red. Very fine and firm are the Sulham Prize Pink and Carter's Incomparable Crimson, both distinct kinds, tall in growth and robust in habit. Another good-looking sort is the Manchester Red, of which there are several synonyms. Among Whites, the best and only true dwarf kind is the Incomparable White, commonly known also as Sandringham White; this is compact, firm, and crisp. Next in height and quality may be reckoned Veitch's Silver White, a good firm variety, the best of the tall kinds being Wright's White Grove and Seymour's Solid White.

Forty-seven reputed varieties were tried at Chiswick in 1874, and of these twenty-three were Red and twenty-four White. These, by the detection of numerous synonyms, were reduced by the committee to twenty, viz., seven Red varieties and thirteen White, which it was decided were distinct. The following were the principal varieties tried and their synonyms:—

Red Varieties.—Manchester Red (syns.—Sulham Prize Pink, True Manchester, and Giant Red).—Plant of strong and vigorous growth; height, 3 ft. 4 in.; head compact; average girth, 12 in.; heart very solid; stalks broad, thick, and fleshy; a very excellent sort, and stands the winter well. This is the largest variety. Ivery's Nonsuch (syns.—Osborn's Select Red, London Market Red).—Plant of strong and vigorous growth; height, 3 ft.; head compact; average girth, 12 in.; heart very solid; stalk very solid, broad, thick, and crisp, and of a fine nutty flavour. One of the best. Kimberley's Red (syns.—Improved Solid Red, Stuart & Mein's Solid Red).—Plant of regular, but somewhat spreading, habit of growth; height, 2 ft. 6 in.; head compact; heart very solid; stalk broad, thick, and crisp, of fine flavour. Carter's Incomparable Crimson (syn.—Carter's Incomparable Dwarf Crimson).—Plant of close, compact growth; height, 2 ft. 6 in.; head very compact, deep rosy-pink; heart very solid; stalk thick and fleshy, and of fine quality. This is the dwarfest red Celery, and a good hardy variety to stand the winter. Webster's No. 1 (syn.—Webster's No. 1).—Plant of somewhat slender growth; height, 2 ft. 10 in.; head compact; average girth, 10½ in.; heart solid; stalk solid, thick, very crisp, and of good quality. Leicester Red (syn.—Major Clarke's Solid Red).—Plant of erect, compact growth; height, 3 ft.; head very round and compact; average girth, 12 in.; heart very solid, blanching well for about 12 in.; the inner stalks broad and thick, very crisp, and of a fine nutty flavour. One peculiarity of this Celery is, that of the core rising about 2 in. in the heart, as if it were to run to seed. This core portion is by many considered the best part. This variety, from its close, compact growth, blanches easily, and is the best Celery for autumn or early winter use, but it does not stand the winter so well. Wright's Improved Grove Red.—Plant of the same appearance as Leicester Red, but somewhat dwarfier; the head is also larger, being 18 in. in circumference; heart large, very solid, and good. This is an excellent sort.

White Varieties.—Grove White.—Plant of strong and robust growth; height, 2 ft. 9 in. This is an exact counterpart of the Grove Red, but white, and possessed of the same excellent qualities. Does not stand the winter so well as other sorts. Incomparable Dwarf White (syns.—Sandringham, Dean's Compact White).—Plant of very dwarf and compact growth; height, 21 in.; head very compact; average girth about 10 in.; heart solid, and of a pure white; the stalks, broad, thick, fleshy, crisp, and of fine quality. This is one of the best sorts, its close dwarf growth renders it easy to blanch with remarkably little earthing-up. It is good for early use, and also stands the winter well. Seymour's White (syns.—Goodwin's White, Northumberland Champion White).—Plant of spreading

habit; height, 3 ft.; head large; heart solid; stalks broad, thick, and fleshy. This is the largest-growing White Celery, and apt to become pithy if very strongly grown. Prizetaker White (syn.—Veitch's Silver White).—Plant of slender growth; height, 3 ft.; head large; heart loose; stalks rather soft but of fine flavour. Dixon's Mammoth White.—Plant of compact, robust growth; height, 2 ft. 3 in.; large girth, 14 in., heart, very large, blanching about 11 in., somewhat soft, but excellent. It stands the winter well. Haywood's White Queen (syn.—Stuart & Mein's Giant White; Goodall's Flat-stalked; Webster's White).—Plant of robust growth; height, 2 ft. 9 in.; head large; heart solid, blanching in about 14 in.; the stalks very large, broad, thick, and fleshy, but without much flavour. An excellent sort to stand the winter. Veitch's Solid White (syn.—Danesbury).—Plant of close compact growth; height, 2 ft. 6 in.; head compact; girth 11 in.; heart, very firm and solid, blanching from about 12 in.; the stalks broad, thick, crisp, and tender. A very excellent variety, and stands the winter well. Boston Market.—Plant dwarf, from 18 in. to 20 in. high; leaflets small, pointed and sharply serrated. This variety is not used to produce a single head, like the ordinary Celeries, having the peculiarity of forming a number of side-shoots or small heads, which are blanched. It is suited for early work, and it begins to run to seed almost as soon as planted out. Frise, Curled or Garroshing.—Plant of loose growth; height, about 2 ft.; leaves very pale green, and deeply cut or curled almost like Parsley. It is very ornamental. The leaves may be used for garroshing, but this variety is of no other use. It is very tender, and runs early to seed.

Celeriac is a kind of Turnip-rooted Celery, the root of which is only used. It is principally used in soups, but is sometimes boiled and eaten as a common salad. It is little grown in England, but the Germans grow it largely and are very fond of it. The seed should be sown in April under a hand-light, or on a warm border pricked out in the same way as Celery plants, and finally planted in rows on an open border 12 in. or 15 in. apart each way. Trenches are not required for Celeriac, neither should the plants be buried deeply in the soil, but the root allowed to swell above the surface, after the same manner as the Turnip. When the plants have attained their full growth it is well to cover up the bulbs with soil, in order to render them whiter and more delicate than they otherwise would be. A rather light, but rich sandy soil is suited best to the growth of this plant. S.

Planting Early Potatoes.—Experience during the last few years has taught us that planting Potatoes too early in the season is both a waste of time and labour, and a source of bitter disappointment. It may therefore be well to warn intending planters of this useful vegetable to defer planting until from the second to the third week in April. Many plant early, thinking to be before their neighbours, but they are often greatly mistaken. The best plan is to lay out the tubers singly in a cool Vinery about Christmas, or in any out-house protected from frost, and where abundance of light and air can be admitted on every favourable opportunity. Thus treated, by planting time they will have made fine, strong, green shoots, when they should be taken up carefully, putting them into drills about 3 in. deep, when they go on growing at once, and will all be fit for lifting at the same time, and will prove much more satisfactory than those planted early and cut down by frost in an early stage of their growth.—S.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Protecting Canliflowers.—Many expedients are adopted for preserving Canliflower heads in good condition and free from frost; but if stored in cellars or close buildings the flavour is soon spoiled, and in frames they require nearly as much protection as in the open ground. The best plan is to tie up the leaves and pack dry Fern or litter amongst them, when they will be in every way better than when stored in any other way.—JAMES GOSCH.

Maize as Food.—At the meeting of the Paris Academy of Medicine, held in November last, M. Fés, of Padua, enlarged on the merits of Maize, or Indian Corn as an article of food. He gave comparative tables to show that Maize is superior to all other cereals in fatty matters, and it may be considered as a perfect food. He also replied to objections that have been made to Maize, accusing it of giving rise to certain diseases, notably pellagra, and demonstrated that the penicillium glaucum, which is supposed to originate this disease, never attacks Maize unless it is damaged. Green Maize deserves the attention of cultivators generally as a delicate and excellent vegetable.

Preserving Stakes.—Would some of your readers kindly inform me as to the best method of preserving wooden stakes or tallies from decay?—W. S., *Broughly Ferry.*

THE PLACE DU LOUVRE.

WELL-PLANTED open spaces, very near handsome buildings, are as yet so uncommon in our cities that we like to take every opportunity of showing their advantages. The airy space and the trees are valuable for their own sakes, but, in addition, there is the very pleasing contrast between the trees and the lines and ornaments of the buildings when the trees come between the eye and the buildings without obscuring them. Happily the recent plantations in Paris are not clipped as the trees are, yet at Versailles and Fontainebleau; we have never noticed the charm alluded to where the trees are clipped into the form of walls, &c. The illustration shows the comparatively young plantation in the Place du Louvre, Paris. In planting near fine buildings it is important to plant so that the trees may only

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Daphne indica is such a general favourite for its deliciously-scented flowers, that no amateur should be without it. It is so much prized for its fragrance that the plants, in consequence of being cut for their blooms, are often prevented from attaining a good size. If in strong, vigorous condition, the growths of last year will have at their bases stout buds for about six of the leaves down from the flower-bearing shoots; when this is the case a good portion of the flowers may be cut with a leaf or two attached to them, as the buds above mentioned will push growth; but, on the other hand, if the growths made last year be weak, and there be no latent buds, the flowers ought not to be cut with any wood, or in all probability the shoots from which they are cut will not grow at all, thereby causing the plants to decrease in size instead of making their ordi-

Place du Louvre, Paris.

partially veil the buildings from the most important points of view and the streets and places near.

Floating Melon Gardens.—In the beautiful Valley of Cashmere, among the Himalayan Mountains, lies a lovely lake called Dal. Floating about on its surface, sometimes carried by the winds from one end of the lake to the other, are numerous small islands, on which grow the finest Cucumbers and the most luscious Melons known. The way in which these floating gardens are made is very curious. All about the main shores of the lake grow quantities of Reeds, Sedges, and Water Lilies. When these grow very thickly together people cut them from the roots which hold them near the shore. The leaves of the plants are then spread out over the stems, making a sort of trestle-work to support the soil with which it is next to be covered. After this has been done the seeds are planted and the floating garden is left to care for itself until the fruits are ready for picking.—“St. Nicholas.”

any progress. It should be kept at the warmest end of the greenhouse through the winter, and care must be taken not to over-water it, as at no time can it well bear any excess of moisture at its roots. *Deutzia gracilis* is a very useful subject for decoration as well as for furnishing cut flowers. If a few plants be ranged at the warm end of the house they will soon come into bloom.

Old Fuchsias that are resting under greenhouse stages or in similar places should be slightly watered and not allowed to become dust-dry, for if this precaution be neglected many of their roots will be killed. Now is the time for pruning them, and they should not be left too high, 18 in. above the pots being sufficient; the side-shoots should be shortened to about two or three eyes from the principal stem; if left higher than this there is a difficulty in getting them well clothed with blooming growths down to the bottom. It is advisable always to prune Fuchsias some time before they are to be started, as if this operation be deferred till after the commencement of their growth, they are liable to bleed, and thereby become very weak. If it be desired to have a portion of these old plants in bloom early, they should be now placed in a light situation, but not in heat.

Cyclamens are invaluable for winter-blooming; they must be well attended to with water, or they will not thrive well; give them plenty of light—a shelf over the path will be found a good place for them. Of herbaceous Calceolarias, the earliest-sown plants should now be put into the pots in which they are intended to bloom; they are very quick-rooting subjects, and lay hold of the new soil in a short time; they are much the best moved to their flowering pots early; let the soil used be of a light, rich description, containing a good proportion of leaf-mould, of which soft-wooded plants are extremely fond. More Hyacinths, Crocuses, and Narcissus, should be put in heat to bring them into bloom; before this, however, see that they have plenty of roots, for their flowering satisfactorily in a great measure depends upon the quantity of these that they possess. Let them be near the glass so as to obtain all the light possible, or the flowers will be poor and weak.

Miscellaneous Vegetables.—A box of Mustard may be sown every week or so in the stove or forcing pit, if a successional supply be desired, for when a longer time elapses between the sowings it gets tough; some plain Cress may also be put in. Should frost occur, care must be taken that Potatoes, Carrots, and Beet in sheds do not suffer; the best protecting material is dry litter or straw. It is a good plan to get in and prepare Pea and Runner Bean sticks in good time; if this work be done early it is an advantage, as later on there will be found much other work requiring attention.

Potatoes.—Those amateurs who are without hot manure or any fermenting material may still have Potatoes quite a month earlier than they otherwise could by the use of a frame made of Lin. boards and covered overhead with mats, either straw or bast. A frame of this sort some 10 ft. or 12 ft. long and 6 ft. broad will hold a quantity of Potatoes, which will be found very useful. Select for planting here some good hardy kind, such as Myatt's Ash-leaf or Hammersmith Kidney; they ought to be immediately put in shallow boxes, having in the bottom 2 in. of soil, in which set the Potatoes, keeping the sprout ends upwards and putting a little soil between them; they should then be placed where they can receive a little warmth under a greenhouse stage or in a warm room. Until they begin to grow the light should be kept from them. When they commence growth let them have plenty of light to keep them stout; treated in this way they will make favorable progress. They may occasionally be sprinkled with a little water to encourage them to sprout; they can be planted out when the sprouts are 2 in. or 3 in. long.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

January 15.—Digging herbaceous border and among bedded Roses. Sowing six lights of early French Forcing Carrot intermixed with Radishes; also a little Incomparable Celery in heat. Potting some Standard Roses for next year's forcing; also some Beans, placing them in second Vinery, and a third batch of Potatoes placed in slight heat. Pricking off Lobelias—five plants in a small 32-sized pot, and placing them in heat. Putting in Vine eyes; also cuttings of Purple King Verbena, Chrysanthemums, Alyssum, Salvia splendens, Heliotropes, and Fuchsias. Planting Potatoes from pots in first pit on a bed of leaves; also some Lilacs in waste corner for cutting. Throwing out trenches and filling them with manure on which to plant Seakale for forcing next season. Planting Sweet Fays. Throwing out holes in which to plant Pear and Nut trees after having trenched the ground. Tying up first Muscat Vines in the main range after the buds have burst. Stringing Peas to keep off sparrows. Fumigating Gardenias and Calceolarias to keep down fly. Sending in winter Bon Chrétien and Colman Pears. Turning manure in order to get it heated for Potato pits. Emptying and re-filling another pit for cuttings, and putting in a layer of ashes. Sharpening Pea-sticks in bad weather. Pruning Roses on pillars.

Jan. 16.—Sowing 150 more pots of Mignonette. Potting Dendrobium Paxtoni and other Dendrobes in Moss and peat fibre. Potting Epidendrum rubescens, Lælia majalis, and Disa grandiflora in a cold house to which air is freely admitted. Putting cuttings of Salvia patens in heat; also some Gooseberry and Currant cuttings. Planting some Apple, Peach, Apricot, and Pear trees; also Raspberry canes. Putting in seventh forcing of Strawberry plants. Fumigating third Peach-house for black fly. Making new Mushroom-bed. Preparing a border for Parsley. The following is a list of Orchids that seem to do well at Mr. Backhouse's nursery in a greenhouse—*Odontoglossum maculatum*, *Epidendrum rubescens*, and *Lælia majalis*, these three both winter and summer. The following occupy

a common greenhouse in summer and slightly warm in winter, viz.: *Lælia autumnalis*, *Odontoglossum retusum*, roseum, membranaceum, and *Oncidium nubigenum*, anrosam, obryzatum. Plants ready for house decoration—*Narcissi*, Roman Hyacinths, *Heliotropes*, *Talips*, *Mignonette*, *Pelargoniums*, *Hyacinths*, *Lilacs*, *Sweet Briers*, *Rhodoras*, *Dentzias*, *Azaleas*, *Primroses*, *Cyclamens*, *Poinsettias*, *Callas*, *Lilacs*, *Lilies of the Valley*, and *Dielytra*.

Jan. 17.—Digging amongst bush fruits. Sowing 300 pots of French Beans and placing them in second Vinery. Potting *Nemophila* and *Saponaria* for baskets. Making rafts for *Saccolabium ampulaceum*. Putting in cuttings of *Gnaphalium lanatum*, and also of *Begonias*. Planting out *Schizostylis coccinea*. Wheeling a portion of the rubbish-heap on to the Gooseberry quarter. Making pegs in wet weather for lower beds. Cleaning Onions.

Jan. 18.—Digging vacant ground. Potting off autumn-struck *Petunias*; also Cucumbers, plunging them in pits, keeping them at 70°, and covering them at night. Shaking out and repotting *Caladiums* and *Hedychiums*. Shifting a autumn-struck *Centaureas* into 6-in. pots. Striking cuttings of *Lobelias* in heat; also cuttings of *Oxalis* and *Heliotrope*. Shifting herbaceous *Calceolarias* into larger pots. Transplanting some Ghent *Azaleas* in order to prepare them for forcing. Putting in additional forcing material, viz., Anne Boleyn Pinks and a row of *Cinerarias* along front of second Peach-house. Manuring Roses liberally; also any Plum trees that annually bear heavy crops, giving two barrow-loads to each. Turning the rubbish-heap in order to hasten decay so that it may be ready for use when wanted.

Jan. 19.—Digging borders in Rose garden. Potting Veitch's Ashtop Potato for wall sides; also autumn-struck *Fuchsias*, and placing them in heat. Pruning Fig trees, and starting house at 58° at night and 63° by day fire-heat. Putting in more Seakale and fourth crop of Rhubarb. Still sending in *Asparagus*, *Seakale*, *Mushrooms*, *Broccoli*, and *Spinach*. Putting seed Kidney Potatoes in hampers in loft, placing them end upwards and singly so as to get strong sprouts. Putting ashes over Peas just coming up. Pruning wall Roses, having finished those on trellises. Planting some Wine-sour Plums.

Jan. 20.—Sowing *Cyclamen* seed; also Little Gem Peas under cases. Taking offsets from *Echeveria glauca* and putting them into slight heat. Potting *Gladioli* in two parts loam, one part manure, and one part peat and sand. Putting *Zygopetalum maxillare* on Tree Fern stumps and placing them in a cool house. Putting in some cuttings of *Monochetum ensifolium* and plunging them in heat; also of Tree Carnations. Planting some Chives, Sorrel, and Royal Albert Rhubarb. Hyacinths coming into flower freely. Raising first Muscats in main range to 63° at night, nearly all shoots from 1 in. to 3 in. long showing fruit.

Orchids.

It is at all times desirable to have the materials to be used in potting Orchids placed under cover immediately they are received, for if the peat, for example, be left in the open air, unless it is stacked in quantity and thatched, it becomes saturated with water, and the most important part of it, the fibre, decays. Those, therefore, who have their peat out-of-doors, except it be well protected, should at once place it under a shed, in order that it may get dry by the time it is wanted. If very wet, it should not be stowed away in bulk, but may be built up one turf wide round a shed used for other purposes, a space of 3 in. or 4 in. being left between each turf to facilitate the drying process. That potting materials for Orchids should be comparatively dry before they are used is absolutely necessary, for they never thrive well when sodden about the roots. In the case of Sphagnum Moss the great object is to keep it as sweet as possible and in a living state; it should, therefore, be placed on a loft over some cold, airy shell, or a place should be made on purpose for it by putting some boards over the rafters. Care should be taken not to press Sphagnum when stowing it away, or to put too great a hulk of it together, otherwise it will die, turn sour, and when used injure the plants. Living Sphagnum Moss is in many cases a test of good culture, for it has frequently been said, with respect to the New Granada *Odontoglossums*, *Masdevallias*, and others, that if cultivators can only succeed in growing the Sphagnum, the plants potted in it will take care of themselves—a statement generally correct.—JAMES O'BRIEN.

Forming a Lawn.—What is best to do with a recently-turfed lawn, coarse and on a sandy subsoil?—B.—[Top-dress with half-inch finely-sifted loamy soil, and sow with a mixture of good Grass seeds suitable for light soil.]

THE FRUIT GARDEN.

ORCHARD FRUIT CULTURE.

I FEEL compelled to dissent from the statement that the best crops of fruit (standard fruits, of course) are produced in orchards under Grass. All my experience goes to show that so far from this being the case, it is exactly the contrary; and if the Grass orchards, say in Middlesex for instance, were compared with those in which the soil is cultivated for under crops, it would be found that the result was immensely in favour of the latter. If here and there in market gardens orchards be found where the trees are in a state of decay, it is either the result of gross neglect in the cultivation of the soil and attention to the trees, or it is caused by old age and an entire exhaustion of the soil for all fruit-bearing purposes. The characteristics of Grass orchards are commonly—Mossiness, canker, unripened or half-dead growth, the fruit small, and if sometimes abundant, yet worthless. Compare with this the characteristics of any good market orchard where the soil is annually top-dressed, forked over, and cropped with bush fruits, salads, Violets, Wallflowers, or bulbous and spring flower roots. These are the crops commonly grown under old orchard trees where the tops have met and vegetable crops would not thrive. Here the trees are full of vigour, clean, and healthy, producing enormous crops of good market fruit that can always be sold at a remunerative profit. In my locality there are hundreds of acres of such orchards, and the growers would simply laugh at a proposal to place them under Grass. I am entirely satisfied that no body of men in the kingdom are more alive to the value of the surface culture of the soil beneath fruit trees than market gardeners. One has but to compare the crops produced in such market orchards as those of Mr. Dancer, at Sutton, with any of the best found on Grass, to realise the immense advantage to the crops found in surface cultivation, dressing, and cropping. For the production of permanent orchard trees, I find our market growers now give the preference to maidens, as sooner producing good fruiting trees. It is their impression that these develop into good trees earlier than two-year or three-year trees, because the removal from the nursery at so early an age induces an earlier and better establishment in their permanent homes; also that these do not require staking and are not affected by the wind, while, as they grow, their root-hold renders them more capable of withstanding the wind later on than is the case with older-planted trees, all of which require stakes and a larger amount of attention than it is possible to give them. With maidens it is possible to have any form of growth the grower may prefer; but older trees must have been previously fashioned into shape. In sheltered orchards the standard is still preferred; but where winds prevail, a dwarfed form of growth proves most advantageous. For the ultimate success of the trees for the first few years a little careful pruning is requisite, and protection for the stems from hares and rabbits, and from careless labourers. When once established and in fruit, an occasional thinning of surplus branches is all that is needed. Small trees that produce a few pecks of fine fruit are all very well, but it is the large standard orchard trees, producing crops of several bushels, that pay the grower.

A. D.

THE PHYLLOXERA AND INSECTICIDES.

WE have received some reports communicated to the French Academy of Sciences dealing with the attempts which have been made during the last three or four years to arrest the mischief done by this insect, and ultimately to destroy it altogether by means of some potent drug. It is obvious that the remedy to be employed must possess two qualities at starting, viz., it must destroy the insect, and it must not damage to any great extent the Vine. But, further, it is not sufficient that when put in close contact with the roots of a plant—as in a pot—it should prove fatal to the insect, it is necessary, if the remedy is to be of real practical value, that it should reach and destroy the Phylloxera on all the parts attacked by it in Vines which are planted out in the open air. This, according to "Nature," is the real difficulty to overcome, as the remedy, be it in the form of solution or of vapour, cannot easily permeate the soil—sometimes clayey, sometimes sandy—on which the Vine is growing, so as to reach and act

upon the smaller root branches, whose nutrition the Phylloxera diverts into itself. M. Mouillefert, a professor at the School of Agriculture at Grignon, was the person delegated by the Academy of Sciences to make the necessary experiments for the purpose of determining what agent was the most practically applicable to the destruction of the Phylloxera, and the account of the numerous substances employed by him with varying results fills no less than 200 pages of a memoir presented to the Academy of Sciences. It is not our intention here to do more than give a brief résumé of the results at which he arrived. He divides the substances used by him into seven groups, the first of which was composed of manures of various kinds, such as guano, superphosphates, farm manure, &c.; the second of neutral substances, as water, soot, and sand; the third of alkalis, as ammonia and soda; the fourth of saline products, amongst which were the sulphates of iron, copper, zinc, potassium, and ammonia, alum, and sea-salt; the fifth of vegetable essences and products, as decoctions of Hemp, Datura, Absinthe, Valerian, and Tobacco; the sixth of empyreumatic products; and the seventh of sulphur compounds. It was only with some of the substances contained in this last group that really satisfactory results were obtained, and it is to M. Dumas, the permanent secretary of the French Academy of Sciences, that the credit is due for suggesting the employment of the alkaline, sulpho-carbonates of potassium and sodium and those of barium and calcium. All the other classes of remedies mentioned above were either without effect on the Phylloxera or, in destroying it, also destroyed or damaged the Vine. The sulpho-carbonates, which were carefully studied by the great Swedish chemist Berzelius, are obtained by combining the alkaline mono-sulphides with the bisulphide of carbon, are either liquid or solid, and emit a powerful odour of sulphuretted hydrogen and bisulphide of carbon. The alkaline sulpho-carbonates in the solid state are of a beautiful reddish-yellow colour and deliquescent, but are not easily obtainable in that condition; the sulpho-carbonate of barium can be easily procured, however, in a solid state, and presents the appearance of a yellow powder, but little soluble in water. The sulpho-carbonates decompose under the influence of carbonic acid, forming a carbonate, and evolving sulphuretted hydrogen and bisulphide of carbon. These two latter substances are gradually liberated, and as they have a very powerful effect on the Phylloxera, one can understand that the sulpho-carbonate, placed in the ground, may prove, by its slow decomposition, a powerful insecticide. In the case of the sulpho-carbonate of potassium, over and above its toxic effect, it has a direct invigorating influence upon the Vine, as the carbonate of potassium is an excellent manure.

The employment of the sulpho-carbonates as a means for the destruction of the Phylloxera was suggested to M. Dumas by the clearly-recognized need that there was of some substance that would evaporate less quickly than the bisulphide of carbon. He saw that it was desirable to apply the insecticides in some combination which would fix them and only allow them to evaporate gradually, so that their action might continue long enough in any one place to infect with their vapours all the surrounding soil. But the task of eradicating the Phylloxera has by no means been accomplished by the mere discovery of the value for the purpose of these substances; there is the further difficulty of applying them to the Vine in cultivation. One thing seems certain, that in order to render the sulpho-carbonates practically efficacious in killing the insect, it is necessary to use water as the vehicle by which they may be brought to all the underground parts of the plants, and that the best time of year for their application is the winter or early spring, when the earth is still moist and the quantity of water necessary to be brought on to the ground by artificial means is consequently less. Mixed with lime in the proportion of two parts to one, these sulpho-carbonates give a powder which can be spread over the ground before the heavy rains, that is, between October and March, and which will probably prove itself very efficacious.

The conclusion at which M. Mouillefert arrives at the end of his report is that the efficacy of the sulpho-carbonates is proved, and all that is necessary is to bring to perfection their employment in agriculture, which can only be accomplished by the intelligence and practical knowledge of the Vine-grower who is well able to discover the economic processes of culture which are conducive to their successful application. He ends by saying that "Science has accomplished its mission, and it remains for Agriculture to fulfil its part" in the eradication of the Phylloxera from the vineyards of France.

Starmer Pippin Apple.—This is an Apple that cannot be too highly recommended, and one which ought to be in every collection of fruits. I have found it to be a strong grower and a good cropper. It is good in flavour, and will keep without shrivelling from February to June. Those who are at this time of year making new plantations of fruit trees should not omit this, in all respects, excellent Apple.—J. C. S. W.

STANDARD FRUITS OF AMERICA.

THE "Country Gentleman" compiles from the "Fruit Catalogue" of the American Pomological Society, the most popular fruits of the Union, as follows:—"We have been much interested in looking over some portions, and counting the votes given in the different States to the most popular sorts as they are exhibited by the single and double stars on the pages of the catalogue, those recommended for cultivation being designated by a single star, and such as possess great superiority by double stars." Taking the list of

APPLES.—Amongst these we find the greatest number of votes for Red Astrachan and Maiden's Blush—the former with 13 single and 21 double stars, the latter with 22 single and 11 double stars. Yet neither of these are of high quality or flavour; but they succeed in nearly all the States of the Union, and are eminently profitable in many. On the other hand, the Swaar and Eeppus Spitzenburg, which stand pre-eminently for high flavour, have respectively only 9 and 13 votes, all single stars but one—showing that where growth and productiveness are absent, excellent quality is not enough. Local popularity is indicated in the case of the Baldwin and Rhode Island Greening at the East, and Ben Davis and Winesop at the West. Baldwin has 11 double and 7 single stars, nearly all in the North-eastern States; Rhode Island Greening has 9 double and 8 single stars, confined to nearly the same territory; Ben Davis and Winesop have nearly the same votes at the West. Among other popular sorts we observe the following:—American Summer Pearmain, 18 single and 5 double; Carolina Red June, 14 single and 8 double (mostly South and West); Duchess of Oldenburg, 13 single and 10 double; Early Harvest, 22 single and 8 double; Fameuse, 16 single and 8 double; Gravenstein, 21 single and 7 double; Hubbardston Nonesuch, 13 single and 7 double; Jonathan, 12 single and 6 double; Sweet Bough, 19 single and 6 double; Roxburgh Russet, 11 single and 6 double; Summer Rose, 20 single and 3 double; Tallman Sweet, 17 single and 5 double; and Twenty-Ounce, 14 single and 4 double.

PEARS have a more extended range than Apples, and many succeed in every State of the Union. Bartlett, of course, leads the list, having 15 single and 21 double stars. Seckel has 19 and 16, Beurré d'Anjou has 12 single and 18 double. After these the most popular are Flemish Beauty, Lawrence, Howell, Winter Nelis, and Doyenné d'Été, Duchesse d'Angoulême, and Belle Lucrative. The following do well and are recommended in many States, but do not stand so high in character as those preceding, namely, Giffard, 21 single and 4 double; Buffam, 25 single and 1 double; Onondaga, 22 single and 2 double; Osband's Summer, 19 and 1; Tyson, 20 and 2; Vicar of Winkfield, 20 and 3.

GRAPEs.—The Concord is above all others for general popularity, from Nova Scotia to Texas. Thirteen States are quoted as recommending it for general cultivation, and twenty more give it double stars. The next are Delaware, Hartford and Ives. Catawba and Norton's Virginia succeed in the South-west; Clinton has a moderate reputation in a large number of States; and Walter is recorded as promising well in no fewer than 21.

PEACHES.—The most generally esteemed of Peaches are Crawford's Early and Crawford's Late. Next in popularity are Oldmixon (a freestone), Oldmixon (a clingstone), Large Early York, Grosse Mignonne, and Cooledge's Favourite. The following are most highly esteemed in the South and South-west, viz.:—Columbia, Eaton's Golden, Heath (clingstone), Lady Parkham, Lemon (clingstone), Oldmixon (clingstone), and Susquehanna.

CHERRIES are confined to the Northern and Central divisions of the Union. None succeed in any of the Southern States, although a few single votes come from Arkansas for some of the Dukes and Morellos. In regions in which they succeed, the Early Richmond takes the lead for general adoption, followed by Black Tartarian, various Morellos, and May Duke.

APRICOTS are confined mostly to the Middle States, and Moorpark, Peach, and Early Golden are most widely approved.

STRAWBERRIES.—No variety approaches the Wilson for general popularity. Ten States gave it single stars and twenty-two double. Next in order are Triomphe de Gand, Charles Downing, Longworth's Prolific; and after these, Agriculturist, Hovey's Seedling, Downer's Prolific, and Green Prolific.

RASPBERRIES.—Mammoth Cluster takes the lead among Raspberries. Philadelphia gives a large number of single votes; Franconia and Clark about the same. At the east, Orange and Knevett's Giant have several votes.

BLACKBERRIES.—The Kittatinny is the most generally approved among the Blackberries, this and the Wilson standing alone. New Rochelle have several single votes.

This meagre summary does no justice to the catalogue, and only points out a few of the fruits among those which have been extensively tested in the different States.

LEAF PROPAGATION.

THIS method of increasing plants is available in many cases when seeds are unobtainable and when ordinary stem cuttings are either useless or not to be had. Quite recently we hear that Hyacinths may be readily increased by leaf-cuttings, and the same practice has also been successful in the case of Hippeastrums and other Amaryllids, Begonias, many Melastomads, Gloxinias, and other Gesnerads; Hoyas, Bryophyllums, and other succulent plants are best multiplied in this manner, and this is especially the case with some Echeverias, Pachyphytums, and Sempervivums of various kinds. Leaf propagation has also proved very successful in the case of Cephaelis Ipecacuanha in the Indian plantations, where it is now extensively grown, and this method of increase is a valuable auxiliary to the root or rhizome propagation devised so successfully by Mr. Jas. McNab in the Edinburgh Botanic Garden a few years

No. 1.—Begonia-leaf propagation.

ago. Apart from the plants which are now known to be easily multiplied by leaf-cuttings, there are doubtless many others which might be increased in quantity by this simple method if experiments were made with them. Leaf-cuttings of Fuchsias, for example, root very readily, as do also Hoya and Æchynanthus leaves, and when we go a step farther and include the petiole with the axillary bud at its base, and a slice of the bark of the old stem, then we find that Roses, Zonal and Show Pelargoniums, Ficus elastica, and its allies, and very many other Exogenous plants may be readily increased in this manner. Even the modified petiole or leaf-stalk has, in many Endogenous plants, the power to multiply the plant from which it is taken, as in the scales of Lily and other similar bulbs, or the pseudo-bulbs of many Orchids. Among the Cycads, again, the scale-like bases of the petioles

No. 2.—Plant-producing leaf of Bryophyllum.

which clothe the stem will develop their latent buds, and thus form plants if removed and placed in a gentle bottom-heat. The illustration (No. 1) shows a Begonia leaf pegged down on a pan of light sandy soil, before which the principal veins have been nicked or slit with a sharp knife, and it is at these slits and at the base of the leaf where it was severed from the plant that a conglomeration of thickened or descending sap is formed, and from whence the young plants have their origin. Perhaps the best example of spontaneous leaf propagation is that afforded by the leaves of Bryophyllum, which, on falling

from the plant on to a moist surface, develop their marginal buds into young plants, as shown in the engraving (No. 2); indeed, we have seen this happen when the leaf has been suspended in the window by a thread, but the young plants soon cease to thrive unless they are placed in a more suitable position, so that they are enabled to root and obtain nourishment from the soil. B.

CINERARIAS AT CHRISTMAS.

It has been asked (see p. 18) "at what time should Cinerarias be sown to be in flower at Christmas?" As we generally have them in abundance by that date, a few remarks on the subject may not be unacceptable, although the routine of cultivation is similar to that usually adopted. We sow a small quantity of seed in a moist heat in February, and as soon as the young plants are large enough to handle they are pricked off into boxes in light sandy soil, and replaced in heat until they have become well established, when they are potted off singly into 60-sized pots. As by that time the atmospheric heat will be sufficient for them, a close frame set on coal ashes is the best of all places for them, and during the hottest months a shaded situation such as that close to a north wall is best. They should be shifted into larger pots before the roots have become too much matted together, giving larger or smaller shifts according to the size of the plants required. Plants fully 2 ft. in diameter may be grown in 8-in. pots, and if allowed plenty of space, and at all times kept close to the glass, they should not exceed 1 ft. 6 in. in height, lanky, drawn-up plants being scarcely worth house-room. The compost which we employ consists of one-year-old turfy loam, decayed cow manure and sand. The drainage forms an important matter, for although Cinerarias are moisture-loving plants, even the slightest amount of stagnant water often proves fatal to them. They must never, however, be allowed to become dry, but by keeping the ashes on which they stand always moist, much less water will be necessary. By the end of September they should be sturdy plants well established in their flowering pots, and should be transferred to a light, sunny position, such as a pit in which Melons or Cucumbers have been grown, levelling the soil, and surfacing it with coal ashes, in order to keep down worms; under such circumstances they will succeed better than on dry, airy stages, flower-stems will quickly appear, and the plants will be dwarf and well branched. Fire-heat, only sufficient to exclude frost, should be employed, as they dislike forcing; and, as regards insects, our plants are seldom attacked until they are in flower, when we are compelled to place them in both a warmer and drier atmosphere than is congenial to them. Cinerarias in the form of single specimens, when well grown, make excellent vase plants for indoor decoration, or for mixing with forced plants in conservatories; the various shades of blue are exceptionally attractive in contrast with Deutzias and similar plants. If seed be procured from good varieties, so excellent and varied is its produce that no other means of propagation are necessary, except in cases in which a collection of named varieties is grown for special purposes. Winter need not be dull as regards flowering plants where advantage is taken of the resources available, and among these the Cineraria plays an important part. J. G.

CYCLAMENS WITH SMALL FLOWERS.

"J. E.'s" CYCLAMENS appear to be robust in growth, or I should attribute their unsatisfactory condition to defective root action. I should however, recommend an examination of the roots, which may be easily done without in any way disturbing the ball. If the fibres appear white and healthy then the fault will not lie there; if on the contrary, they are black and soft to the touch, too much water has been given. I should, however, rather attribute the imperfect formation of the flowers to a confined atmosphere. The present season has been so dark and at the same time so mild, that Cyclamens have required all the air possible to keep them from becoming drawn. They cannot, in short, be kept in health, and the flowers of even the most vigorous plants will invariably become crippled, if they do not obtain abundant and constant ventilation on all favourable occasions. I should advise "J. E." in any case to keep his plants perfectly cool,

leaving on constant air night and day for a time in mild weather, and giving no heat, unless compelled to do so on account of frost. I should discontinue the application of manure water for the present. Indeed its use at this time of the year is always attended with danger to the root; weak soot water may however occasionally be given, taking care not to water before the soil is quite dry, and then giving enough to ensure the thorough moistening of the ball, as insufficient moisture at the root will produce undersized blooms.—JOHN CORNILL, *Esq.*

— Being a successful cultivator of Cyclamens, my advice may be of some service to "J. E." (see p. 3). My plants will be at their best about the middle of February, and as soon as they have done flowering, I put them on a shelf in the greenhouse, which is light and airy, giving them plenty of water until the leaves begin to turn yellow. I then remove them to a cold pit, plunge them in ashes, and give less water, but never let them become dust-dry. In this state they remain until the last week in August, when I shake them out and re-pot them. I then put them back into the same pit, and water carefully at first, but after they begin to grow I water them freely until they show flower; I then give them a little liquid manure, keeping them in the pit or frame until frost sets in, when I place them in a Vinery on a shelf, giving them plenty of water. By this treatment I obtain good foliage and fine flowers. In my opinion "J. E." injured his plants in the spring of last year by keeping them growing when they ought to have been at rest.—J. M., *Usk.*

— It is difficult to answer "J. E.'s" question when he says that his plants are well furnished with foliage but have small flowers. Some varieties do not at first show size of bloom, but enlarge very much after the petals have reflexed. I should advise two or three of the plants to be turned out in order to see if the ball of earth is dry or the roots rotted from over-watering. In the former case, the plants must be plunged in water for some hours; in the latter, the wet soil should be removed and the plants re-potted, giving as small a shift as possible in three-eighths of yellow loam, one-eighth of leaf-soil, and one-half of coarse white sand.—BERKS.

Garrya elliptica in Flower.—What is the name of the beautiful evergreen shrub enclosed? It has only flowered this season for the first time during three years: being much overshadowed by a Scotch Fir, it has had but little chance. The Fir, however, is about to be removed, so as to give the shrub in question a proper share of light. What is the best time and manner of propagating it, its native habitation, and when was it introduced into this country?—P., *Farnbro.* [The *Garrya elliptica* (the name of the shrub sent) is best propagated by layering it in autumn, *i.e.*, when seeds are not obtainable from female plants, which are much more uncommon than the male kind sent. The *Garrya* was introduced from North-west America and California by Douglas in 1828. A female plant of it fruits freely in Mr. Finzell's garden at Clevedon, near Bristol. The female plant was introduced by Hartweg in 1848. It is one of the most beautiful of all winter-blooming evergreen shrubs.—ED.]

Culture of Mrs. Pince's Black Muscat Grape.—This Grape, referred to at p. 17, has, under suitable cultivation, no equal with respect to quality as a late Grape; but, unlike some free-bearing kinds, it will not succeed under any sort of treatment. Like the Muscat of Alexandria, if properly treated, it well repays the cultivator for his extra care. It requires a long season, and therefore every spur should be pruned as the fruit is cut, in order that the Vines may be started as early as possible, that is, when the Grapes hang late. This gives the fruit a better opportunity of getting well ripened before the dull autumn months set in, and improves both the flavour and keeping qualities. It succeeds best in a border composed of good, strong, fibrous loam, with a liberal mixture of old lime rubbish, or refuse brick broken similar in size to stones laid on the roads; be sure, too, that the drainage is perfect, as this Vine requires a very liberal supply of water at the roots. All through the growing season it is almost impossible to give too much, provided the border is well drained. It is naturally a free grower, and requires liberal support to produce well-expanded foliage; in fact, the deficiency of colour in the fruit, and the contracted foliage so often met with, are caused by a short supply of water at the roots.—JAMES SMITH, *Waterdale.*

The Vine Phylloxera.—In the autumn of 1875 I purchased from a nursery six Vines in pots for forcing in January, but after they grew into full leaf, three of the plants unmistakably showed that something was wrong at the roots. I therefore had one of them shaken out of the pot, and I found that the roots were attacked with the Phylloxera. I then threw the other plants to the rubbish-heap to be charred along with prunings of fruit trees. I was lucky in not having had occasion to plant any of them out in the Vineries, but one of the worst-looking plants I reserved on which to try an experiment, keeping it apart from all other Vines. This plant I dosed in the course of the summer with paraffin oil, mixing about

1 pint of oil with 2 gallons of water. The oil was given three or four times, and although the foliage never acquired a healthy colour, the plant did not get worse till the leaves dropped in the autumn. I shall therefore see this year how it succeeds, and whether the Phylloxera is destroyed or wants more oil to complete its destruction. Should any Grape grower be unfortunate enough to have this pest on his pot Vines, I should recommend him to try this remedy, so that a decision may be arrived at as to whether paraffin is likely to prove a cure or not. Perhaps the only safe remedy where Vines are planted out is to stamp it out at once by uprooting the Vines, making fresh borders, and planting young ones; still if paraffin oil be found to be a cure, it might be tried in infested Vineries where the soil in the borders is not very deep.—WILLIAM TILLERY, *W. Beck.*

G. H.

Plants in Bloom Out-of-doors in Ireland.—The past month has been the wettest I ever remember, but extremely mild. The following plants are in flower in my rock garden, which, though only 20 ft. above sea-level, is a good deal exposed, viz., *Erica carnea* and its suitable companion *E. carnea alba*, *Crocus Imperati*, *Ionopsidium acule*, *Anc. v. stellata*, *Dean's hybrid Primroses* and *Polyanthuses*, *Polygala Chalcidensis*, *Gentiana acaulis*, *Wallflower B-leoir Castle*, *Veronica Blue Gen.*, *Lithospermum prostratum*, *Hepatica Single Mauve*, *Saxifraga crassifolia*, *Scilla sibirica*, *Primroses Double White, Double Peach, and Double Purple*.—D. MCC. MAHONY, *The Island, Rochestown, Cork.*

Orchid-flowers and Fog.—Those who possess Orchids are rarely without a number of interesting and beautiful plants in flower. At the present time, when flowers of all kinds are not too plentiful, the occupants of the Orchid-house will compare favourably with the other houses, inasmuch as they are the more valuable because they come in naturally without forcing or coaxing of any kind, and consequently are more durable than those which have been stimulated into bloom. Among others now in flower may be named *Calanthe Veitchii*, *C. vestita rubra*, *C. vestita lutea*, the winter-flowering variety of *C. veratrifolia*, *Dendrobium nobile*, *D. Wardianum*, *D. crassinode*, *Odontoglossum Alexandræ*, *O. membranaceum*, *O. Rossi*, *Laela autumnalis*, *L. anceps*, *Cattleya Triandri*, *Cymbidium Mastersi*, *Cypripedium insigne* and its varieties, one of which, called *C. insigne punctatum violaceum*, is superior to the very fine *C. insigne Maudslayi* (tree): *Lycaste Skinneri*, *L. lampes*, *Sophranitis coccinea*, *Oncidium cheiroporum*, *O. ornithobryceum*, the *Phalenopsis*, &c. These are all very beautiful varieties, different specimens of some of which, as, for example, *Dendrobium nobile*, *D. Wardianum*, and *D. crassinode*, will be in flower for the next six months. The worst antagonist against which the cultivator of Orchids (particularly in and around London) has to contend is the fog. For a long time it puzzled Orchid growers to give a reason why the flower-buds of certain varieties of Orchids (particularly those of the *Phalenopsis*) should frequently in winter turn yellow and die; it seemed strange that the fully-expanded flowers did not appear to be injured: the very small buds also escaped. It was very disappointing to lose the flowers when they were most wanted. Ultimately, on comparing notes, it was found that whenever one collection was injured in this way, the others in the same neighbourhood were in a like condition, and it was remarked that the mischief always occurred immediately after a heavy fog,

and thus the evil was, I believe, traced to its proper origin. I have never heard of any prescribed remedy against the ill effects of fog on the flower-buds of Orchids, but the course which I pursue is simple and generally efficacious. At the approach of fog I have the houses shut up closely, the floors and underneath the stages sprinkled with water to produce humidity, and the flower-buds lightly syringed. The houses are kept closed and the atmosphere in them moist until the fog has disappeared, when if it have been of any duration, the flower-buds are again lightly syringed, placing the plants in the walk to syringe them, so that the drip may not fall on the other plants. If treated in this way the greater part of the mischief will be averted, although many buds may be lost by the night fogs.—JAMES O'BRIEN.

Wood Pavements.—A printed circular has been sent to us containing the following statements in reference to this subject:—Wood pavements have been laid down in New York for thirty years, and are now altogether condemned. New York surveyors have described them as "worse than worthless." Twenty-one miles of them in New York are now being removed. None of them have lasted five years. The New York surveyor states that the yearly repairs for stone in 1874 was £87 per mile; for wood, £392 per mile. Are ratepayers prepared to pay a rate for paving four times in excess of that now paid? We have had experience of it in London. Thirty years ago it was laid down in Oxford Street, and was generally condemned by the shopkeepers as a stinking nuisance, and it was soon discarded. It is the dirtiest of all pavements, the most expensive, and the most unhealthy. Five streets in the City laid with it six years ago have been all condemned and laid with asphalt. The last report from New York is dated June 30, 1876, and it says: "It is useless, however, to deplore the errors of the past, doubtless attributable in this case, as in many others, to the combined influence of jobbery and ignorance." If it is course of action on the part of the vestries be not resisted, in four years the paving rate will be at least 1s. in the £. Wood was laid in King William Street four years ago. It has since then been entirely re-laid, and is moreover in constant repair, no part of it lasting three years at the most, and some scarcely two years.

NOTES AND QUESTIONS—VARIOUS.

Frame Coverings.—Would not the paillassons or straw mats so universally employed in France answer "South Italy's" requirements? They will keep out 10° of frost, and if made so that the straw runs from the top downwards when put on they will shoot off much rain, or at any rate will not retain so much wet as if made in any other way. They should be made of good Bvo straw, which should be cut just before the grain is ripe, being then much tougher than if cut later, and consequently lasting longer. Their manufacture is universally known, and persons for the Continent, and may be learned a few lessons.—J. CORSMILL, *Bristol.*

—I use lashed Wheaten straw mats for covering frames. They are made in the following manner:—I take two pieces of tar twine of equal length and place them 20 in. apart; on the middle of these I place eight or ten straws, cross the twine, and pull tight; I then add more straw, and thus proceed until the mat is of the length required. They make strong, light coverings, and form efficient plant protectors.—W. N., *Peckham.*

Thuja Lobbi (see p. 573, Vol. X.).—I have just measured a specimen of this Conifer, a small plant of which was planted in February, 1862. Its height is now 35 ft. Another plant I subsequently is nearly 31 ft. in height. The latter is the most beautiful, being much broader at the base than the other, and would have been taller, but it was severely root-pruned for removal a year or two ago. Its appearance has been much improved by thinning some of the lateral branches, which makes it less dense and much more graceful.—JOHN GARLAND, *Killerton, Exeter.*

Scarcity of Holly Berries.—Scarcity is hardly the right term, for, as a rule, there are none at all; spring frosts and a summer drought are the reasons generally assigned for their absence; Mr. Darwin, however, in a contemporary, ascribes it to the want of bees. It may be so, but upon that hypothesis, it is difficult to account for occasional plants bearing a full complement of berries, as is the case here; one plant curled over, and perhaps 10,000 without a berry. How could the bees confine themselves to one only?—D. P. FISH.

Slugs and Rare Perennials.—I never remember slugs so numerous as this season, having killed some hundreds in a few days; fortunately the weather is mild, and they do not bury themselves in the soil, but may be found under leaves lodged at the edge of Grass. Put Cabbage leaves at intervals of from 1 ft. to 6 ft. apart on the beds, sprinkle a pinch of bran under each leaf, and reverse them every morning when destroying the slugs. Look especially after *Crocus Imperati*, some of the *Liliums*, *Aster alpinus*, and small *Hellebores*, as these latter are eaten up; the earth before one can see that the plant has started into growth.—BARKS.

Crocuses eaten by Mice and Rats.—I should feel obliged by any of your readers informing me how to prevent mice and rats from scratching up and eating *Crocus* bulbs in beds and borders.—W. T., *Mark: Harborough.*

Manure for Shrubs and Trees.—Can a cheap artificial manure, either in liquid form or otherwise, be recommended to promote the growth of ornamental shrubs and trees?—K. L. D.

Potatoes and Cocoa-nut Fibre.—Would it be a good plan in planting Potatoes in a heavy soil to cover the sets with 2 in. or 3 in. of Cocoa-nut fibre before putting the soil over them?—G. S. M.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

SCARCITY OF COMMON FRUITS.*

IN London and other large towns the supply of fruit is almost unlimited for those who have ample funds at their disposal. Strawberries may be eaten in February, and Grapes all the year round adorn the tables of our rich citizens. Unfortunately few comparatively are in this happy condition, and the majority of householders of limited means feel the scarcity and dearth of fruit, not only when at home, but even when they are away at any so-called out-of-town locality. Indeed, I might almost say that at a distance from towns it is almost impossible for a stranger to get fruit. The reason for this is of course easy to find. The supply of fruit is not at all adequate to the demand of even large towns; high prices can be obtained for it in the richer centres of population, and as the means of communication are now cheap and easy, everything is sent away from the country. In this way, what little is grown in villages can only be obtained in towns. In the suburbs of large cities again, and especially near London, market gardeners only supply the markets, and even the suburban shops are usually kept up by sending to the great markets in London for their main stock. In saying this I do not mean to suggest for a moment that this arrangement is commercially incorrect; I have no doubt it is necessary, and for the more costly and the best fruit this mode of disposal must always be maintained. Some of the largest consumers of fruit are the manufacturers of jams and preserves. Round London one or two well-known firms have regular travellers who look out for, and buy up for the best price, any crop of fruit which is really sound and good. This manufacture, though highly important, and, indeed, almost essential, in order to give palatable winter food, tends to reduce still further the supply of fresh fruit during summer. A good deal of fruit is imported from abroad, and, indeed, we owe many of our commoner fruits to the Continent. Great numbers of them were imported in the first instance as special luxuries, and then they gradually became cultivated here. The annual value of the imports of fruit is about £6,000,000; and extensive preparations for an increased production and export are being constantly made in various parts of Europe, so good is the business and so profitable the results. For the imports, as far as they are good and wholesome, we should be most grateful to our neighbours for sparing for our use of their superfluity; at the same time, much fruit of foreign growth cannot be so good as freshly picked fruit coming from close at hand. Some descriptions, such as Pears, Pine-apples, and Plums, may, no doubt, be excellent, but much that is imported is apt to get damaged on the road, and to become stale, and even worse, before it reaches the consumer. However large the importation of foreign fruit may be, it never can meet the demand which must always exist for fresh common fruit. The question then arises, how is this deficiency of good, wholesome fruit to be supplied? Can we hope to obtain very much more from abroad, or must we look to our own small island for what we want. Possibly, as means of communication become even more extended than they are at present—particularly if, by continuing to produce so little ourselves, the price is maintained—we may hope to obtain still more from abroad. Increased inter-communication, however, implies an increased population, and consequently a larger consumption, abroad as well as here, so that what is thus gained in one way may probably be lost in another. I think, therefore, that we must regard our own soil as the field for more increased production, and I feel convinced, as I hope I shall presently show, that this can be done, and that our own island can be made, without sacrificing any other produce, to furnish ample and abundant common fresh fruit simply by the exercise of a little foresight, industry, and thrift. The amount of land

required to supply an ample quantity of fruit per head is difficult to ascertain. Of course, soil varies, and much land that would be good for many purposes is out of the way, and could only be cultivated at an unremunerative cost. The fact, however, that at the present time only about 40,000 acres (that is, 60 square miles—a piece of land less than 8 miles by 8 miles) is all that is set apart for market gardens in this country shows, in spite of the large quantity that is imported, what an amount of fruit may be raised on a comparatively small piece of land. Now every one must have noticed how many small pieces of waste land are to be seen in all directions. In all villages and country roads with which I am acquainted, there are such waste spots. Is it not possible, then, to rescue these for the cultivation of common fruit? It requires only to be gone into in a few villages to show how much land is thus, so to speak, useless; and these odd corners are to be met with in all parts of the country. To begin with, there are the railway embankments, which must amount to many thousand acres. The railways of the country are 17,000 miles long, giving 34,000 miles of bank. Say these average only 10 yards wide, the land which this represents is about 200 square miles. Some of this land is admirably adapted for fruit culture, but allowing that only a third is suitable in soil or situation for cultivation it would be sufficient to double the area of our present gardens. No one need think that the embankments with care will be unproductive, for every here and there along most lines, where a frugal stationmaster or porter who is fond of gardening is to be found, the banks, and even the stations, are made not only beautiful with flowers, but highly productive in the way of vegetables and fruit. The small pieces of ground attached to cottages in the country form another great field for the cultivation of common fruit. No doubt not a few are now utilised for vegetables and flowers, and the cultivation of vegetables is as important as that of fruit, while the production of flowers is highly desirable from its civilizing and elevating tendency. At the same time no one can visit the cottagers in almost all parts without noticing, if attention be drawn to the fact, how many small pieces of a large proportion of their little gardens are allowed to remain unprofitably employed. This neglect is not only wasteful, but it tends to destroy the beauty and comfortable appearance of the home. Again, in most villages and along roads in all directions there is much land wasted. Why, then, should it not be allotted to the labourers, provided they are willing to turn it to account by cultivating it in their evenings and spare time? I have endeavoured so far to show, first, that a great deal more common fruit is required for the population of this island; and secondly, that, without trenching on the land devoted to other purposes, ample space exists on which the fruit so much required might be grown. The last and the most difficult question, however, remains, that is, how are we practically to promote the cultivation of these odd parcels of land, and make them produce an abundant supply of common fresh fruit for the people? That this is a subject for the Society of Arts, I think, is obvious. In its very early days, that is, over 100 years ago, the Society took in hand the problem of the planting of commons and waste lands with timber trees; and many parts of the country now have, indirectly, cause to be thankful to the then action of the Society both for the wealth of timber which that action was the means of producing, and for the improved beauty of the present landscape. The cultivation of fruit, I think, is as important now as that movement was then; and I hope that, like so many useful movements of this Society, the increased cultivation of common fruits may be promoted by this meeting. If some persons in authority could be induced to set the example of planting fruit trees instead of so many forest trees, a very great deal of useful and wholesome diet for the people of this country would be the result. At the present time we import annually nearly £2,000,000 worth of Apples and other hardy fruits, and there would seem to be no reason why a great deal, if not all this, should not be grown in this country. No doubt the climate is better in the south of France, but excellent Apples and hardy fruits are grown here; and if fruit can be sold at a profit after payment of the heavy carriage from abroad, more extensive cultivation here would surely pay well.

*Read on Wednesday evening last by Mr. G. C. T. BARTLEY to the Society of Arts, John Street, Adelphi.

CYCLAMENS WITH SMALL FLOWERS.

It is a very common thing to see *Cyclamens* with good growth and foliage, yet with small, shrivelled, undeveloped flowers. You will find them like this in some nurseries where such plants as *Pelargoniums*, *Primulas*, and *Cinerarias* are well grown, and where watering and ventilation are understood. In these places the defect is not caused by the use of unsuitable soil, nor by excessive or insufficient watering, or want of ventilation in their growing season; but, in my belief, it is caused entirely by mismanagement during the ripening and resting period, and when starting them into growth. I know it to be a prevalent idea that they should be rested in the shade, and when so treated they never get the sun, for they are shaded from the sun when in flower to preserve their beauty, and as soon as the flowers are over they are put in the shade to rest. This is wrong. The corms should be thoroughly ripened by full exposure to light and sunshine, and in a free current of air, with watering just sufficient to keep the bulbs plump. Their resting period should be extended as much as possible, and they should be started into growth very gradually and close to the glass; if they start into growth before the middle of September they require a little shading from fierce sunshine. Watering should be increased very gradually as the foliage develops itself. When the foliage has got well up, and is growing vigorously, then water should be given freely. At no time should the plants be pushed on in heat—a temperature of 50° by day and 45° by night is quite high enough. Light and air in abundance are essentials—a close, warm, stagnant atmosphere is destruction to the quality of the flowers, and so are all kinds of forcing. To those who wish flowers of first-class quality, my advice is to let the plants take their own time in growing. In February, March, and April, the flowers open naturally, and are then at their best; good plants may, however, be got as early as October, but only by skilful growers. In addition to what I have said the following points must be observed in good *Cyclamen* culture:—The soil used should be sweet and be kept sweet; there must be thorough drainage; there should be no grubs or worms in the soil; the plants ought to be kept free from red spider, aphid, and thrips, and clean in the foliage, and they should not be re-potted or crowded. But, and this I wish to impress upon your correspondent "J. E." (see p. 39), unless there is perfect maturation of the bulb, the most skilful after-cultivation will not develop good flowers, in fact, without that they are not in the bulb, and cannot therefore be coaxed out of it.—M.

RESULTS OF THE MILD WEATHER.—*Clematis Jackmani*, at West Croydon, has already made green shoots from 12 in. to 18 in. in length; these are, moreover, by no means weak and spindly as might be imagined, but healthy shoots, such as one would expect to find in April; *Hyacinths*, too, in the open border, have made considerable growth, some plants even showing their flower-buds; and a *Gloire de Dijon* Rose, growing on the front wall of a house, is still in fresh green leaf, and has apparently only just ceased blooming.—C. W. S.

LASIANDBRA MACRANTHA FLORIBUNDA IN WINTER.—This, when struck early in spring, and grown on during summer in a warm greenhouse, re-potting and pinching when required being attended to, makes a good winter-flowering plant, the blooms of which are very useful in a cut state. Three or four of them, placed amongst cut flowers of other kinds at this season, set them off to advantage. Six-in. or 8-in. pots will be found large enough for plants to bloom during the winter months, and the last shift should not be later than August. From plants thus treated we have been cutting blooms all through the winter, and if they are in a house the temperature of which is never above 50° at night, the blossoms last longer, and are of a deeper colour than if subjected to a greater heat.—A. H., *Thoresby*.

SALT AND SOOT AS MANURE.—The "Germantown Telegraph" has published the following relative to the value of salt and soot as manure:—Mr. Cartwright received from the Board of Agriculture the honorary reward of a gold medal for a valuable set of experiments made by him to ascertain the value of salt as manure. Of the soil he used nearly three-fourths was sand; the remainder consisted of calcareous and vegetable matter, with alumina and a small quantity of oxide of iron. Having tried all the usual manures alone and differently combined on Potatoes, he found of mixed manures that salt and soot were superior to all others. One peck of soot and ¼ peck of salt were used to a bed 3 ft. wide and 120 ft. long.

NOTES OF THE WEEK.

CELOGYNE CRISTATA.—A specimen of this useful winter-flowering Orchid in Messrs. Veitch's nursery at Chelsea is now in excellent condition, being furnished with numerous gracefully-drooping flower-spikes thickly beset with buds and expanded blossoms, the latter unusually large. This plant, loaded as it is with pure white and golden-yellow flowers, is very effective.—M.

AFACCIA CRISTATA GIGANTEA.—This is now flowering freely in Mr. Ley's nursery at Croydon. This variety is in every way stronger and larger than the old *A. cristata*; and although its blossoms are not handsome, they are interesting on account of their singularity. The plant in question is growing in an intermediate-house, and is subjected to similar treatment to that given to *Marantas* and similar plants with which it is associated.—S.

THE BEST MARKET PELARGONIUMS.—It may interest some to know that the kinds of *Pelargonium* formerly grown for London markets are now being superseded by varieties of more recent introduction, such as *Mabel*, *Digby Grand*, and *Empress of India*. These kinds are found to be dwaiyer in habit than the older varieties, and their flowers, being of greater substance, are consequently more valuable for market purposes.—C.

HABROTHAMNUS ELEGANS VARIEGATUS.—This variegated form of a well-known plant proves to be even more useful than the species itself, its creamy-yellow-stained foliage rendering it very effective when associated with Ferns or other green-leaved subjects. Plants of it in small pots in the Exotic Nursery, Croydon, are used for the front rows in greenhouses, positions for which they are admirably adapted.—S.

CYDONIA JAPONICA FOR CONSERVATORY DECORATION.—This plant, so effective when in flower in open borders during the spring and summer months, is rarely seen in bloom at this season. Medium-sized plants of it, however, lifted from the open ground in autumn, put into 9-in. pots and forced, are now flowering freely in the conservatory at the Pine-apple Nursery, where, associated with other forced flowers, such as those of *Deutzia gracilis*, *Prunus sinensis*, and others, the bright red blossoms of the *Cydonia* are shown off to advantage. Small trusses of its bloom when wired are also useful for bouquet making.—C. S.

RAPIDLY-GROWN IXORAS.—In Mr. Ley's nursery plants of *Ixora Williamsi* struck from cuttings two years ago, are now from 3 ft. to 4 ft. high, and nearly as much through. From these the flowers have been regularly removed as fast as they appeared and the most vigorous of the shoots occasionally stopped. Under this treatment handsome specimens for next year's flowering are the result.—J. T.

DAPHNE MAZELI.—*Daphne indica* is, as all of us know, a useful plant, but allow me to direct attention to another species which closely resembles it, and which is certainly hardy in England, viz., *Daphne Mazeli*. This is a native of Japan, and has all the appearance of *D. indica*, except the colour of the leaves, which are margined with white. I have a specimen of it here against a south wall which is now showing bloom very profusely. When put there four years ago, it was a very small plant, and it is now 2½ ft. through, and is furnished with some thirty or forty bunches of flowers. It has withstood, merely protected by means of a straw mat, 32° of frost. All who are fond of sweet-scented flowers will be very pleased with this *Daphne*, and on account of its being an evergreen it forms a conspicuous plant the whole year round.—MAX LEICHTLIN, *Baden Baden*.

BOURNEMOUTH WINTER GARDEN.—This building, which was opened to the public on Tuesday last, the 16th inst., is situated in the centre of Bournemouth, and within a few minutes' walk of the sea. Its total dimensions are as follow:—Length, 220 ft.; width, 126 ft.; height, 50 ft.; and floor area, 20,000 square ft. The roof, which is curved, light, and elegant in appearance, is constructed on Messrs. Fletcher, Lowndes, & Co.'s system with patent iron tubular ribs. The building, which is efficiently heated, is skilfully planted with Ferns, Palms, and similar plants, which, when well established, will give it a furnished appearance. The grounds surrounding the building are also tastefully laid out and planted.

THE EDELWEISS IN LONDON.—On the 1st of July last, a small plant of the *Edelweiss* in bloom arrived in Eaton Square. It came from near Batzen, packed in a tin box with a quantity of Moss, leath, and similar surroundings. I turned them all out into a pan, adding some mould, and placed it outside the window of a north room. I laid around it on the Moss some small pieces of ice every day, moving it into the room when the sun was hot. When it reached me, it had five flowers on it, three in full bloom, and two buds, which opened. In August, I found another bud which also opened, and in the following month appeared the last, making a total of seven blooms on a plant of the *Edelweiss* growing in England.—H. A. D.

A WINTER-FLOWERING IRIS (*I. STYLOSA*).

JUBÆA SPECTABILIS HARDY AT GLASNEVIN.

THIS beautiful Iris, which is a native of Algeria, is now tolerably abundant in all gardens in which the more choice kinds of hardy exotics are grown. During the last fortnight it has flowered with the Hon. and Rev. J. T. Boscawen in Cornwall, and also with Mr. H. J. Elwes, at Preston, near Cirencester, and we have likewise seen it in several London trade collections. The large handsome flowers from which the annexed illustration was prepared were sent to us by Messrs. Hooper & Co., of the Central Avenue, Covent Garden, who inform us that it is quite hardy and blooms freely in their nursery at Twickenham, where at the present time we are told a dozen or more of its delicate flowers might be cut. It is called *Iris unguicularis* by some authors, but it was figured in the "Botanical Magazine," t. 5773, as *I. stylosa*, a name by which it is generally known in gardens, and which it is likely to retain. Its flowers, which are said to be among the largest of the genus, have a slender tube nearly 6 in. in length. They are fragrant, and are said by Dr. Moore to be produced from Christmas onwards to the end of January. The body colour of the flower is dark lilac, the bases of the fall petals being white streaked and dotted (as shown in the engraving) with purple. The slender standards are uniformly lilac. Although the plant is quite hardy, its flowers are so large and delicate in texture that some slight protection from rain and rough winds is desirable, unless indeed the position which it occupies is well sheltered and the weather mild. It succeeds in almost any soil.

THIS Chilian Palm, with its graceful, pinnate leaves, was looked upon when first introduced some twenty-five years ago, as a stove plant; in fact, up to that time the only Palm recognized as even half-hardy was the *Chamærops humilis* from the south of Europe, which, however, both as regards vigour of growth and hardiness of constitution, has been completely eclipsed by the Chinese species, *C. Fortunei*, and the Nepaulese species, *C. excelsa*. *Jubæa spectabilis* unprotected has, however, withstood the winter's cold in Glasnevin Gardens for five years, and it is not only acceptable as a type of the Feather-leaved Palm—equally hardy as the Fan-leaved—but judging by its appearance when I saw it last December, it promises to be decidedly the more elegant plant of the two. Surely both species would find favourable conditions for development, even so far north as the Island of Arran, and in all places contiguous to the sea where extreme frosts are unknown. I would esteem it a favour if any of your numerous correspondents would communicate their experience as to the hardiness of the *Jubæa*, explaining at the same time the conditions under which its hardiness has been tested. The conditions that I consider ought to be observed in order to fairly test the hardiness or otherwise of any plant, are, in the first place, that the plant should be young; secondly, if it have been grown in a close house far from the glass, let it be removed to the greenhouse, selecting a position where it will receive the full benefit of the light and a free circulation of air; thirdly, if the growth which it has previously made be

Iris stylosa.

B.

drawn up and attenuated, give it a twelvemonth under the treatment just described, so that it may make a stiffer and more robust growth; fourthly, prior to planting out the following summer, remove it from the greenhouse to a cold frame, where it will have the benefit of full sunshine and exposure during the day, and the protection of the glass during the night, and do not attempt to plant it out until after the longest day, or even the early part of July; fifthly, the selection of a suitable site, such as will furnish quality of soil, depth of drainage, and moderate shelter, bearing in mind that the lowest, and what might at first sight appear the most sheltered places, are frequently the very places in which early autumnal frosts make their effects most apparent; and further, that many of these doubtfully hardy plants starting into growth late in the spring are equally late in completing it, and that the perfect maturing of the season's growth is, as most of us know, the all-important point to be aimed at. As my remarks have a special bearing upon Palms, and as in many cases such plants may have been cultivated in pots for years, till their tough roots have become entwined into a compact mass, it will be advisable at the expenditure of some little time and patience, and at the risk even of some breakage to disentangle the mass of roots and spread them out—the future vigorous growth of the plant will much depend on the care and judgment exercised in this operation. At the outset my intention was merely to record the fact that the *Jubæa* has proved as hardy as our Chinese Fan Palm; but I have been led into these somewhat discursive remarks by having observed that the verdict of "not hardy" is sometimes applied to certain plants without the chance of a fair test being given them.

JAMES C. NIVEN.

Botanic Gardens, Holl.

Crocus Imperati in Winter.—This beautiful *Crocus* is now in flower with me; on a small potful of it there are five expanded blossoms, each of which has six petals; the three exterior ones are pale saffron at the back pencilled with dark lines, and soft pinkish-lilac on the upper surface; the three interior petals are the same colour back and front, and only slightly pencilled; the centre is yellow, with yellow anthers and stamens, and when the blossoms are fully expanded they are singularly beautiful. The bulbs were potted early in summer, and plunged in an ash-bed till they began to show signs of throwing up buds, when the pot was taken into the greenhouse to flower.—E. W.

Effect of the Excessive Rainfall on Vegetation.—At last (Jan. 15) we have had a fine day, after a pouring rain nearly all night, as if it had never rained before. Considering the mildness of the weather, it is surprising how little vegetation is out of season. The enormous evaporation consequent on the unusual rainfall has kept plants and buds almost as much back as frosts. This is fortunate as regards our fruit and flower prospects for next year. It is even probable that if frost come at any time during this month it will do but little harm to plants or trees, most of which, notwithstanding all that has been written to the contrary, are in their usual state of semi-rest, though the birds sing at morn and eventide as if it were spring, and the rooks are reconnoitring their old nests. The wind is due west to-day, with signs of frost in the air, and we may, perhaps, hope that the forty days and forty nights that have deluged horticulture out of the garden are almost ended.—D. T. F.

Echium fastuosum hardy in Ireland.—This plant is well described in *THE GARDEN* (Dec. 9) as being the "handsomest of the shrubby *Echiums*." It has been known in cultivation for nearly a century. Our contemporary very truly remarks with regard to it, that "though no more beautiful object can be imagined, few have probably any knowledge of it." After stating that the writer's first personal acquaintance with it was at Mentone, and alluding to its imposing aspect, "distinct from anything in our gardens," he says that in the south of France it thrives in the open air throughout the year, and the hope is hazarded that it will, perhaps, do the same "in the south of England on dry soils;" and then concludes, as a matter of course, that it would grow and do well in "well-lighted, cool houses." Well, here is an old friend, which even in our backward Ireland has been known and grown for more than half a century at least, and found to be perfectly hardy, not only in Cork, Kerry, and other southern counties, but in Westmeath and others far less favoured as regards mildness of climate.—"Irish Farmer's Gazette." [On sending the above to Dr. Moore, he writes to us as follows:—The enclosed statement is at variance with my experience. I have tried large plants of it at Glasnevin, but they have been as often

killed. I am not prepared to state my opinion against its standing out in the south of Ireland, but I have great doubts about its surviving an ordinary winter in Westmeath. I do not recollect seeing this plant except in conservatories in Ireland.]

Hybrid Columbines.—In the summer of 1874 Mr. Isaac Anderson Henry crossed the blue *Aquilegia cœrulea* with the yellow *A. chrysantha*, and the seedlings which bloomed in June, 1876, partook of the character of both parents, the outer reflexed segments being of a delicate lavender-blue, and the inner ones pale yellow. In colour the male parent, *A. chrysantha*, seems to have exerted the most influence. This hybrid is a very handsome one, bearing large, long-spurred flowers, and all the seedlings from this union appear to be the same in colour and general appearance. It may be as well here to direct attention to the fact that *Aquilegias* generally are very susceptible of the influence of foreign pollen, and that but little reliance can in consequence be placed on any particular species coming true from seed.—B.

Striped Phlox Drummondii.—All the striped varieties of this *Phlox* which I have grown from seed during the last few years have been unsatisfactory; their flowers are not clearly and pleasingly striped, but have a confused appearance; we want something better, and must wait patiently until it is forthcoming. Years ago, from 1853 to 1860, there used to be in cultivation an exquisite striped variety of this *Phlox* named General Radetzky, the flowers of which were white, beautifully flaked with rosy-purple. At that time it was propagated by cuttings, and used to appear in plant lists. I think it was originally distributed by Messrs. Henderson of the Pine Apple Nurseries, but an application made to them some time since disclosed the fact that they no longer possessed it, and that there was reason to fear it had become lost. This I was sorry to learn, and should be glad to know if it be still grown by any of the readers of *THE GARDEN*.—E. W.

Outside Decoration of Low Greenhouse Walls.—We often see low greenhouse walls left entirely bare, because for certain reasons it is difficult to get a border wide enough for plant growth. In most cases, however, it is possible to have one 5 in. in width, and if this be made deep enough—say 2 ft.—it will be found to be an excellent place for at least two plants, which, during a great part of the season will decorate the wall in a very striking way. The plants to which I allude are *Tropæolum polyphyllum* and *Brodiaea coccinea*. The *Tropæolum* should be planted 5 in. deep and 4 in. apart, and the bulbs of the *Brodiaea* should be just about 5 in. asunder. When once established they will reach a height of 2½ ft., and during May and June the glaucous grey, odd-looking foliage of the *Tropæolum* forms a pleasing background for hundreds of deep golden flowers; all this, too, is enhanced and brightened by the many umbels of carmine and green-coloured flowers of the *Brodiaea*, which blooms exactly at the time when the *Tropæolums* are at their best. Both are perfectly hardy, and when once planted may, with the exception of a little tying, be left entirely to themselves.—MAX LEICHLIN, *Baden Baden*.

Large *Camellia reticulata* out-of-doors in Ireland.—At Creg, near Fermoy, Co. Cork, the seat of Mr. John Hyde, is a fine specimen of this variety of *Camellia*. It is growing in the open air, and even during winter, no matter how severe the weather may be, no protection is given it except that afforded by the surrounding shrubs and trees, in which respect it is favourably placed, being almost surrounded by Conifers, ordinary trees, and large *Rhododendrons*. It is in the most perfect health, as its dark green, leathery leaves amply testify, and I was informed that it never fails to produce an abundance of flowers every season; indeed, on the occasion of my visit on January 1, the blossom-buds on it might be counted by the thousand, and when in full bloom it must be a sight worth going many miles to see. It measures nearly 20 yards in circumference, but its height is not in proportion to its spread of branches; on the contrary, it is not more than from 7 ft. to 8 ft. high. For many years past it has been allowed to take care of itself, and it certainly appears to be none the worse from want of attention. There are several other large specimens of *Camellias* of different kinds close to it, but although they all appear to be in excellent health, I was informed that none of them flower satisfactorily.—E. R. Q. P.

Permanence of Garden Varieties.—The old test of a species or type was its inherent fixity, its "coming true" from seed under widely varying conditions of growth, but now we know that many of the wild types introduced to our gardens of recent years do not perpetuate their characters more exactly than some hybrids do when raised from seed, while, on the other hand, many sports and variegated varieties re-produce themselves from seed under cultivation as precisely as the purest wild types. This is particularly observable in *Asters*, *Hollyhocks*, *Stocks*, *Zonal Pelargonium Madame*

Vaucher, P. Christine, *Cobæa scandens variegata*, *Mesembryanthemum variegatum*, some Brassicaceous plants, and others. Indeed, when we come to fully realize the permanence of some varieties, and the precision with which they are re-produced from seed, together with the communication of colour or variegation by grafting variegated scions on green-leaved Stocks, we may well ask ourselves whether permanence or fixity in any variety or race is not due to weak characteristics in some cases, as well as to strong ones in others, just as diseases and peculiarities of colour are hereditary in the human race.—B.

SELECT FUNKIAS.

Among good, old-fashioned plants, I am surprised that Funkias are not more grown than they are. They are perfectly hardy, easily cultivated, and very handsome both in foliage and flower. There are only a few species, and of these I think the best are *F. lancifolia*, the smallest, and *F. grandiflora*, the largest of the family. *F. lancifolia* flowers in autumn; it has pale purple blossoms, which last a long time, and it is a good plant for the front row of a border. *F. grandiflora*, when well grown, is a noble plant, with large, pale green leaves, and fine, pure white, Liliaceous flowers, which are very sweet-scented; it is not, however, a very free bloomer. Snails are very fond of the whole family. Funkias should be grown in good soil, and a damp place suits them best. Though quite hardy, they are cut to the ground by the first frost, and entirely disappear during

Funkia grandiflora.

the winter. There are some very pretty varieties with variegated leaves of different forms of variegation, all of which are well worth growing; and there is one species which has the flowers pale purple with a distinct margin of white. This I have never seen, and I do not know if it is in cultivation; I only know it from a figure and description of it in that very useful book the "English Flower Garden," by Mr. W. Thompson, of Ipswich. Its name is *F. albo-marginata*.

Bilton Vicarage.

HENRY N. ELLACOMBE.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Coronilla glauca by the Sea-coast.—In tolerably sheltered spots this stands ordinary winters without protection; it commences to flower before the Christmas Rose, and continues in beauty long after it has faded. As a wall plant, it is very effective, and being not at all particular as to soil, it deserves more general cultivation out-of-doors than it usually receives. Like many other half-hardy plants it is subject to scale and various insect-pests under pot culture, but when planted out it seldom becomes affected.—J. GROOM, *Henham*.

Alonsoa patagonica.—This pretty species received from Patagonia has proved a valuable early and free-flowering annual. It grows about 15 in. in height, and forms densely-branched, compact bushes with at first downy-haired, but in an adult state glabrous, glossy leaves of a cordate-lanceolate shape. The flowers which are vermilion-scarlet in colour, are of fine form and disposed in densely-set spikes.—HAAGE & SCHMIDT, *Erfurt*.

An Effective Flower Bed.—A novel and beautiful effect was produced this season at Mr. Hunnewell's place, near Boston, by planting a bed with the variegated Japanese Honeysuckle, intermingled with an outer planting of Clematis Jackmanni—the purple of the Clematis flowers showing finely on the golden-yellow of the Honeysuckle.—W. F.

Saxifraga oppositifolia on Rockwork.—This is truly a gem on rockwork, and were I limited to ever so few plants I would give this a place. It flowers almost as early as the Winter Aconite; it is evergreen, hardy, compact, lovely when in flower, a condition in which it continues for many weeks; it is indifferent as respects soil if it be furnished with some chips of m. caecous sandstone, and it is equally indifferent as regards aspect if it have but a fair amount of sunshine. It bears frequently dividing, indeed, it succeeds all the better for such treatment.—E.R. Q. P.

THE FRUIT GARDEN.

GRAPES AT HECKFIELD DURING 1876.

So much has been said and written on Grapes and Grape growing, that it is almost a matter of impossibility to write anything new on the subject, and therefore I shall only record my own experience regarding the kinds of Grapes grown here during the past year; and if my notes do not coincide with those of better and more experienced Grape growers, my only reply must be that my system of culture must be at fault, and that I shall be pleased to receive instructions on those points in which I am found deficient. As being the most convenient form, I have arranged each variety of Grape in alphabetical order, and have appended it according to its position of merit at the end of this article.

ALCANTE.—This is one of the most popular late Grapes, but in my opinion very much overrated. It has a good appearance, never fails to colour perfectly, is of the most prolific type, and rarely causes anxiety in respect of shanking, but it has a very thick skin, and though the flesh is very sweet it adheres to the skin, which is another great drawback. It will keep in good condition till March.

ASCOT CITRONELLE.—This is a seedling raised by the late Mr. Standish, who advised me to plant it, as he considered it one of the finest-flavoured Grapes that could be grown, which it certainly is. It belongs to the Frontignan section, and has bunches about the size of the old White Frontignan, berries perfectly round and of pure amber colour, and it keeps in good condition till the end of January. It is one of the best late White Grapes, and deserves to become popular, which, no doubt, it eventually will.

BARBAROSSA (GROS GUILLAUME).—This, when given an abundance of heat, is one of the best late varieties, but if grown in a cool house it is comparatively worthless because flavourless. It is generally considered a shy bearer, but I have found the contrary to be the case. The flesh is most refreshing, and, for a late Grape, thin-skinned. From close observation of the two (so called) kinds growing together, I consider this and Seacliff Black synonyms. My plants were obtained from a good source for distinct varieties.

BLACK HAMBURGH is too well known to need description, though it may be well to add that novices starting Grape growing will be wise to grow this kind only.

BOWOOD MUSCAT.—Very little, if any, different from Muscat of Alexandria; for though sometimes I have fancied I could detect a marked distinction, when the two have been placed in juxtaposition the difference was not perceptible.

BUCKLAND SWEETWATER.—One of the finest looking early White Grapes that can be grown, but the flavour when the fruit is at its best is but second-rate, and becomes quite insipid if left hanging long after being fully ripe. The Vine is a strong grower, but a somewhat uncertain fruiter.

BURCHARDT'S PRINCE (ARAMON) is generally considered a good late Grape; and, so far as its keeping properties are concerned, this is quite correct, as it will hang in good form till March. I have, however, decided to discard it on account of the earthy flavour it leaves on the palate, and, with me, its inability to colour properly. It has proved to be a good variety for outdoor growth, as I had some good samples of fruit from a west wall in the past season, from which circumstance it should be tried in places where other varieties do well in the open air.

DUKE OF BUCCLEUCH is one of the largest, perhaps the largest, Grape yet known and remarkably early. Last season it was quite ripe a month before Hamburgs growing in the same house, but began to decay at the foot-stalks of the berries in a very few days after being fully ripe, so that I have reluctantly decided to discontinue growing it. It is of a robust constitution, and shows fruit freely; and for a market grower who could be certain of customers for the fruit the moment it was ripe, it would prove quite invaluable and certainly profitable.

DUCH SWEETWATER.—A well-known, very early kind; indeed, I am inclined to give this a first place as an early White Grape, for although the bunches are comparatively small and the berries occasionally irregular in size, it is a certain fruiter, and of the most exquisite flavour; it is one of the best kinds for pot culture, as also for the cool greenhouse and open air.

FOSTER'S WHITE SEEDLING is another good early variety, being larger both in bunch and berry than the preceding, and, if it had but the same delicious flavour, would, as an early Grape, be as near perfection as possible; this is also well adapted for a cool Vinery,

and those in search of a white companion for Black Hamburgh could not make a better choice.

FRANKENTHAL is considered by some identical with Black Hamburgh, but as growing here the distinction is very decided, especially in the fruit, which is perfectly round and always carries a deeper bloom, while the fruit of the true Hamburgh is more inclined to an oval shape, and is rarely "hammered," as is the case with the fruit of Frankenthal.

GROS COLMAN.—The largest Black Grape I have yet seen, and by no means so coarse in flavour as generally believed. I grow it largely here, and connoisseurs in Grapes praise its flavour greatly. The reason of its being so summarily condemned by many is doubtless that it has never received justice at their hands, being grown only in a cool house, for which it is not suited, as it requires a long season and plenty of heat to bring out its saccharine qualities. It is a remarkably free-growing and fruiting Vine, producing bunches of very large, and berries exceeding 1 in. in diameter. It is difficult to colour well, and the only way to succeed in this is to allow it a long season, to let the laterals run, and to keep heat in the pipes with plenty of ventilation night and day. It will remain plump and fresh till February, and must therefore be classed as one of the best late Grapes, especially for the market-grower.

LADY DOWNES SEEDLING.—Taking all points into consideration, this is a long way at the head of the list of late Grapes. I know no other kind that can compete with it for late keeping combined with quality, and I am quite at a loss to understand the preference sometimes awarded to Alicante, which, in my estimation, is far inferior to it; I admit that Alicante is much easier to grow, still, the extra care involved in the culture of Lady Downes is much more than compensated by the superiority of the fruit. Alicante shrivels by March, and even sooner; Lady Downes never fails to be plump and fresh to the middle of May, while its flavour is vastly superior to that of Alicante. Like all other late Grapes, it should be afforded plenty of heat at nearly all stages of growth, and if this be given, together with hourly attention when the berries first begin to change from the sour to the saccharine state, to prevent scalding through insufficient ventilation, no other late Grape can compete with it in either quality or productiveness.

MADRESFIELD COURT.—This is one of the best-flavoured Grapes grown, and now that its peculiarities of culture have become known, it is daily rising in favour. My opinion is that it should be grown in a house by itself, where it could receive special treatment as to moisture, &c., should signs of its one great fault, viz. cracking, put in an appearance. It was first sent out as a late Grape, but I have never been able to keep it longer than November, and even by that time it shrivels very much; I therefore class it as a midseason Grape of the first order.

MRS. PINCE'S BLACK MUSCAT.—Like many others I have failed to colour this variety satisfactorily, though during the past season it did better in this respect than usual, and I hope this year to further improve it. I have a notion that if all its lateral growths were allowed to run at random for a fortnight or more previous to the colouring period, and till the process was completed, that we should have little cause to complain of lack of colour. It is of a rich Muscat flavour, and keeps in good condition to the end of the year, so that it can hardly be classed as a late Grape, such only being considered late varieties that keep till March or April.

MUSCAT OF ALEXANDRIA.—This, like the Black Hamburgh, is too well known to require any comment; therefore I will only remark that it is by far the best late Grape in existence, as it will keep with care if well ripened in good condition until the end of March or April.

RAISIN DE CALABRE.—This is a very good late Grape of the non-Muscat class, having bunches of large size and perfectly round, medium-sized berries. If ripened in heat the flavour is good, but if in a cool house, it becomes insipid, and the skin tough and hard. It is one of the most fruitful kinds, scarcely ever failing to show three or more bunches on each shoot.

TREBBIANO is another of the same class as the foregoing; indeed, it is puzzling to distinguish between them, and to me the only discernible difference is in the berry. Trebbiano being inclined to be of an oval form, while the Raisin de Calabre is round. The flavour and growth are the same, and both delight in heat.

VENN'S BLACK MUSCAT.—Two Vines of this kind have fruited here during the past season, but as I do not consider that they received full justice as to culture, I reserve my opinion of its merits till another year; I may say, however, that it is either a seedling reproduction of Muscat Hamburgh, or a very near relative.

WALTHAM CROSS.—This has failed to grow or fruit to my satisfaction, and I have therefore resolved to inarch Golden Queen on its stock. Its most serious fault with me has been its tendency to small,

stoneless berries. I should be glad to know how it is succeeding with other cultivators, as I have not seen it anywhere in anything like first-rate condition.

WHITE NICE.—One of the largest fruited kinds, when ripened in heat, of rich piquant flavour, but the Vine is of too vigorous a growth to be recommended for extensive cultivation.

WHITE TOKAY is the finest kind of the non-Muscat class of white Grapes, and deserves to be more generally cultivated. The bunches are large and compact, with berries of good size, and in colour a beautiful amber; the flesh is crackling, very sweet and refreshing, and keeps in good condition till the end of January.

All the above have fruited here during the past season, and some are still hanging, and the notes have been made after due deliberation on the merits of each kind. I place the different varieties as to merit in the following order:—

Black Hamburgh, Muscat of Alexandria, Frankenthal, Bowood Muscat, Lady Downes, Ascot Citronelle, Gros Colman, Foster's Seedling, White Tokay, Dutch Sweetwater, Mrs. Pince, Barbarossa, Alicante, Madresfield Court, Buckland Sweetwater, Trebbiano, Raisin de Calabre, Duke of Buccleuch, Venn's Black Muscat, White Nice, Burckhardt's Prince, and Waltham Cross. W. WILDSMITH.

Heckfield, Jan. 13, 1877.

BOTTOM-HEAT FOR VINE ROOTS.

It may seem almost an anomaly to advocate bottom-heat for Vines. All plants should have their roots as warm or warmer than their tops; such, in brief, is the teaching of Nature and the conclusions of common sense. Every part of a plant should advance simultaneously, if the plant is to be healthy and vigorous, and its produce plentiful and profitable. A large amount of profitless discussion has been expended on the question of the precedence of root or top growth. Practically, it would be wiser to assume that they are correlative and parallel: if subjected to similar conditions, all growth is, in fact, continuous. To write or speak of living plants beginning to grow is anomalous and contradictory, for they never cease to grow. The rate of growth may vary almost to infinity, but growth is nevertheless continuous from birth to death; and this is true alike of top as of roots, though not, perhaps, to the same extent. Each plant is in itself a unit, and its development cannot be divided into top or root growth, as one would divide the contents of a barrel of sugar. The roots of a plant are always in motion, so is the top if subjected to the same conditions. Of course it is possible to arrest growth by cold and dryness, but, apart from these forcible stoppages, growth continues until the complete decay of the plant: the old leaves fall at the summons of advancing life, and not in obedience to the languid bidding of approaching death, and when they fall the buds do but hasten on to a fuller life. They continue to fill and swell larger until their vital power bursts their scaly coverings, and new leaves, flowers, and shoots appear. Now the roots take as active a part as the tops in all these changes and in all this hidden growth, and perhaps a more active one, for, during the greater portion of this period of semi-dormancy it may be safely affirmed that the roots have been in a higher temperature than the tops; in fact, they have been receiving a supply of bottom-heat—for all excess of terrestrial heat over atmospheric or celestial heat may fairly be denominated bottom-heat. Again, the tendency of all substances is towards an equilibrium of temperature. The action of all gases, liquids, and solids, when brought into direct contact with each other, tends to prove this; and the earth is found everywhere to approximate to the temperature of the air, hence the temperature of the roots of the Vine and other plants should run parallel with that of the tops. How far in advance the roots may safely be of the tops for the most successful development of the plants is a vexed question into which I do not propose to enter; for the present I simply contend for an equality of temperature between the tops and roots of certain plants as the most likely means of securing the highest and most satisfactory results. How this equilibrium of temperature is to be maintained is also quite another question. Some advocate the heating of Vine borders from beneath by means of flues, hot-water pipes, or other means, while others declare in favour of warming from above by fermenting material or artificial or

natural heat. Both methods have answered well where skilfully applied.

But a prior question arises—why place the roots of Vines and some other plants in the cold, and the heads in the warmth of glass houses. No one thinks of doing so in the case of stove plants. The cultivator who would plant Stephanotis, Allamandas, Clerodendrons, Passion-flowers, or other tropical plants outside, with their heads in the stove-house, would be considered to have invited failure in the future development of the plants; but I cannot see much difference between such practices and subjecting the heads of Grape Vines to a tropical heat from November till May, while their roots are at the same time in an outside border exposed to most of the semi-arctic conditions of our variable climate. No! the simplest way of providing bottom-heat for Vines is to plant them inside the same houses as provided for the tops; the law of the equilibrium of heat will then take care of all the rest. Our present practice of placing the roots outside and the heads inside has nothing but precedent to stand upon. It is opposed alike to Nature and common sense; no doubt it has often proved successful, but that only proves the power of endurance of the Vine, and how cultural skill has vanquished the most unnatural and absurd difficulties, piled up in its way by red tape and routine: for, indeed, no better reasons can be given for the placing of the roots of early Vines outside while their heads are subjected to tropical conditions inside. The practice of planting early Vines outside cannot be defended on any reasonable grounds. It is directly opposed to Nature, and results inevitably in a reckless loss of cultural and climatal force. The same amount of artificial heat now used to elevate the temperature of early Vineries to the requisite standard would also furnish the roots of the Vines with all the heat they require if these were placed inside the house. But instead of adopting this common and easy method of affording the requisite amount of bottom-heat to Vine roots, they are placed outside the house in the cold, and warmed at great expense of material and labour. By planting the roots inside the house we utilize heat, improve the health of the plants, insure better produce, and avoid numerous failures which have their origin in our present most unnatural modes of treating the Vine and some other plants; we also obtain all the bottom-heat the Vine needs for making a healthy growth and furnishing a good crop of fruit.

D. T. FISH.

Fruit Protectors.—The cheapest and best of these I ever employed was a tame hawk. The summer before last it was tethered by the leg in the Strawberry quarter, with a large stone for a perch, and neither myself nor others ever saw a bird near the fruit. The blackbirds and thrushes got so accustomed to the sight of him that they perched on the wall a bit off, flapping their wings, and uttering that peculiar "te-whip" which they often give in the presence of danger; but they ventured no nearer. The hawk was tame, but never familiar with anyone, except a black cat, which had been brought up in the same basket with it. It was fed with birds caught in the net on the Gooseberry quarter, and it made uncommonly short work of them, but did not deign to pick the bones, which the cat, in a general way, polished off. The hawk, which was singularly timid when it got dark, was last winter killed by a rat, during the night, in one of the greenhouses where it took shelter.—J. S. W.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Free-bearing Pears.—In Mr. Wildsmith's excellent list of these, I was rather surprised to find Bergamotte Espéren placed second. Does it not come gritty at this time, or is this the effect of its stock or position? I have seldom met with it at all equal to Winter Nelis. I quite agree with Mr. Wildsmith in his high estimate of the latter Pear; it is simply exquisite. Mr. Wildsmith's other notes are also most interesting and useful, though situation and soil may cause me to think less of Thompson's and Knight's Monarch than he does.—D. T. FISH.

Winter Strawberries.—Are these, about which some discussion has lately taken place, considered early or late fruit? Some varieties are especially well adapted for producing a second crop, while others seldom show a single fruit. In December last there were many green fruits on our last season's forced plants, but I am doubtful if they would ever have become useful for dessert, as Strawberries, if grown and ripened in the absence of sunlight, are but indifferent at best as regards flavour. I find the first week in March to be as early as we can commence our regular Strawberry season—that is, with fruit possessing a really good Strawberry flavour.—J. GROOM, *Henham*.

TREES AND SHRUBS.

PAULOWNIA IMPERIALIS.

THIS is a beautiful large-leaved tree, and one well adapted for lawn decoration in places where it will fully develop itself. In appearance it resembles the Catalpa, and, like it, flowers profusely during the spring and early summer months. The flowers, which are borne in terminal panicles, are sweet-scented, and resemble those of a pale blue Gloxinia. In France it grows to a large size; the largest which I have seen there would be some 50 ft. high, with a trunk 6 ft. in circumference. Unfortunately the flowers are apt to get nipped by late spring frosts, and the season must be very favourable for them to get properly developed. In Paris, the Boulevard des Italiens was lined with this tree, and was so, if my memory serve me rightly, since the war, in 1874. It seeds freely, and plants of it raised in that way may be used in beds as fine-foliaged

Paulownia imperialis.

plants, in the same way as the Ailantus is now used. The seed, however, is useless after it is a year old. No doubt there are many places in this country where it could be made to grow into a large tree, provided a little protection in its first and gross stages of growth were given to the trunk by twisting a piece of shading or netting around it from early winter till May, and placing some short litter over the roots.

Floors Castle, Kelso.

H. KNIGHT.

HOLLY IN FLOWER AT CHRISTMAS.

At the last meeting of the Botanical Society of Edinburgh, Mr. M'Nab called attention to the great scarcity of Holly berries on the trees and bushes round Edinburgh. "Since I last addressed you," he said, "I have received numerous letters on the subject from correspondents in various parts of the kingdom, from which I learn that the scarcity has been general, and that different causes are assigned for it. The only places where an abundant supply of berries has been noticed were in some of the Highland districts, such as the Trosachs and Loch Katrine, and also at Loch Ard in Aberfoyle. One correspondent at Ranelagh, near Dublin, states that on sending to the garden before Christmas for sprigs of Holly with berries on them, few could be got, but instead of berries several of the trees were found to be covered with clusters of white and cream-coloured flowers. The cause assigned for this early blooming was that the blossoms must have been destroyed by snow and frost on April 14 last year. During the past summer many of the plants had nothing to do in the way of maturing fruit, so flower-buds have been formed which opened prematurely. What effect this early blooming will ultimately have on the Holly, another year will tell. On looking over the Holly bushes now in the garden, I find abundance of young flower-buds, but so backward that no flowers will be expanded for months to come. Therefore there is a fair appearance of fruit for next Christmas, if no

untimely frost should occur. Some allege that the late wet autumn had much to do in causing the berries to fall off while in a green state. The wet may have been the cause in some places, but here they were not in such quantities as to fall. The few which did ripen are those which must have been in the bud condition, and perhaps partially sheltered at the time when the general bloom was destroyed."

Cause of the Scarcity of Holly Berries.—Whilst the dearth of these is being discussed in THE GARDEN, it may not be out of place to direct attention to the fact that already there is promise of an abundance of bloom on the Holly next spring. As regards the hypothesis put forth by Mr. Darwin (see p. 40), it will be well if some of your readers will take note of the prevalence of bees or otherwise on the Holly in their respective localities during the blooming season, and also the results as regards berries. In the meantime I agree with Mr. Fish that bees can have little or nothing to do with the matter. Last spring we had a profusion of blossoms on all kinds of hardy fruits, but how lamentably short was the crop! To look for a large yield of fruit under the circumstances was natural, but it should have been recollected that two heavy crops of hardy fruits never follow in immediate succession. The failure, nevertheless, was mainly ascribed to frost, but it is obvious that, even had that influenced the blossom, the failure would not have been so entire. Just so with the Holly. Some trees that bore light crops the previous year have produced abundance of fruit this season, and yet all were equally exposed to frost. Is it not probable that a previous heavy crop of fruit so exhausts the reproductive powers of the tree for the next season that the floral organs are deficient in fertility? This is a possible fact that might have escaped the attention of even such an acute observer as Mr. Darwin.—D. A.

Tarred Trees v. Rabbits.—Tar extracted from the woods used in the making of gunpowder in the mills at Honnslow is commonly employed in this locality for the purpose of keeping rabbits and hares off fruit trees. This tar, which is of course a vegetable product, somewhat resembling Stockholm tar, is warmed over a fire and then ladled out into cans or pots—a little oil of any cheap kind is added to keep it from becoming too sticky—and then it is applied to the stems of the trees with a brush. An active man can run over many hundred trees in a day. A very small portion suffices to keep off rabbits, as the smell is of itself almost enough. This tar has been applied to young trees here for several years in succession, and there is no evidence that any injury results from its use.—A. D., *Bellfont.*

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Standard Cotoneasters.—Your correspondent "A." (p. 15) states that Cotoneasters form good standards on the Common Thorn. We have a pair that were budded on the Hawthorn five years ago, and they have now beautiful heads of drooping branches, which, when laden with berries, form very interesting objects; they are on 3-ft. stems, and make excellent plants for borders.—J. Groom, *Hendon.*

Two-year-old Holly Berries.—I see recorded in a provincial paper a case in which two Hollies carried their fruit for two years. The berries, which were red and ripe last winter, are said to be still upon the trees red and green, and to have been so all the past summer. This is a singular circumstance—has it been noticed before?—J. S. W.

The Best Lilacs.—M. C. Ballet recommends the following as the kinds most worthy of culture among the varieties raised in recent years. He has observed more than fifty kinds growing in his garden, and among them he considers there are twenty good ones. The undermentioned, however, are best of all; viz., *Aime Mœquet's*, *Blanc Virginal*, *Carné a Grande Fleur*, *De Laval*, *De Crocels*, *De Trianon*, *Gloire de Moulins*, *Madame Kreuter*, *Philemon*, *Ville de Troyes*, and *Sauge*.

Tilia europæa dasystyla.—Every one knows the grand form and symmetrical growth of the European Linden, planted as a shade tree all over the land. Imagine equally perfect forms in the variety *dasystyla*, combined with young wood of the richest tints of yellow and red, and a wonderful, shining, dark gloss of leaf contrasting strongly against the yellow twigs. To these are to be added the quality of persistent retention of foliage. Long after the early browned and rusty leaves of other Lindens have entirely disappeared, this variety (according to Mr. S. Parsons in the "Country Gentleman") remains its fullest perfection. For all practical purposes, such as transplanting, resisting stress of weather, &c., it justly claims equal rank with its parent, and is quite as easily propagated.

Pinus insignis in Co. Dublin.—Having recently seen a descriptive note in your journal of *Pinus insignis* at Mount Shannon, I was induced to measure a specimen here which I planted out of an 8-in. pot in the autumn of 1854, in one of the Punctums. I find the following are the dimensions of it:—Height, 87 ft.; circumference of the stem at 4 ft. from the ground, 7 ft. This specimen is well furnished with branches to the ground; its growth this season measured 2 ft. 3 in., and it is in perfect health. I have planted several other trees of this variety from this to time, which are making equally rapid growth.—Mr. ROBERT, in "Garden of the World." The specimen above mentioned grows at an elevation of about 200 ft., and in a cool position. It is thus proved to be peculiarly fitted for moist hill-districts, though so often a failure in low ground.

THE INDOOR GARDEN.

PREPARATION OF LILY OF THE VALLEY FOR FORCING.

THIS beautiful little Lily, despite the preference that exists for new plants, both hardy and exotic, still holds a prominent place in our gardens, and thousands of its lovely spikes of bloom find their way to Covent Garden Market at this season of the year. No flower is more in demand for decorative purposes, both in pots and boxes, and also in the shape of cut flowers during the early spring months than the Lily of the Valley. It is a most accommodating plant; it can be had in bloom from New Year's Day until it is developed in a natural form in our open borders. In order to flower early it may be forced in pots, pans, boxes, and indeed in a variety of ways; but for the embellishment of glass houses, corridors, or sitting rooms, it is best forced in pots or pans. This little Lily, native though it be, is rather capricious as to its likes and dislikes, so far as locality is concerned. In some situations it grows with the utmost freedom, and almost in any kind of soil, whilst in other places it refuses to thrive even in any compost. Where it is found growing the most freely, in woods and plantations, the soil is generally of a sandy character, enriched by fallen leaves, a circumstance which should give us a clue to its cultivation in gardens. Good sandy loam will be found an excellent soil for it. I have seen it grow freely and bloom profusely on a south border in rich kitchen garden mould; but when growing in a sunny situation its foliage soon dies. In the open air, the most suitable position for it would be one with a western or eastern aspect, or even a northern aspect would be more congenial to it than one facing the south. In its natural habitats it is often found growing luxuriantly under the shadow of the common Bracken, showing that a shady situation is that which it prefers. When planted in borders the natural soil should be dug out 1 ft. or so deep, and the bottom should be well drained; then fill up with some light sandy soil and rotten leaves in about equal quantities. Any one having only a small patch of this Lily may readily increase it by taking up the roots now and dividing them, but when thus divided there will not be much bloom for a year or two. In taking up and renewing a bed, in order to have plenty of flowers the present and following years, the roots must not be much separated; on the contrary, take them up in little patches and plant them about 9 in. from each other. In forming a new plantation where roots are no object, they may be distributed over the ground about 3 in. apart. If, at the time of planting, each cluster be reduced to five or six crowns, and they are planted in rows 6 in. apart, with the rows 1 ft. asunder, in three years they will be in fine condition for forcing. When they are required to bloom early in January, the roots must be potted as early in autumn as possible, or quite as soon as the foliage begins to decay, which should not be later than the end of October. In potting, good drainage is required, and, whether grown in pots or pans, they should just be sufficiently large to hold the roots, and no more. A light, sandy soil, with leaf-mould freely added to it, and liberal supplies of water, will be necessary. After potting, they should have a gentle watering, to settle the soil about the roots. The best situation for them afterwards is a cold frame or pit, in which the pots should be plunged 2 in. or 3 in. over the rims in Cocoa-nut refuse, spent Hops, tan, sawdust, or leaves. When they are started into growth they should be placed in the dark till the bloom-stalks and leaves are several inches high. A Mushroom-house, where one exists, is the most suitable place for them. When they are about 4 in. high, they must be exposed to light by degrees. If the pots could be plunged in a bottom-heat of 70°, whilst that at the top, close to the heads, was merely 55° or 60°, success would be made certain. When brought to the light, an empty pot should be turned over them for a few days until the foliage assumes its natural green colour. Thus treated, the flowers will be produced on a robust tall stalk, very different from those forced from the first in light, which dwarfs both flower-stem and foliage. Of course this extra care is only necessary in the case of plants forced very early. Towards spring all these precautions are of

less moment. When the blooming season is over, it is a great mistake to turn the plants out-of-doors, and expose them to cold winds and keen frosts. Having started into growth, if we wish them to bloom a second and a third year, we must keep them growing. A position as near the glass as possible, either in a Peach-house or late Vinery, will suit them perfectly. When properly cared for after blooming, they will flower the next and following years as the first. Lilies of the Valley may now be bought in clumps or patches sufficiently large to fill a 7-in. or 8-in. pot with masses of roots, and if properly managed they will each produce about two dozen spikes of bloom. When these plants, which are imported from France, Germany, and Holland, have been gently forced for a year or two, they will bloom in January with very little forcing, that is, if the bulbs have been properly ripened the previous years. When they have to be taken up from the open ground for forcing, without undergoing a previous preparation for the purpose, only the large, firm bulbs should be selected, and these must be closely packed in the pots: and if they receive a good bottom-heat at first, with a lower atmospheric temperature, they will come all the finer, though it will require the very best of our home growth to equal the clumps that come from the Continent, and which are of such advantage to us in winter and spring. R.

THE CAMELLIA AND ITS CULTURE.*

CAMELLIAS have been known and cultivated in England for nearly 150 years, and, in addition to imported kinds, many excellent varieties have been raised from seeds. In the work of raising seedlings England stood first for many years, Germany followed, and latterly the Italians have been very successful raisers of fine Camellias. A Camellia plant in perfect health should have glossy, dark green leaves, and the bark of last year's growth should be clean and shining. Camellias cannot be treated as many other plants are, inasmuch as they are generally wanted in flower five or six months out of the twelve, and if put into a warm conservatory before their flowers are expanded, they commence growing before they have done flowering, and the consequence is they get no natural rest. If they have begun their growth in the conservatory, they should remain in it or in a similar temperature until it is completed, otherwise they receive a check, and although they may only have made 1 in. of new wood, they will form clusters of flower-buds, and even though disbudded the flowers will be small. But if they can be taken to a cold greenhouse before growth has commenced—no matter how cold it is, so long as frost is excluded—and if they can be kept somewhat dry at the root so as to give them a season of rest until their growing season comes round, the blooms will set strong and vigorous. The longer they are kept in this comparatively cool, dry state the more vigorous they will grow, and the stronger they will be to produce a heavy crop of flowers. They should be kept in this cold and comparatively dry state, with as much air admitted as the season will allow, until every bud is pushing. After that a different mode of management must be adopted, and advantage must be taken of a fine day to examine the state of the drainage. Undo all the crocks that adhere to the ball and re-arrange them carefully; a thin layer of fresh Moss should be put over them, reduce the ball, and replace the deficiency with half good loam and half sheep manure. Give them a good watering, but instead of abundance of air, as heretofore, keep them rather close, not opening the lights till after breakfast, and shutting them down again early in the afternoon. If the sun be at all strong the glass must be shaded, for the young leaves are extremely liable to be scorched while in a young and soft state. When the weather is warm they should be syringed twice a day, a little before noon, and again when the sashes are closed down for the day. This will keep the atmosphere of the house damp, and a genial vapour will arise in the afternoon from the confined heat. In about six weeks, if all have gone on well, they will have finished their growth, and more air may then be allowed, but still they should be shaded, and the atmosphere kept warm and moist

until their flower-buds are well set, which may easily be known by their being so much more prominent than the wood-buds. The plants will have been rendered so excitable by the foregoing treatment that if continued much longer they will be starting into fresh growth, and instead of flower-buds shoots will be formed. As regards soil, Camellias like a good, fibrous, yellow loam. When re-potting, great care, as has been stated, should be exercised as to the drainage, for when they are coming into bloom, either in winter or spring, they require liberal supplies of water; and if the drainage be not perfect the soil becomes sodden, and the roots, notwithstanding their apparent strength, are very susceptible of injury. In potting, the soil should be made quite firm, and the plants should be kept a little close and shaded for a week or two afterwards; then give plenty of air night and day.

As regards the best means of renovating unhealthy plants, the first step is to ascertain, if possible, the cause of the evil, for without some knowledge as to this we can only proceed at random. In nine cases out of ten, failures experienced in the cultivation of this and similar plants arise from the roots being in bad condition. In the first stages, many of the fibres may have perished without any visible change being observable in the leaves or branches, for Camellias do not die off at once, like many other plants, but struggle on for months, and even years, before they get beyond recovery. The first symptoms of bad condition only become manifest on examination, at least until the growing season comes round, for then enfeebled roots produce a stunted growth and a profusion of flower buds. Now is the proper time for arresting the progress of the disease, and, instead of allowing the plants to spend their remaining strength in producing a heavy crop of bloom, let every bud be rubbed off. Thus the strength and substance necessary for maturing a crop of diminutive flowers will be expended in invigorating the wood-buds for next season's growth. If the roots in the meantime have been judiciously treated, the chances are that they will be in a fair way to support a healthy growth next year, and if so, the plant may recover; but to insure a permanent state of health it should not be allowed to flower too freely for a year or two. The best way of renovating diseased roots is to shake as much of the old soil from them as can be done without breaking them, or, better still, soak the ball well, and then rinse the soil away from them, as it is difficult to remove the soil without breaking the fibres; then cut back all that are dead at the points, and also any that appear in any way cankered or unsound, re-pot in the smallest-sized pot that will hold the ball, using the compost already named, and taking care to secure good drainage, and for the next two months keep the plant in a close, cold house with a damp atmosphere, giving it as little water as will keep the soil from becoming too dry. Camellias, when in good health, require liberal supplies of liquid manure, but it should not be given before the flower-buds are formed. Aphides sometimes attack the young shoots, but these can easily be got rid of in the usual way. A small white scale also occasionally infests them, and when that happens cleanse them with water strongly impregnated with soap, applied by means of an old tooth-brush.

Cut Flower Buds of *Eucharis amazonica* Opening in Water.—Early last autumn I shifted a quantity of plants of this *Eucharis* into fresh soil and larger pots; in a week or two afterwards I found that they had pushed up several flower-spikes, and not wanting the flowers I determined to cut them off with the view of strengthening the plants. One of the spikes, a little more developed than the rest, after being thrown away was picked up by a little girl, who, admiring the peeping white in one of the buds, placed it in a vase on the mantel-shelf, and I was much surprised in about a fortnight after to find that one, the most forward bud, had expanded into a perfect flower. Shortly after another opened, and at Christmas a third, fully seven weeks after the spike had been cut; all the flowers were perfect, except a little paleness in the green stripes on the corolla of the last. These facts may perhaps be of service to those who have weak plants, for if the flower-buds be formed, they will certainly expand if cut and placed in water in a warm room with plenty of light. Mine were kept in a dark room, which will perhaps account for the want of colour in the last flower.—SANGUINEA.

* Read by Mr. SPREADBURY at a meeting of the Wimbledon Gardeners Mutual Improvement Society.

EFFECTS OF THE LATE MOIST AUTUMN ON EARLY RHODODENDRONS.*

The autumn of 1876 has been particularly unsuitable for ripening the flower-buds of many of these plants, which are generally lifted during the months of October, November, and December, for the purpose of subjecting them to artificial heat, and thus bringing them into flower during the winter season, both for conservatory and table-decoration. Rhododendrons, particularly the early-flowering varieties known and cultivated as the R. Nobleanum breed, are exceedingly useful for this purpose. They are lifted after the flower-buds have been formed, and are forced almost every year. Although many of those lifted last autumn were apparently well furnished with buds few of them seem to have been properly ripened, as scarcely any flowers have been developed. The scarcity of Rhododendron flowers at this season seems very general, particularly in the gardens and nursery establishments round Edinburgh, and I am inclined to think, from the high price of flowers quoted in Covent Garden Market, that the scarcity is not wholly confined to this district. Judging from the unnatural state of these Rhododendrons already experimented on, I have no hesitation in saying that the number of imperfect blooms has in a great measure been caused by the unusually long want of sunshine during the autumn and winter months, and the almost incessant rains experienced during that time. At this period, the effect is certainly very marked on all the early-flowering Rhododendrons, but what it will be on the late-flowering varieties, as well as on the blossoms of fruit-trees, both wall and standard, it is difficult to say. Rhododendrons as a rule, particularly if the buds be well ripened in autumn, and even under an ordinary clear sky, are generally much more easily forced into bloom than specimens put into heat, which have not been subjected first to a certain amount of autumn or winter frost. Even the frost of last November has had no effect on those already tried, the buds not being sufficiently matured beforehand for this purpose. Early-flowering Hyacinths, Tulips, and Narcissus, as well as many other plants, are also observed to be far from strong, probably owing to the late sunless weather experienced since they were subjected to heat.

J. McNAB.

Carnation Souvenir de la Malmaison.—This beautiful Carnation is neither so well known nor so much grown as it deserves to be; here it succeeds admirably. By layering 1 get vigorous plants to commence with: about the middle of July, when the plants have all flowered, I plunge them in their pots under a north wall or shady place, layer them in the usual manner, and in about three weeks they become well rooted. I pot the young plants into 18-sized pots, in soil consisting of three parts dry loam and one part rotten manure and rough sand. The weakest may flower in the above sized pot, but the strongest will require to be put into 32-sized pots before forcing has commenced, and until that time they should be kept in a cool frame. The temperature in the forcing-house should be from 55° to 65°. Thus treated, they may be had in bloom for several months in succession.—R. B. FULLER, Hillgate.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Pelargonium Marie Lemoine.—Among a hundred or more varieties of which I was well acquainted, new and old, this, according to "M. Les Banaux" is not surpassed. The individual flowers, of a delicate rose colour, as well as the truss, are the largest of their class. It is difficult to select a more beautiful one than Marie Lemoine when freely blooming. Every truss is useful a specimen. The leaves are large, crisp, and vigorous, while the plant is compact and valuable whether for the conservatory, window, or garden.

Camellia Buds dropping.—When I came to the gardens of which I now have the charge in August last, I found the plants in a bad state, some covered with mealy bug and brown scale, others with green fly, especially the Roses in the conservatory. The Camellias, on the contrary, were covered, from which I have thoroughly cleared them. Some of the Camellia buds are, however, dropping, and I have time and time again, for two months, touched the plants and redressed them. They are in the conservatory, in a temperature varying, as a rule, from 45° to 55°, but on Friday nights falling to 40°. On Christmas morning and on three other days I lamped them overhead, gently with the syringe, and my only regret is that I have not yet got the buds, which come gently down. I lamped them because I was under great heat and the atmosphere was dry. My own opinion is the buds are at fault, as in the case of some of the plants the buds are green, although the shells or outside is brown.—R. C. T., Chelsea.

The brown state of the buds is almost a certain indication that the plants are weak and in a bad condition—a circumstance quite sufficient to account for the buds dropping. In addition to this the pressure in the conservatory remains close when plants are so badly affected with it that it attacks the buds, frequently causes them to fall some time afterwards. Spraying overhead is not a good way of getting rid of the mealy bug, it is much better done by means of evaporating spirits on the pipes which should exist in numbers per square foot of the surface of the house, and which will continuously but imperceptibly keep the air in the room cool. Spraying overhead is not at all likely at the time I speak of, and the buds will drop off later in the season, when growth is at an end, and, of course, it would not likely have that effect.—T. BARNES.

PLATE LVII.

HYBRID PERPETUAL ROSE.

COMTESSE DE SERENYE.

Drawn by H. NOEL HUMPHREYS.

First amongst the many worthless new Roses that have been proclaimed of recent years upon English Rose growers by their French names, the subject of the present plate stands forth as an agreeable exception to the rule. It was introduced by M. Lacharme, of Lyons, in the autumn of 1874, and I find, on reference to his prospectus, that he sent out two other kinds at the same time, viz., Hippolyte Jamain and Souvenir du Baron de Semur. The former of these has already proved itself a real acquisition, but the latter, although a fine dark flower, is of such weak constitution and growth, as to be totally unfit for English gardens. The flowers of Comtesse de Serenye when produced out-of-doors may be described as delicate pink in colour, shaded with rose, and inclining to salmon in the bud. They are of large size, very full, and possess all that perfection and symmetry of form which has hitherto been considered almost a special characteristic of the variety Comtesse de Chabillard. The plant succeeds well grown on either the Manetti or Brier stock; the growth is vigorous, and the habit and constitution good. Under glass the flowers are rather paler in colour than when grown out-of-doors; but they retain all their other good qualities, so that for forcing purposes and pot-culture generally it stands unsurpassed among pale-coloured Roses. Although as yet comparatively new, it bids fair to prove itself valuable both for exhibition purposes and for garden ornamentation. The blooms will, however, require protection in unfavourable weather if their delicate colour is to be carried unsullied to the show room. There are two other varieties bearing similar names, and which must not be confounded with the one under description: they are Comte Alphonse de Serenye and Comtesse Vally de Serenye—neither of them possessing any great value. Amongst other good new Roses sent out at the same time as Comtesse de Serenye may be mentioned Hippolyte Jamain alluded to above, Antoine Mouton, La Rosière, Villaret de Joyeuse, E. Y. Teas, Star of Waltham, and Amélie Hoste amongst the Hybrid Perpetuals; and in the Tea-scented class, Perle des Jardins, Marie Guillot, Jean Daffer, and Comte de Sembui. ARTHUR W. PAUL.

INSECT FERTILIZATION AND CLOSED FLOWERS.

SINCE I object to erroneous quotations as much as Dr. Asa Gray or Mr. Meehan can, I should have written to you before this to correct the error—whether misprint or mis-statement, in my former letter, had I not thought it too obvious to mislead. I wrote, or thought I wrote, not Wistaria, but Glycine, and referred to p. 294 of the flora of North America. This was an error, since the close ally of the cleistogamous Glycine, Amphicarpea, is the plant there mentioned as cleistogamous; but I never thought of terming Wistaria cleistogamous. I much regret that Mr. Meehan should think me or Dr. Gray—for the charge applies equally—ungenerous because acting on the principles of a self-interest, and of an distrust. As we preferred trusting Mr. Darwin's observations when Mr. Meehan's conflicted with them. If, however, Mr. Meehan thinks I have done him an injustice, recognising the great value of his work, I most heartily apologise. As to the cleistogama, or closed flowers, I bear space, however, for a few remarks, based partly on Mr. Darwin's recent work. The necessity of occasional crossing laid down by Knight and Darwin was exaggerated by Hildebrand and Delpino, until Axell, a Swedish botanist, reasserted the limitations of the original rule. He first laid stress on these cleistogamous flowers, so named by Kuhn, and made one suggestion, at least, which seems important, viz., that heat, being evolved in flowering, would be economised by plants in a low temperature producing reduced flowers. As an instance, he gave Lamium amplexicaule. Mr. Darwin has well insisted on the point that adaptations to secure cross-fertilization by avoiding self-pollinization risk the entire fertility of the plant, whilst reproduction is of far greater importance than crossing. Thus it would be to the advantage of an insect-fertilized plant deprived of its insect visitants to produce self-fertilizing flowers. Nature, as we know by the facts of dichilism, diochamy, and dimorphism, often uses divers means for one end; so we find in some species entirely self-fertilized (because never opened) flowers on the same plant with others, which, I believe,

* Read before the Botanical Society of Edinburgh, Jan. 11, 1877.

secure an occasional cross, as in *Viola odorata* and *Amphicarpææ*; whilst, as Dr. Müller has shown, in other species two distinct forms occur in different localities, one normally cross-fertilized, the other normally self-fertile (though from their corollas I should imagine these latter to be occasionally crossed by insects). Perhaps we may see in the extreme plasticity of the corolla in *Viola tricolor*, which has only been in cultivation since 1687, a clue to its entire suppression in the cleistogone flowers of *V. odorata*. In this connection also I would refer to Dr. Müller's view as to the evolution of various forms of *V. tricolor* inhabiting different altitudes through their adaptation to different groups of insects.

G. S. BOULGER.

Cressingham, Reading.

HARDY CRINUMS.

It is probable that the South African *Crinum*s, at least those which grow in the latitude occupied by the hardy and half-hardy Iridææ, will also be found more or less hardy under favourable circumstances in England. I have only tested the capabilities of two of them as follows:—*C. capense* is truly hardy here at Welton (near the centre of our island), where it thrives, flowers, and produces seed in abundance under water round the margin of a pond. This and a paler variety called *C. c. fl.-albo* in the catalogues, were formerly to be had at 1s. 6d. a bulb, and might doubtless be had cheaper if a demand arose for them. The pure white variety is more tender and does not succeed in the pond. The variety called *C. riparium* is described as being of a richer purple colour, but my specimens raised from seeds of Herbert's plant do not differ materially from the normal form. *C. campanulatum*

Crinum aquaticum (campanulatum of Herbert).

(Herbert) syn. *aquaticum* is hardy also, but perishes under water treatment of any kind, for which reason Herbert changed the name as propagating an error. I have never flowered it, as it is one of the many bulbous plants in which the flowering is impeded by the production of interminable offsets. *C. revolutum*, another possibly hardy sort, is not, I believe, now in the country; it very much resembles *C. campanulatum* in foliage, flowers more freely, and does not expend itself in offsets. I may remark here that the *Amaryllis revoluta* of the Cape bulb sellers is merely the *Belladonna Lily*. *C. variabile* is another small offset-bearing sort, said to be quite hardy. I have lost it, and do not think it exists in our collections. Several of Herbert's hybrids from *C. capense* proved hardy at Spofforth. Many of these were sent to India and elsewhere by him, and I suspect some of them have come back to us as new species. A large spherical bulb, occasionally received from the Cape and also from India, with long trailing scabrously-margined foliage, seems likely to be one of Herbert's crosses between *C. scabrum* and *C. capense*. There is another sort which is now and then received from the Cape closely resembling *C. capense*, but somewhat larger and not so hardy. It may be known by the brittleness of the bulb coats. I fear there is no chance of the Cape Coast family (*Ornatæ* of Herbert) ever proving hardy enough for open-air cultivation in our climate. I do not possess *C. Mooreanum*, which appears to give good promise as to hardness. *C. capense* is bold and handsome, and well worthy of cultivation as an aquatic.

R. T. CLARKE.

Welton Place, near Duventry.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Camellias are plants not at all difficult to manage, yet they are by no means always seen in a satisfactory condition. They cannot bear being dry at the roots, and when this happens, particularly at the time they are making growth, they become stunted, and the roots are weakened, the flower-buds falling without opening; this will also occur if the atmosphere be too dry, when they ought to be expanding. They must not, however, be over-watered.

Bedding Plants.—Now is the time to commence propagating bedding plants. If seeds of any of the Silver-leaved *Centaureas* be now sown in heat, and pushed well on, they will make fine plants by bedding-out time; they should be sown in shallow pans in fine soil, containing a little sand and well-rotted leaf-mould; let the seeds be only just covered with soil, and keep it slightly damp. If *Ageratums* have to be raised from seeds they should also now be got in; let these, too, have shallow pans filled to within 1 in. of the rim, with a mixture of equal parts of leaf-mould, fine loam, and a small quantity of sand; press the surface smooth and sow the seed, covering it with a little soil; let the pans be in a temperature of 50° or 55°, and as soon as the young plants appear give them plenty of light, or they will draw; it is better, however, to raise *Ageratums* from cuttings, as they cannot be depended upon to come true from seed. Golden *Pyrethrum* is best raised from seed, as propagated in this way the plants have not such a disposition to flower, and are finer than those obtained from cuttings or division; sown now in warmth they will soon be up, they can then be placed in boxes or pots. For carpet bedding, such subjects as *Alternantheras* and the crimson *Iresine Lindenii* are almost indispensable; their propagation should be at once attended to. Look carefully over all the stock of bedding plants to see that they are free from aphides; if any be found fumigate without delay. *Verbenas*, more particularly the white kinds, are very liable to the attacks of mildew; on its first appearance they must be dusted with sulphur. It will be well now to put the store plants of *Verbenas* in a little heat to cause them to push young growth for cuttings; 50° by night will suit them well; a few degrees more, however, will not injure them; let them be on a shelf or in some place where they will receive plenty of light, and keep them regularly supplied with water; an application of liquid manure once a week will be beneficial to them, and will cause the production of more cuttings. *Heliotropes*, *Lobelias* of the speciosa section, and *Ageratums*, should also be put in warmth, for if the cuttings be not soft and young they do not root so readily. *Pelargonium* cuttings, several of which have been placed in 5-in. or 6-in. pots, should not be too much crowded; unless they can have a temperature of 45° to induce them to form roots it is not advisable to pot them off yet. Look over roots of *Dahlias* and *Salvia patens* to see how they are keeping; if it be found that the old stems of the *Dahlias* are mouldy and wet they should be moved to a drier place, or very likely the eyes at the collar will die; but do not put them where there is enough warmth to cause them to start into growth. The old *Humea elegans* is very handsome, either grown as a pot specimen for greenhouse decoration or planted out; if those sown last summer have plenty of roots, shift them now into pots big enough to serve till planting-out time arrives. Should they be at all neglected in the matter of root-room, the bottom leaves will be injured, thereby ruining the appearance of the plants; give them good loam well enriched. Aphides must be guarded against, for if left for any length of time undisturbed they spoil the leaves. *Rhododendrons*, Double *Prunus*, Ghent *Azaleas*, &c., should at regular intervals be placed in heat to bring them into bloom. Employ sufficient care and forethought in this matter so as not to have a superabundance at one time with a corresponding scarcity at another.

Potting Soil.—Loam, peat, and leaf-mould ought to be got under cover and spread out in open sheds, so as to have it in a sufficiently dry state for use when the time for potting arrives. The exceptionally wet weather we have had for some time will have made it doubly necessary to see to this at once.

Frames.—Consequent upon the mildness of the season more air must be given to the occupants of frames, or they will be so tender that they will be very susceptible to frost when it comes. This applies to plants as well as to Lettuces, Cauliflowers, &c., the latter of which are liable to button—that is, form small, premature, useless heads—if they do not receive enough air. Another Mushroom-bed may now be made similar in materials and preparation to the last. A good look-out should be kept for slugs, for the present wet, mild weather is extremely favourable to these unwelcome visitors.

List of Vegetables.—The innumerable varieties of seeds offered in catalogues are a source of great difficulty to amateurs in knowing what to select. When first "The Amateur's Garden" found

a place in THE GARDEN, a list of vegetables was given for the assistance of amateurs. I have thought it will be of service to again give one, with the addition of a few more varieties of sterling merit:—*Peas*—Saugster's No. 1, William the First, Dr. Maclean, Cullingford's Champion, James' Prolific, which is the best of the Veitch's Perfection Type, Emperor of the Marrows, and Ne Plus Ultra. *Potatoes (Kidney)*—Myatt's Ashleaf, Veitch's Improved Ashleaf, and Lee's Hammersmith Kidney; *Round Kinds*—Early Oxford, York Regent, and, for the latest, Paterson's Victoria. *Cabbage*—Cocoonant and Entfield Market. *Savoy*—Dwarf Green. *Carrots*—Early Red Horn and James' New Scarlet. *Cauliflowers*—Early London and Veitch's Autumn Giant. *Celery*—Cole's Crystal White, and Wilcox's Dunham Red, which has appeared under the name of Leicester Red; it is also very nearly alike to, if not quite the same as Williams' Matchless Red. *Brussels Sprouts*—Roseberry and Imported Dwarf. *Broccoli*—Backhouse's White, Snow's Winter White, Veitch's Self-protecting Autumn, Williams' Alexandra, and the old Purple Sprouting, which is one of the most useful, finest-flavoured, and long-producing vegetables grown. *Kale*—Dwarf Green Curled and Cottagers'. *Broad Beans*—Mazagan, Early Long-pod, and Seville Long-pod. *French Beans*—Negro, Paris, Red Flageolet, and Osborn's New Forcing, for pots. *Runner Beans*—Scarlet. *Beet*—Dell's Crimson, White Silesian. *Cress*—Plain-leaved and American. *Cucumber*—Rollisson's Telegraph. *Leek*—Musselburgh. *Endive*—Green Batavian and Green Curled. *Lettuces (Cabbage)*—Wheeler's Tom Thumb, Neapolitan, and Hammersmith Hardy Green; (*Cos*)—London, Victoria, and Black-seeded Bath. *Parsnip*—The Student. *Parsley*—Myatt's Curled, and Veitch's. *Onions*—Nuneham Park, James' Long-keeping, Brown Globe, Brown Tripoli, and The Queen, a small, very early kind. *Radishes*—Short-topped Frame, Red and White Olive-shaped. *Spinach*—Round and Prickly. *Tomatoes*—Hathaway's Excelsior and Orangefield. *Turnips*—Early White Stone, Red-topped American Stone, and Chirk Castle; this latter is a black-skinned excellent variety.

Ground-work, &c.—Whatever new ground-work or alterations are not yet finished should, notwithstanding the wet state of the ground, be pushed on without delay, so as to get them completed as quickly as possible; for, should frost set in, it may last until the season for planting with a reasonable chance of success is over, for we must by no means fancy that the time for severe weather occurring is past.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

January 22.—Sowing some pots of *Agrostis nebulosa* and *pulegiella*; also a few rows of Little Gem Peas close to Peach wall. Potting plants in Lycaste-house; also *Masdevallias* and *Selaginellas*. Potting off young plants of *Pentas* and *Scutellaria*. Re-potting plants of *Calceolaria aurea floribunda* into 8-in. pots for spring flowering. Putting in cuttings of *Nasturtium*, *Monochaetum*, and *Heliotrope*. Putting in *Vivae* eyes. Planting remaining fruit trees, and filling another pit with Potatoes from pots. Putting in plants to force for stands and cut flowers; also another batch of *Asparagus*. Shifting the *Humeas* into 10-in. pots. Putting *Asparagus* tops over Peas just peeping aboveground to keep off sparrows, and to ward off frost; owing to the lightness of this material the Peas grow right through it. Painting Apple and Pear trees with three parts lime and one part soot, mixed with water to the proper consistency. Examining basketed *Dendrobiums*, and removing any decayed material. Watering Cucumbers, but taking care not to get them too wet. Sorting Apples and Onions. Making-up hotbeds for Lettuces, Cauliflowers, Carrots, Radish, tree Carnations, and Violet cuttings. Turning manure for Celery. Disbudding pot Vines. Keeping second Peach-house just coming into flower at 55 at night and 60 by day. Dipping *Cinerarias* into Tobacco-water for fly.

Jan. 23.—Digging Rose-garden borders; also land for succession Peas. Sowing a border of Parsley, Carrots, Radishes, Alexandra and Paris Cos Lettuces, and Walcheren Cauliflower in frames. Potting some *Taberones* and placing them in heat to force. Putting in cuttings of *Coleus*, *Crotons*, and more *Alyssums*; also a little Musk in slight heat weekly. Nailing Roses on walls. Putting some red worsted over Peas that are coming up to keep off birds; also sooting Gooseberries for the same purpose. Giving pot Vines some Standen's manure. Mixing manure for second crop of Potatoes. Throwing some rough strawy manure into a heap for another Mushroom-bed. Finishing pruning Gooseberry trees. Thinning plantations. Keeping first Strawberry plants a little drier as blossoms are expanding.

Jan. 24.—Putting in cuttings of *Ageratum* and *Solanum capsicastrum*; also old plants of *Achyranthes*, *Alternantheras*, *Heliotrope*, and *Mesembryanthemums* into warm *Vivary* to induce them to furnish cuttings. Planting out Potatoes from pots. Getting all Roman Hyacinths in flower into greenhouse. Putting Kidney Potatoes into hampers to sprout. Cleaning scale off *Camellias* and one or two other plants. Making up hotbed for Tree Carnation cuttings. Loosening shoots of Peach trees on wall ready for pruning. Clipping Privet hedges.

Jan. 25.—Digging all vacant ground. Sowing Advancer and Laxton's Alpha Peas, Long-pod Beans, some Dutch Turnips, and Campbell's and Emerald Melons. Potting Mrs. Pollock *Pelargoniums*. Shaking out and re-potting *Daturas* and *Erythrinums*. Putting in more cuttings of *Salvia patens*, *Fuchsias*, *Nepetas*, *Alyssum*, *Agathas*, *Achyranthes*, and *Coleus*. Planting Seakale for forcing; also Potatoes as fast as they are ready for planting. Getting soil in to warm for potting Beans. Examining *Pelargonium* pits. Tying Pillar Roses. Sponging *Phalaenopsis* with Fowler's Insecticide to kill thrips. Giving first Hauburgh-house a good watering and dressing it with bone-dust. Forking amongst Gooseberry trees, giving them a sprinkling of guano. Removing suckers from fruit trees. Disbudding Muscat Vines and thinning the bunches as soon as ready. Keeping second Peach-house in which buds are swelling at 55 at night. Giving increased air to *Vineries* when they reach 90° so as to prevent their exceeding 95°, being careful to shut off fire-heat as much as possible. Plants in flower:—Yellow and other Roses, scarlet Van Thol and double Tulips, *Crocuses*, *Mignonette*, *Deutzia gracilis*, *Monochaetum eusifolium*, *Tydaes*, *Begonia incarnata*, *Lily of the Valley*, *Thyracanthus rutilans*, *Primulas*, *Azaleas*, *Dielytra*, *Hyacinths* (red, blue, and white), *Daphne indica*, *Calla aethiopica*, *Cytisus Attleiana* and *cavariensis*, *Cinerarias*, *Camellias*, *Acacias*, five kinds of *Epacris*, *Erica gracilis autumnalis*, and *E. hyemalis*.

Jan. 26.—Sowing Golden Feather *Pyrethrum*, *Centaurea argentea*, and more *Mignonette* in pots. Potting *Kalosanthes* into large 60-sized pots in very sandy soil, and placing them on south side of greenhouse. Potting and basketing *Dendrobiums*. Potting 500 Ash-top Potatoes. Striking cuttings of *Dracena terminalis* in strong bottom-heat. Planting more Potatoes in pits; also Ash-leaved Kidney and Myatt's under Peach wall. Fumigating East Indian Orchids to kill thrips. Liming and sooting the Gooseberries and Currants. Manuring borders in Peach-house. Preparing cradles for hardening bedding material. Inarching a Muscat Vine with Royal Ascot.

Jan. 27.—Sowing *Cyclamen* seed and putting it into cutting pit; also *Auricula* seed, and putting it into greenhouse; likewise a few Tripoli Onion seeds in heat, and Red and White Celery under glass on a manure bed. Potting *Gardenias*. Dividing Maiden-hair Ferns, and putting them into 60-sized pots. Potting some autumn-struck *Fuchsia* cuttings. Layering Tree Carnations. Re-arranging *Orchid*-houses. Putting one-year old Vines in first *Vivary* to break. Shifting some *Rhododendrons* into peat and sand for forcing. Nailing *Apricots*. Covering Celery with straw to protect it from severe frost. Watering under pipes in East Indian *Orchid*-house twice daily, and syringing the plants early in the afternoon. Keeping Strawberry-house dry where plants are in bloom. Top-dressing Orange trees with half manure, half loam; also *Lilacs* and *Laburnums*. Making-up Potato beds for frames. Putting soil in to warm for young *Cucumber* plants, and getting leaves and other fermenting material in pit ready for them. Making second Strawberry-house ready for plants.

Orchids.

Many *Dendrobes*, particularly the knotted-stemmed varieties from Burmah, will now be starting into growth, but notwithstanding that the cultivator must not be tempted into giving them a too copious supply of water or too high a temperature, or the young shoots will get ahead and the flowers will be lost. The plants should be kept moderately dry, cool, and in an airy situation until the flower-buds are well advanced, when the maturing of the growth may be attended to without risk. That most lovely of all the *Dendrobiums*, *D. Wardianum*, very frequently makes growth about 1 in. in height at the latter end of the summer, immediately after the mature growths have ripened off and at the commencement of the resting season; but if the plants be treated as resting plants, these premature growths will remain in the same condition for months until the growing season arrives, when they will push away freely. In consequence of the deficiency of sunlight for some time past, *Orchid* blooms have been slow in opening and are deficient in colour; but it is better to allow the plants to remain in their respective houses and wait patiently for the flowers to open than to endeavour to force

them into blossom by placing them in a higher temperature. Well-advanced buds are often lost by a sudden change of that kind, and even when they do open, when so treated they do not last nearly so long as if allowed to progress more gradually. The colour of the flowers may be heightened, and their opening promoted by placing the plants on inverted pots, and setting them on the lightest side of the house. The present is a good time to re-pot the cool-house *Odontoglossums* from New Granada, but none of them should be potted for the mere sake of potting them. Any that are doing well, and that are in good material, with the Sphagnum Moss growing over the top, should have the pots cleared of any green deposit that may be on them, but the plants otherwise should be undisturbed. The *Odontoglossums* should be carefully potted into pots filled with clean drainage almost two-thirds of the way up in a mixture of equal proportions of fibry peat and living Sphagnum. Where the plants are unhealthy and have but few roots, it is a good plan to cover the back pseudo-bulbs about one-third with the material used in potting, leaving the base of the first pseudo-bulb just above the surface, so that the young growth may not be obstructed. Most Orchids dislike any of the pseudo-bulbs being partially covered, but these seem to be exceptions to the rule, for one frequently sees plants of *Odontoglossum Alexandræ* which have lost the leading growth push new and strong growth from the back pseudo-bulbs 1 in. or more below the surface.

JAMES O'BRIEN.

COTTAGE GARDENING.

Herbs.

NO GARDEN, however small, can be said to be complete without its bed of Herbs, which are indispensable for flavouring purposes. With the exception of Parsley, Herbs are best grouped together in small patches in proportion to the demand, but yet at the same time each patch should be kept distinct. To keep them in strong, vigorous condition, they should be renewed by division, and in a few cases by seeds or cuttings about every two or three years. Some kinds, if they stand too long on one piece of ground, lose their vigour, and the winter, if severe, has more effect upon old plants than young ones, and may sometimes, by killing them off, occasion a scarcity; but where the plantations are frequently renewed this seldom or never occurs. Herbs are not at all particular as to soil or aspect, but one or two kinds, such as Tarragon, should not be planted in wet, cold soil if it can be avoided. From March to the end of May is a very suitable time for putting in cuttings, sowing seeds, or dividing the roots, and if called upon to speak more exactly, I should say get all such done in April if possible. The cuttings or slips—as they will succeed well if slipped off with a heel—may be planted with a dibble, and of course should be planted firmly. In planting cuttings at all times and in all places the length of the cutting should be considered, and the hole only made deep enough for the base of the cutting to rest on the bottom. Inexperienced planters often unthinkingly practise what is termed “hanging” when planting either plants or cuttings with a dibble; that is, they make the holes deeper than the length of stem, and, consequently, the roots of the plant or the base of the cutting, as the case may be, hang suspended in the hole, and cannot obtain a sufficient grasp of the soil to become quickly established, and often perish in consequence. Of the Herbs that are commonly used for flavouring purposes, and which are indispensable, are Thyme (two varieties, Common and Lemon), which may be increased either by seeds or cuttings or division of the roots; Sage (Green and Red), which may be propagated by seeds and cuttings. Of Mint, several varieties are grown, but the Spear-mint is most useful, and is increased by division and by cuttings with a bit of root attached in spring or early summer; it will grow in any position, but improves by being transplanted occasionally. Fennel may be increased by seeds and division of the roots, and Winter Marjoram mostly by division. The following also are not unfrequently found in gardens, and are often used to make cooling drinks and for medicinal purposes, viz., Rue, Horehound, Hyssop, Lavender, Balm, Wormwood, and Rosemary, all of which may be increased by cuttings and seeds. Camomile is best propagated by division of the roots, and it should be frequently transplanted in firm land. Amongst Herbs that are highly esteemed for flavouring purposes in large establish-

ments, and that are usually raised from seeds in spring—frequently assisted by artificial heat—may be mentioned Basil (Bush and Sweet), Summer Savory, and Sweet Marjoram. They should be sown, if no hotbed be at hand, the first week in May in light, rich soil in a warm, sunny place, be shaded and kept moist, and the young plants thinned out to 4 in. or 6 in. apart. If a small space in a frame or hotbed can be spared, sow a few seeds in a pot or pan early in April, harden the young plants off, and plant them out in May. By this means the plant will gain an early start. Chervil may be sown thinly in March, again in May, and again in August. All Herbs that require to be dried for winter use should be cut just as they are coming into flower, and when quite dry, they should be tied in small bunches, and hung up in some open, airy building or shed, and when thoroughly dried preserved in wide-mouthed bottles or jars and kept close. Basil and Summer Savory are tender, and should be cut and dried before frost is expected. When Herbs are dried in the sun they dry too rapidly, and lose some of their strength.

Parsley.

Parsley should be sown about the end of February or the beginning of March on well pulverized land in drills 1 in. deep and 1 ft. apart. It may either form an edging to another crop or occupy a bed or patch by itself. When large enough, thin out the plants to 4 in. apart, planting the thinnings elsewhere if necessary. Another small sowing should be made about the beginning of July, and be thinned out and treated the same as the early-sown lot. Some may think that in small gardens this late sowing is unnecessary. All I can say is, if I were compelled to depend upon one sowing only, I should sow at midsummer in preference to early in spring, and for this reason: Parsley sown early, and required to be gathered of a moderate size, becomes pretty well exhausted by the following spring, and hardly any precaution will prevent it rushing into flower before the new crop may be considered fit for gathering. But the crop from a midsummer or July sowing comes in at a season when everything is full of growth, and has a chance to get thoroughly established, and this is one advantage in favour of the permanency of the plant. Another and the main reason that may be advanced in favour of this time for sowing is, the plants have not the same tendency to flower and seed the following season. In fact, some plants do not seem disposed to flower, and even those that do, if the flower-stems be cut or pinched off before they make much progress, after a weak effort or two they give up the attempt to produce flower-stems and produce foliage instead in abundance. Any one who has hitherto depended upon the early spring sowing, and has found a difficulty in making the two crops meet, should try this plan. Strictly speaking, Parsley is a biennial, and, like other biennials, if sown after midsummer its season of flowering will be proportionately late; and many plants will miss flowering altogether till the following year, and this is a great advantage when plants are grown for their foliage alone. Some means of sheltering the crop should be devised and prepared before bad weather sets in. Straw hurdles or forked sticks may be placed round the bed on which other pieces are placed, when the whole may be lightly covered with Fern or dry straw.

E. HOBDAV.

How to Keep Bouquets Fresh.—There are various receipts for keeping bouquets fresh; some place them in moist sand; some salt the water in the vases, and others warm it; others, again, use a few drops of ammonia. My rule is to cool the flowers thoroughly at night. When warm weather has made Roses droop and their stems limp, I clip them a little, allow them to float in a marble basin full of very cold water, and in the morning they come out as fresh as if just gathered. All flowers, however, will not stand this treatment. *Heliotropes* turn black and fall to pieces under it, *Azaleas* drop from their stems, and *Mignonette* soaks away its fragrance. For these I use dry, cold air; I wrap them in cotton wool and set them on a shelf in the ice-chest. Flowers thus treated keep perfectly for a week with me, and often longer.—ST. NICHOLAS.

India-rubber Bands for Trees.—A New Haven company is making a new article to protect trees from worms. The invention is an India-rubber band with a single bristling row of brass pins set so close to each other, like the teeth of a comb, in the middle of the strip, that worms cannot crawl above it.

HISTORY OF THE GOURDS.

OF GOURDS, as we all know, there are several varieties, some of them beautiful in form and colour, others of very large size. Those which are commonly cultivated in England for food are the Pumpkin (*Cucurbita Pepo*), and the Vegetable Marrow (*C. Saccada*). Gourds were well known to the ancients, and we find them mentioned in several places in the Scriptures. They furnished models, according to the marginal reading of Knops (1 Kings, vi. 18), for some of the carved work in Cedar in the temple of Solomon. The Greeks appear to have been acquainted with several varieties of the Gourd, and they were to be seen at Athens with other products of the spring and summer, in the cold season of the year; for Aristophanes, in his "Seasons," speaking of the glories of that luxurious city, says:—

There you shall at mid-winter see
Cucumbers, Gourds, Grapes, and Apples,
And wreaths of fragrant Violets,
Covered with dust as if in summer.

* * * * *
There you may see fine Pumpkins joined
To the round Rape and mighty Turnip,
So that a stranger well may fear
To name the season of the year.—ATHENÆUS, b. 9, 11.

Diocles states that the best round Gourds are those grown near Magnesia, a town of Asia Minor. Euthydemus, the Athenian, in his book on vegetables, states that the seeds of the long Gourd were originally introduced from India. Pliny, in his "Natural History," tells us that Gourds resemble the Cucumber in their manner of growing, and he classifies them into two primary kinds; the first, which, from the rapidity of its growth, shoots upwards and creeps along the rough surfaces of walls and covers the roofs of houses in a very short time, he calls the "Roof Gourd." This kind, he says, bears a fruit of considerable weight, which is quite immovable by the action of the wind, although the stalks are of a remarkable thinness. This plant is considered by Fée to be *C. loogior* of Dodonæus and J. Bauhin, the long Gourd and other varieties probably of the Calabash Gourd—the *C. leucantha* of Duchesnes. The second kind mentioned by Pliny is that which creeps upon the ground, most probably the Pumpkin and its varieties. Gourds were held in higher estimation by the Romans than either Melons or Cucumbers, as they were employed for more useful purposes than the former fruits. They were considered a light, mild, wholesome food. The young and tender stalks used to be cooked and served up to table as a good dish. The fruits of the Roof Gourds were considered superior to those which crept on the ground. In Pliny's time large Gourds were used as jugs and pitchers in the baths; but long before that time he tells us they had been employed as casks for keeping wine. Nisander tells us that the ancient Greeks used to preserve Gourds by the following methods:—Cutting them into moderate-sized pieces and stringing them like beads to dry in the air; then smoking them. When wanted for use, each piece was well washed and put into the stewpan with various herbs, such as Cabbages, Endive, and dried Mushrooms. The Romans also preserved Gourds and Cucumbers, we are told, for some months, by putting them into brine. Pliny states that the seeds of the Gourd ought to be steeped in water before sowing, and the proper time for that operation should be between the vernal equinox and summer solstice, about the season of the festival celebrating the anniversary of the foundation of Rome called *Purilia*. The Roman cultivators used to force Gourds to grow into various fantastic shapes by putting them into moulds when quite young; thus we are told that they were made to resemble a dragon, a leg of a man, &c. Pliny speaks of wild Cucumbers and Gourds which were possessed of certain medicinal properties, and gives us a list of eleven remedies for which they were applied. The leaves of the Pumpkin steeped in wine were considered good for the bites of dogs and insects, called *Sep* by the Greeks, perhaps one of the centipede tribe. The seeds were used as a charm to cure the ague. According to L'Obel, the Pompion or Pumpkin was introduced into this country from the Levant in 1370, and till about 1815 this was the principal plant of the Gourd kind cultivated in the British gardens. Parkinson mentions in his "Paradisi" (1629), that in his time only one kind of Pompion was cultivated, but that it would be a waste of time to recite all the forms and colours in which Nature listeth to show herself in this plant. In using it as a culinary vegetable, he tells us that it was customary to take out the inner watery substance with the seeds and fill up the place with Pippins, and, having laid on the cover which was cut off from the top to take out the pulp, bake them together; and the poor of the city as well as the country people do eat thereof as a dainty dish. Gerard, in his "Herbal" (1636), says there be divers sorts of Gourds—some wild, others tame for the garden; some bearing fruit like unto a bottle, others longer and bigger at the end, keeping no certain form or fashion. He tells us that the juice of the Gourd being popped into the ear with oil of

Roses is good for the pain thereof, proceeding from a hot cause. According to Miller, Pompions were the Melons of our early horticulturalists, which word was corrupted into millions, a name by which they are still known in some parts of England by the uneducated classes. It was usual in Miller's time, as in the present day, for the English cottagers to plant Pumpkins on their manure-heaps in the fields and gardens, letting the shoots trail along the Grass without taking much trouble or care of them. In the second volume of the "Transactions of the Royal Horticultural Society," there is a description, with an account of the cultivation and figure of the Gourd called Vegetable Marrow, read in December, 1816, by Mr. Sabine. It had not then been long known in this country. The most probable account of its introduction is that the first seeds were brought here in one of our East Indian ships, and came most likely from Persia, where it is known and called *Cierader*. Phillips states that the Vegetable Marrow was not seen for sale in our shops or markets before 1819. It is now, as we all know, extensively grown, and the fruit is used for culinary purposes in every stage of growth. This plant is considered as a variety of the Pumpkin. Where the climate is warm enough for them, all the varieties of Gourd are cultivated, and form important articles of food; the superabundant shoots are also used for feeding cattle. In America and the islands of the West Indies they are extensively cultivated, and some species grow to a great size. The Rev. Mr. Griffiths, in his "Natural History of Barbadoes" (1750), mentions some which, when cleared of their pith, are capable of containing 22 gallons; but he adds, however, such are very uncommon. Phillips relates that in some parts of America the jugglers or quacks extract the pulp out of the Pumpkins, and fill them with stones, with which they make a great noise and pretend to frighten away all complaints from their superstitious patients.

The Squash (*C. Mellopepo*) is another kind of Gourd, which is a great favourite with the Americans. Gourds of large size were found growing by Captain Cook in the Sandwich Islands. The inhabitants applied them to all manner of domestic purposes; and in order to fit them better for their respective uses, they had the ingenuity to give them different forms by tying bandages round them during their growth; they also had a method of scorching them with a heated instrument, so as to give them the appearance of being painted in a variety of neat and elegant forms. Specimens of these Gourds are to be seen in most museums and collections of natural history in this and other countries. The Gourd and its varieties may have sprung from one original species, and like other plants, have been greatly improved by cultivation. De Candolle, in discussing the history and origin of cultivated plants, refers all the Squashes and Pumpkins to the Old World, but not to India, because they have no name for them in Sanscrit. Some American botanists believe that the Pumpkin and its varieties are indigenous to that continent, as the Indians declare Gourds had been a common food among them long before the Europeans discovered that country; and Champlain, who, in 1604, made a voyage along the coast of what is now the State of Maine, found the inhabitants cultivating *Citrouilles* (Gourds) along with Maize. Pickering, in his "Races of Men," says that specimens of a small variety of Gourd were exhumed from an ancient cemetery in Peru, like those which are still seen in the markets of Lima. M. Naudin, an indefatigable and distinguished botanist, has, during many years, observed and experimented upon all the known forms of Gourds, collected from all parts of the globe, and cultivated at the *Jardin des Plantes*. He reduces them to six species, only three of which, with their numerous varieties, are used as esculents, viz., *Cucurbita maxima*, the large yellow Gourd; *C. Pepo*, the Pumpkin, which he considers as probably the most variable plant in the world; and *C. moschata*, the Water Melon. An interesting paper on this subject will be found in the "American Journal of Science and Art," 2nd ser., vol. xxiv., and also in Darwin's "Variation of Animals and Plants under Domestication." The only plant among our English wild flowers that belongs to the Gourd tribe is Bryony (*Bryonia dioica*), which may be seen climbing over our hedges and thickets in the summer, with its whitish flowers with green veins, and red berries in the autumn. This plant abounds with a fetid and acrid juice.—"Science Gossip."

An Electrical Plant.—According to a Belgian horticultural serial, an electrical plant has been discovered in Nicaragua. In attempting to gather a branch a shock is felt by the hand, as from an electrical machine. The plant is said to affect the compass. It is a species of *Phytolacca*, named *P. electrica*.

Children Poisoned by Eating Laburnum Seeds.—Two little lads living near Malton had a narrow escape from death the other day through eating the seeds of Laburnum. They had been out playing, and had picked the Laburnum pods, thinking they were Peas. One of them became dangerously ill, and the services of a medical man had to be procured. He administered a strong emetic, and adopted other remedial measures, fortunately with success, as the boy ultimately recovered sufficiently to be considered out of danger.

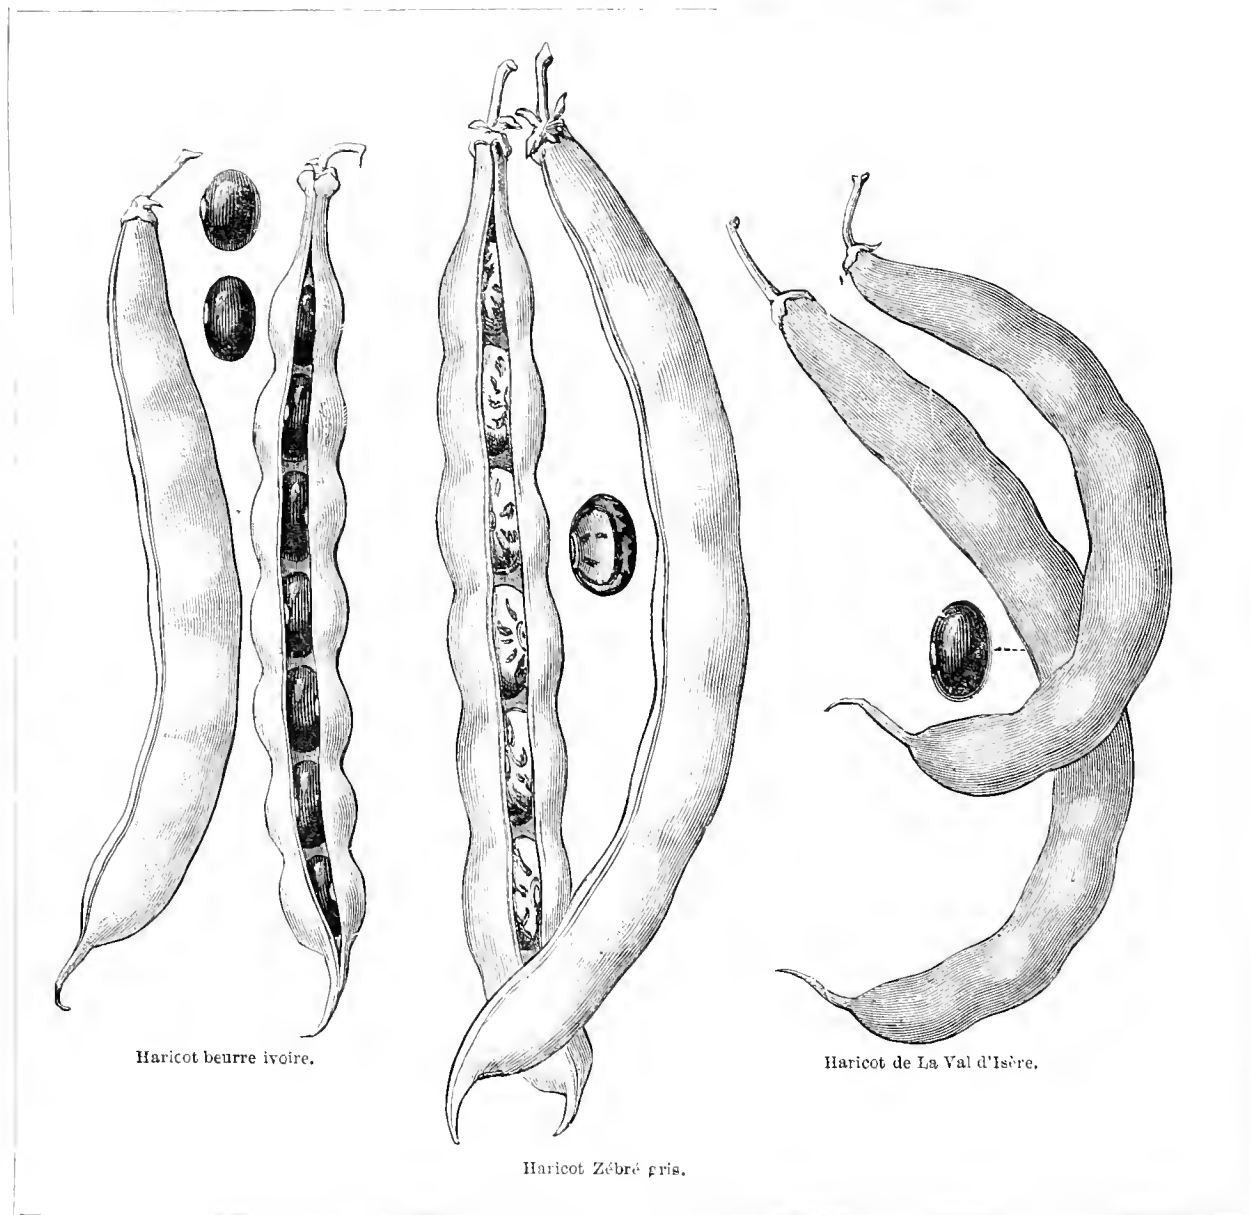

THE KITCHEN GARDEN.

NEW HARICOT BEANS.

Messrs. VILMORIN, ANDRIEU, & Co., of Paris, figure some new varieties of Haricot Beans in their catalogue, which seem to be worthy of introduction. Among them is the Haricot beurre ivoire, distinguished by ivory-white pods, excellent as a vegetable; the Haricot Zébré gris, which is described as a remarkably vigorous variety, thriving in any soil, and affording quan-

BRICK EDGINGS BEST IN KITCHEN GARDENS.

OUR principal walk through the kitchen garden here is edged with common white brick. Mr. Baines has advocated the use of bricks for this purpose in your columns several times, but still it does not appear to be sufficiently known what a neat edging they make for kitchen garden walks. They have been employed here in that way for a number of years, and since I have had charge of the garden I have re-made and drained the walks and re-laid the edges. I have used ornamental edging bricks for the same purpose, but I must say that I like plain bricks better, and if well and carefully laid they

tities of delicious pods, which are tender and good at any age; the Haricot de la Val d'Isère, named after the place in which it is much cultivated, is also strongly recommended. These varieties are described in the supplement to the catalogues of the Messrs. Vilmorin.

will not get out of line for a number of years. I lay them on their sides at an angle of 55°. Mr. Baines, I noticed in one place, recommended the end to be put in the ground; but if used in that way, just double the quantity of bricks would be needed. The Stevens brick, figured in THE GARDEN some time back, I saw in use several years ago at Holkam. It makes a neat edging, but the plain brick costs less and is equally effective. My objection to Box edgings (though nothing looks better when well kept) is that to keep them in order they must be clipped at the busiest time of the whole year (that is, where flower gardening is carried out extensively), viz., the last week in May or first week in June. Box, too, prevents the use of salt for keeping down weeds, a plan which I find much tho

Henderson's Pine-apple Beet.—This is in every respect an excellent variety; but the very best Beet may be spoiled if boiled, for if injured in any way in lifting or in cleaning, the colour boils out of it. The best plan is to cook it in a slow oven.—J. GROOM, *Henham*.

cheapest and quickest for keeping walks clean, if applied at the proper time, and not too much of it used at any one application. Where our walks were not wide enough for a horse and cart to pass along them, I have made them so, an operation which saves an immense amount of wheelbarrow work and economises both time and labour. In some large gardens the manure has to be wheeled all over the garden from the outside, the doors and walks being too narrow to admit a horse and cart. Our walks being well drained and always dry withstand carting with impunity. On the side of our principal walk is a line of cordon Apples planted five years ago, and which have done well. The crops have not been heavy at present, but the fruit individually has been very fine, especially Nelson's Glory, a pale yellow Apple, excellent for kitchen use, and a free bearer. On the other side of the walk is a fine row of pyramidal Pears planted alternately with standard Roses. Many of the later Pears, with the exception of Josephine de Malines and Winter Nelis, after being tried several seasons, were found not to ripen here; we therefore lopped off all the side branches and grafted them from top to bottom with earlier sorts, which bid fair to do well. The sorts put on are Suffolk Thorn, Comte de Lamy, Beurré Superfin, Doyenné du Comice, Beurré Bose, Forelle, Beurré Hardy, and Williams' Bon Chrétien.

Ganton Park, Norwich.

WM. ALLAN.

Winter Salads.—We have this year grown the Witloof for salad purposes; also Endive, but neither of them is eaten generally in consequence of their bitter taste. Some will say, blanch them and then they will be relished; but this has been done with the same results. Nothing is so much appreciated as Lettuces, of which we have an abundance of the Brown-seeded Hardy Cos. I have in one of my cool houses some hundreds packed so closely together that they blanch one another. We use Chives, a little Tarragon, Radishes, Mustard, Cress, and Chervil, and, to please the eye, a few blooms of Tropæolum are put on the top of the bowl.—R. GILBERT, *Burghley*.

Potatoes and Cocoa-nut Fibre.—Cocoa-nut fibre would doubtless prove a good addition to heavy soils intended for Potato culture just as it proves most useful in the cultivation of Pansies and similar plants. Its value consists in its fibrous nature, especially in the case of clayey loams destitute of that character. A frequent use of the quantity mentioned by "G. S. M." (see p. 40) would eventually do much to correct the close, binding nature of heavy soils. Recently much stress has been laid upon spent Hops as presenting a valuable Potato manure, but, on the other hand, it has been shown that Hops are comparatively valueless as a manure; and when it is remembered that they have been subjected to such a scalding that nothing but the mere cuticle of the bracts is left, it is scarcely reasonable to look for much that is nutritious in spent Hops. Cocoa-nut fibre, on the contrary, is the raw material; and, although tough and somewhat inconvertible at first, it eventually gets absorbed by the soil, and thus becomes a useful manure. Its capacity to supply fibre, however, is its chief recommendation, and in assisting to keep stiff soils open and porous it does useful work.—D.

—"G. S. M." (p. 10) asks if it would be a good plan to cover Potato sets with Cocoa-nut fibre. With my experience of Cocoa-nut fibre I should say it would be a very bad plan, unless the fibre was completely rotted. Fresh fibre should only be used as a mulching, for which it is most valuable; if buried in ordinary garden soil it is apt to produce a white, dry fungus, which I believe to be most injurious to plants.—H. N. ELLACOMBE, *Bitton Vicarage*.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Veitch's Autumn Giant Cauliflower.—I have lately been cutting heads of this Cauliflower measuring 9 in. across, quite compact, and as white as snow. I had a quantity of it planted rather late in June, but having had the advantage of irrigating the plants during the warm, dry months of July and August, they grew to a large size. As soon as there was danger from severe frosts, the plants went were raised and laid in close together, later being placed so as to cover them when wanted, but up till this date the weather has been so mild and wet that the covering has been but little used.—WILLIAM TILLEY, *Wetlock*.

Celery as a "Nerve Tonic."—"The cultivation of Celery is now strongly recommended, not only as a source of profit but as a benefit to the community, inasmuch as the habitual daily use of this vegetable is more beneficial to man as a nerve tonic than most persons are aware of. Those especially who are engaged in labour weakening to the nerves should use Celery daily during its season." [Paragraphs like the above have been going the round of the press for many weeks past, though there is probably no evidence that Celery is more valuable in the above respect than other vegetables.]

Market Carrots and Parsnips.—Hundreds of tons of Carrots and Parsnips come to Covent Garden market every week during the winter. The average cost of preparing these crops for market is about 8s. per twenty dozen bunches, viz.:—Digging up roots, 2s. 6d.; washing same, 1s. 8d.; bunching, 3s. 4d.; cost of Willows for tying, 6d.; and to this are to be added carriage and commission.—B.

THE LIBRARY.

DOWNING'S FRUITS AND FRUIT TREES OF AMERICA.*

THERE is probably nothing in the history of fruits more interesting than the magnificent series of hardy kinds raised in America within recent times, and now grown therein. The fact that a single State of the American Union contains more ground devoted to orchards than the whole of the United Kingdom, is good evidence of the enormous development of fruit culture in America, though perhaps it hardly comes home to us so forcibly as the large supplies of good and well-packed American Apples now in all our markets. The two large and well-filled volumes comprising this book also show to what unexampled importance fruit culture has already arrived in "Greater Britain." It is the work of the veteran Downing, the leading American pomologist. It is a noble book, and contains a mass of precious information about all the known fruits cultivated in the United States, and therefore is of great value to the horticulturist. In addition to the descriptions of the numerous fruits cultivated, their synonyms, indexes, and supplements, bringing the work down to recent times, there are many excellent chapters on all that concerns the culture, management, insect enemies, &c., of each fruit. We subjoin a chapter on—

Transplanting.

As nearly all fruit trees are raised first in nurseries, and then removed to their final position in the orchard or fruit garden, as upon the manner of this removal depends not only their slow or rapid growth, their feebleness or vigour afterwards, and in many cases even their life, it is evident that it is in the highest degree important to understand and practise well this transplanting. The season best adapted for transplanting fruit trees is a matter open to much difference of opinion among horticulturists—a difference founded mainly on experience, but without taking into account variation of climate and soil, two very important circumstances in all operations of this kind. All physiologists, however, agree that the best season for transplanting deciduous trees is in autumn, directly after the fall of the leaf; the tree is then in a completely dormant state. Transplanted at this early season, whatever wounds may have been made in the roots commence healing at once, as a deposit directly takes place of granulous matter from the wound, and when the spring arrives, the tree is already somewhat established, and ready to commence its growth. Early autumn planting is for this reason greatly to be preferred in all mild climates and dry soils, and even for very hardy trees, as the Apple, in colder latitudes; as the fixed position in the ground, which trees planted then get by the autumnal and early spring rains, gives them an advantage at the next season of growth over newly-moved trees. On the other hand, in northern portions of the Union, where the winters commence early and are severe, spring planting is greatly preferred. There autumn and winter are not mild enough to allow this gradual process of healing and establishing the roots to go on; for when the ground is frozen to the depth of the roots of a tree, all that slow growth and connection of nutriment by the roots is necessarily at an end. And the more tender sorts of fruit trees, the Peach and Apricot, which are less hardy when newly planted than when their roots are entire and well fixed in the soil, are liable to injury in their branches by the cold. The proper time, in such a climate, is as early as the ground is in a fit condition in the spring. Early in autumn and in spring, before the buds expand, may, as a general rule, be considered the best seasons for transplanting. It is true that there are instances of excellent success in planting at all seasons, except midsummer; and there are many who, from having been once or twice successful in transplanting when trees were nearly in leaf, avow that to be the best season, not taking into account that their success was probably entirely owing to a fortunately damp state of the atmosphere at the time, and abundant rains after the experiment was performed. In the Middle States we are frequently liable to a dry period in early summer, directly following the season of removal, and if transplanting be deferred to a late period in spring, many of the trees will perish from drought before their roots become established in the soil. Spring planting should therefore always be performed as soon as possible, that the roots may have the great benefit of the early and abundant rains of that season, and get well started before the heat of summer commences. For the neighbourhood of New York, therefore, the best periods are from the fall of the leaf to the middle of November in autumn, and from the

* "Fruits and Fruit Trees of America." By C. Downing. New York: J. Wiley & Sons, 15, Astor Place. Two Vols.

close of winter to the middle of April in spring; though commonly the seasons of removal are frequently extended a month beyond these limits. Taking up the trees is an important part of the operation. A transplanter should never forget that it is by the delicate and tender points or extremities of the roots that trees take up their food, and that the chance of complete success is lessened by every one of these points that is bruised or destroyed. If we could remove these trees with every fibre entire, as we do a plant in a pot, they would scarcely show any sign of their change of position. In most cases, especially in that of trees taken from nurseries, this is, by the operation of removal, nearly impossible. But although we may not hope to get every root entire, we may, with proper care, preserve by far the larger portion of them, and more particularly the small and delicate fibres. After being taken up, they should be planted directly; or, if this cannot be done, they should be kept from drying by a covering of mats, and, when sent to a distance, by being packed in damp Moss. We should notice an important exception to this in the case of trees packed for shipping across the Atlantic. In this case they should be packed only in dry Moss, the moisture of the sea being sufficient to keep the roots in good condition, while if packed in damp Moss they will be injured by rotting or excessive growth.

Preparing the Places.

Here often lies a fatal stumbling-block. An English gardener, when he is about to plant fruit trees, talks about preparing his borders; an American says he will dig his holes; and we cannot give a more forcible illustration of the ideas of two persons as to the wants of a fruit tree, or a better notion of the comparative provision made to supply these wants than by contrasting the two phrases themselves. The one looks upon a tree as a living being, whose life is to be rendered long, vigorous, and fruitful by a good supply of food, and a soil mellow and easily penetrated by the smallest fibre; the other considers it very much in the light of a truncheon or a post which he thrusts into the smallest possible hole, and supplies with the least portion of manure, trusting to what he seems to believe the inextinguishable powers of Nature to make roots and branches under any circumstances. It is true that the terms differ somewhat from the nature of the culture and the greater preparation necessary in planting fruit trees in England, but this is not by any means sufficient to justify the different modes of performing the same operation there and here. In truth, in this country, where the sun and climate are so favourable—where pruning and training are comparatively so little necessary, the great requisite to success in the ordinary culture of fruit trees is the proper preparation of the soil before a tree is planted. Whether a transplanted tree shall struggle several years to recover, or grow moderately after a short time, or at once to start into a very luxuriant and vigorous growth, depends entirely upon the amount of care and labour the planter is willing to bestow on the soil for his trees. We have seen several instances where, side by side, one man planted his trees in large spaces of deeply-moved and rich soil, and another in small holes in the common mode, which uniformly showed the trees of the first larger after five years than those of the last after twelve. No fruit tree should be planted in a hole of less size than 3 ft. square, and 1½ ft. to 2 ft. deep. To this size and depth the soil should be removed and well pulverized, and it should, if necessary, be properly enriched by the application of well-rotted manure, which must be thoroughly mixed with the whole mass of prepared soil by repeated turnings with the spade. This preparation will answer, but the most skilful cultivators among us make their spaces 4 ft. or 5 ft. in diameter, or three times the size of the roots, and it is incredible how much the luxuriance and vigour of growth, even in a poor soil, is promoted by this. No after-mending of the soil, or top-dressings applied to the surface, can, in a climate of dry summers like ours, equal the effects of this early and deep loosening and enriching the soil. Its effects on the growth and health of the tree are permanent, and the little expense and care necessary in this preparation is a source of early and constant pleasure to the planter. This preparation may be made just before the tree is planted, but in heavy soils it is much better to do it several months previously; and no shallow ploughing can obviate the necessity and advantages of the practice where healthy, vigorous orchards or fruit gardens are desired. The whole art of transplanting after this consists in placing the roots as they were before, or in the most favourable position for growth. Begin by filling the hole with prepared soil, within as many inches of the top as will allow the tree to stand exactly as deep as it previously stood. With the spade, shape the soil for the roots in the form of a little hillock on which to place the roots, and not, as is commonly done in the form of a hollow; the roots will then extend in their natural position, not being forced to turn up at the ends. Next examine the roots and cut off all wounded parts, paring the wound smooth, cutting from the under side. Hold the tree upright

on its little mound in the hole of prepared soil; extend the roots and cover them carefully with the remaining pulverized soil, as much of the success of transplanting depends on bringing the soil in contact with every fibre, so as to leave no hollows to cause the decay of the roots; not only must this be secured by patiently filling in all cavities among the roots, but when the trees are not quite small, it is customary to pour in a pail of water when the roots are nearly all covered with soil. This carries the liquid mould to every hidden part. After the water has settled away, fill up the hole, and avoid the common practice of shaking it up and down by the stem. In windy situations it will be necessary to place a stake by the side of each tree, to hold it upright, until it shall have taken firm root in the soil, but it is not needful in ordinary cases.

Avoid deep planting. More than half the losses in orchard-planting in America arise from this cause, and the equally common one of crowding the earth too tightly about the roots. No tree should be placed deeper than it formerly grew, as its roots are stifled from the want of air, or starved by the poverty of the soil at the depth where they are placed. It is much the better and more natural process, in fact, to plant the tree so that it shall, when the whole is complete, appear just as deep as before, but standing on a little mound 2 in. or 3 in. higher than the level of the ground about. This, when the mound settles, will leave it nearly on the level with the previous surface.

Mulching.

Mulching is an excellent practice with transplanted trees, and more especially for those which are removed late in the spring. Mulching is nothing more than covering the ground about the stems with coarse straw or litter from the barn-yard, which, by preventing evaporation, keeps the soil from becoming dry, and maintains it in that moist and equable condition of temperature most favourable to the growth of young roots. Very many trees, in a dry season, fail at midsummer, after having made a fine start, from the parched and variable condition of the earth about the roots. Watering frequently fails to save such trees, but mulching when they are planted will entirely obviate the necessity of watering in dry seasons, and promote growth under any circumstances. Indeed, watering upon the surface, as commonly performed, is a most injurious practice, as the roots, stimulated at one period of the day by water, are only rendered more susceptible to the action of the hot sun at another, and the surface of the ground becomes so hard by repeated watering, that the beneficial access of the air is almost cut off. If trees be well watered in the holes while transplanting is going on, they will rarely need it again, and we may say never, if well mulched directly after planting. The best manure to be used in preparing the soil for transplanting trees is a compost formed of two-thirds muck or black peat earth, reduced by fermenting it several months in a heap with one-third fresh barn-yard manure. Almost every farm will supply this, and it is more permanent in its effects, and less drying in its nature, than the common manure of the stable. An admirable manure recently applied with great success is charcoal—the small broken bits and refuse of the charcoal pits—mixed intimately with the soil. Air-slaked lime is an excellent manure for fruit trees in soils that are not naturally calcareous. Two or three handfuls may be mixed with the soil when preparing each space for planting, and a top-dressing may be applied with advantage occasionally afterwards to increase their productive-ness. But wherever large orchards or fruit gardens are to be planted, the muck compost heap should be made ready beforehand, as it is the cheapest, most valuable, and durable of all manures for fruit trees. Pruning the heads of transplanted trees at the season of removal we think generally an injurious practice. It is certainly needless and hurtful in the case of small trees, or those of such a size as will allow the roots to be taken up nearly entire; for as the action of the branches and the roots is precisely reciprocal, and as new roots are rapidly formed just in proportion to the healthy action of the leaves, it follows that by needlessly cutting off the branches we lessen the vital action of the whole tree. At the same time, where trees are transplanted of so large a size that some of the roots are lost in removing them, it is necessary to cut back or shorten a few of the branches—as many as will restore the balance of the system—otherwise the perspiration of the leaves may be so great as to exhaust the supply of sap faster than the roots can collect it. A little judgment only is necessary to see at a glance how much of the top must be pruned away before planting the tree to equalize the loss between the branches and the roots.

Preparation for Transplanting.

When it is necessary to transplant fruit trees of large size, the best practice is to prepare them previously by digging a trench round the whole mass of roots, undermining them, and cutting off all roots projecting beyond this line. The trench should be dug at such a distance

from the tree as will include all the large and sufficient ball of roots, and it should be done early in the spring when it is desirable to remove the tree the next year. After all the roots that extend to this circular trench are cut off, the earth is replaced, and by the season following an abundance of small fibres is sent out by the amputated roots, which, when the whole is removed, will insure the success and speedy growth of the tree. This is more completely the case when the tree is prepared two years before transplanting. A variation of this mode, which has been found quite as successful and less laborious, consists in leaving the trench open and covering it with boards only, or boards with a top layer of turf. The tree then is somewhat checked in its growth, it throws out an abundance of small fibres into the ball of earth containing the roots, and is the next season transplanted with great ease and safety. The proper size for transplanting varies somewhat with the sort of tree and the kind of culture intended. It is, however, a maxim equally well settled both among theorists and the best practical men that health, immediate vigour, and duration are all greatly promoted by transplanting fruit trees of small size—from 3 to 7 ft. We are fully aware with what impatience the tyro or a person who knows little of the culture of trees looks upon trees of this size—one who is eager to plant an orchard and stock a garden with large trees thinking to gather a crop the next year. The latter may indeed be done, but the transplanting so affects the tree that its first scanty crop is followed by a long season of rest and feeble growth, while the plantation of young trees is making wood rapidly, and soon comes into a healthy and long-continued state of productiveness, often long indeed before the large trees have fairly arrived at that condition. The small tree, transplanted with its system of roots and branches entire, suffers little or no check; the older and larger tree, losing part of its roots, requires several years to resume its former vigour. The constitution of the small tree is healthy and unimpaired; that of the large is frequently much enfeebled. A stout and vigorous habit—what the nurserymen call a good stocky plant—is the true criterion of merit in selecting fruit trees for transplanting.

Selecting the Trees, Heeling-in, and Thawing when Frozen.

Trees intended for orchards, being often more exposed than those in gardens, should be somewhat larger—not less than 6 ft. or more than 8 ft. is the best size. For gardens, all experienced cultivators agree that a smaller size is preferable; we prefer plants two years old from the graft. Most gardeners abroad, when they select trees with more than usual care, take what are called maiden plants—those one year old from the graft—and there can be no doubt that, taking into account health, duration, and the ease with which such a tree can be made to grow into any form, this is truly the preferable size for removal into a fruit garden. But we are an impatient people, and it is not till after another century of trial and experience in the culture of fruit trees that cultivators generally in this country will become aware of the truth of this fact. The facility with which the different fruit trees may be transplanted differs considerably. Plums are generally removed with most success, and after them nearly in the order as follows:—Quinces, Apples, Pears, Peaches, Nectarines, Apricots, and Cherries; the latter succeeding with some difficulty when of large size.

Laying in by the heels is a practice adopted as a temporary kind of planting when a larger quantity of trees is at hand than can be set out immediately. A trench is opened and the roots are laid in and covered with soil, the tops being previously placed in a sloping position, inclining to within a few feet of the surface. In this way they are kept fresh and in good order until it is convenient to plant them finally. In northern districts, where the autumn is often too severe for planting, and the spring is frequently too late to receive trees in time from nurseries farther south, it is a common and successful mode to procure trees in autumn and lay them in by the heels until spring, covering over the tops of the more tender sorts, if necessary, with coarse litter. We have often known trees entirely destroyed by want of a little extra care in heading them in. Select first a dry knoll, or position where no water can stand, and, if possible, sheltered from the southern sun. After first digging a trench 1 ft. or more deep, lay the trees down at an angle of about 45°, their tops to the south; then make the soil mellow and fine, and thoroughly intermingle it with the roots, filling all interstices, and covering them at least 18 in. deep.

Trees are sometimes received in a frozen condition. They should then be placed at once, without unpacking, in a dark cellar and left until gradually thawed out, or they may be at once, if the earth will allow, buried, tops and roots entire, beneath the ground, and there left for a few days, or until a moist, cloudy day occurs for opening and exposing them to the light and air. This latter course is also a good one for trees that are received in a dry or

shrivelled state. In planting an orchard always avoid placing the trees in the same spot, or near, where an old tree stood before. Experience has taught us that the growth of a young tree in such a position is weak and feeble, the nourishment suitable to that kind of tree having already been exhausted by a previous growth, and the soil being half filled with old and decayed roots, which are detrimental to the health of the young tree.

HANDY GARDEN TOOLS.

By means of a little ingenuity as regards the construction of garden tools much labour may often be saved. Fig. 1 shows a contrivance which will be found useful in the transplantation of vegetables. It consists of two pieces of wood 1 in. thick, and of the same size; to one of them is fastened a pair of handles, and in the other a number of holes is bored 3 in. apart, which are supplied with movable pegs, in order that holes may be made in the ground at 3 in., 6 in., or 9 in.

Fig. 1.

asunder, as may be required. When the pegs are in their proper positions, the piece with the handles is placed on the top, and secured by means of small iron bolts, on which nuts are screwed (1). When a border is required to be planted, say with Cabbage plants, one person must go on each side of the border, and if the ground be in workable condition, they will be able in a few minutes to pierce the ground with rows of holes at equal distances apart; the distances between the rows may be easily regulated by means of the movable peg (4), which is shorter than the rest, being placed in the horizontal slip (3), which is filled with holes also at the required distances asunder. This implement may, of course, be made of any size. Fig. 2 represents a small iron tool for rapidly making holes for

Fig. 2.

Fig. 3.

large seeds, such as Peas and Beans, at equal distances apart, and of the same depth, conditions on which they usually prove more satisfactory than when sown in the ordinary way. Fig. 3 represents a tube of galvanised iron, zinc, or tin, by which holes may be made in shallow or poor soils, and filled with good soil, in which to grow Carrots, Parsnips, Beetroot, or other vegetables, either for exhibition or general purposes. If screwed into the ground the soil will, of course, work up the centre of the tube, which, when full, may easily be emptied by being turned upside down. S.

Allotment Gardens for the Poor.—Respecting these Mr. J. Wright writes to the "Times" as follows from Springwell, Saffron Walden:—"In a parish which formed part of the estate of the late Lord Maynard in Essex, his lordship required his tenants to allow

every cottager to occupy from 10 to 40 poles of land near his dwelling, and at the same rent per acre as that paid by the farmers; and many years back, during his lordship's life, I have heard blessings invoked upon him for having thus increased the food of the poor; and as the same system is continued by the trustees of the estate, I should be glad to see the labourers, by the work of their own hands, raise some lasting memorial to the memory of so benevolent a nobleman. In the parish of Willesden, in which I have resided for the last thirty-five years, I established allotment gardens, of which there are now about sixty, and in the summer months any one may see in Pound Lane, in a field granted by Mr. Froust, of Neasden, the working of the system, and the highly-prized productions of the tenants. These allotments tend to encourage industry and skilled labour to such an extent, that every able-bodied man can find employment at considerably increased wages; the Union houses are no longer needed, and ought not to exist, except as asylums for the aged and hospitals for the afflicted."

PLANT FERTILIZATION.

LOBELIA SYPHILITICA.

The way in which plants are fertilized is at present, more than ever before, a subject of general interest, and it is one from which every admirer of flowers, whether a botanist or not, may derive instruction. Many flowers may or do fertilize themselves. Many depend upon the wind to carry the pollen from the male to the female. Others are wholly dependent, it would seem, upon insects for their fertilization, and among this last class we propose to speak of *Lobelias*, selecting *L. syphilitica* for illustration. This is the blue or purple Cardinal Flower that appears to prefer moist, half-shady places, and may be found in the fresh water marshes bordering rivers and streamlets. The petal-like filaments of the stamens, though separate below, are coherent above, and with their anthers form a slender tube, the anthers looking inward. The pistil in the bud is quite short, lengthening as the bud unfolds, until finally the stigma has made its way through this tube for the distance, it may be, of $\frac{1}{4}$ in. or more, much the same as if one should push his finger through the finger of a glove with the end cut off, the end of the finger representing the stigma, the rest of the finger the style, and the shortened glove-finger the tube of the united filaments and anthers. Now, the anthers mature and burst at the same time, or a little before the stigma of the elongating style reaches them, filling the little round cavity (the sides of which are the united anthers, and the bottom of which is the closely-fitting stigma) with pollen. The elevation of the stigma by the continued growth of the style presses upon this pollen, causing it to ooze out at the top of the tube, the same as water would from the top of a syringe if the piston-rod were very gently pressed. If flour could be substituted in the syringe for water, the analogy would be closer. It would appear, therefore, that inasmuch as the pollen of every flower rests upon the stigma for a considerable time (from twelve to forty-eight hours), the ovules are necessarily fertilized by the pollen of the anthers of the same flower. Indeed, if our observations were to cease at this stage, we could arrive at no other conclusion.

After watching the flowers of *Lobelia syphilitica* as long as our patience could be induced to hold out every day for a week or so, and not seeing a single insect upon any one of 100 flowers before us, we should ourselves have concluded that they must be self-fertilizing, were it not for the fact that the stigmas, so far as we could judge, were never ripened or fit for the reception of the pollen until they had passed through and beyond the coherent anthers. In a neighbouring field and along the banks of a stream we happened one day to come upon a plantation of this *Lobelia*, consisting of scores of plants in every stage of bloom, and here we were not obliged to wait long for a full understanding of what we had wasted many hours over in our own garden. Let us now note that the corolla consists of two lips, the posterior (upper) having two erect lobes, the lower recurved and more spreading. As soon as the pollen bursts the cells of the anthers, the pistil begins to recurve toward the lower lip, somewhat as a fish-hook is curved, though less, so that the top of the stamen tube almost rests upon the lower lobes of the corolla. Here a bee or other insect would naturally light in order to procure the honey secretions within. A big humble-bee was the first visitor, and indeed the only one whose behaviour we need record. Forcing his head and thorax beneath the crooked end of the staminate tube or pistil, if the latter had yet sufficiently protruded, and between it and the lower lip of the corolla, the tip of the tube or stigma, as may be, pressing upon the middle of the thorax, would part the hairs to the right and left the same as the hair of one's head is parted with a comb. When the bee selected flowers in that stage in which the pollen was being forced out of the tube, there was always a quantity on the outside cohering to that within. This, of course, would

necessarily be deposited upon the thorax of the bee as he entered the flower, and, from its different colour, marked the "part" so distinctly that it could be seen 6 ft. away. When the bee, withdrawing from this flower, visited another, it was as likely as not to happen that all of the pollen had been forced through and out, and that the pistil, maturing afterward and having made its way through the tube, was ready to receive the pollen which was to creep down the style and to perform its part in the creation of embryos in the ovules of the ovary. This pollen was abundantly supplied to the ripened stigma by the "part" of the thorax of the humble-bee. The stigma, before maturity and while—from the growth of the style—it is slowly making its way through the tube of stamens, is surrounded with a fringe of short hairs. After the stigma has made its way through, it begins to swell and ripen. Two convex lobes are developed, and the fringe of hairs is now covered by these lobes, and may be seen underneath. Had the stigma matured while still within the tube, its increasing size would have split the anther tube, and thus no cross-fertilization could occur, since the stigmas, ripened within the tube, could alone come in contact with pollen of the same flower. The fringe of short hairs, it may be supposed, acts to rid the anthers of every grain of pollen, for, though we divided lengthwise in two perhaps twenty tubes after the stigmas had passed through them, not a grain of pollen was visible. In several instances the stigma was caught or held in the anther tube. The style, continuing to grow, thrust itself between and outside of the filaments, where the latter was not united, in the shape of a bow. One of these which we marked did not perfect seeds, which, so far as it goes, is evidence either that the stigma did not mature when thus confined, or that the pollen is not potent upon the stigma of the same flower.—"Rural New Yorker."

Moss on Fruit Trees.—Will you kindly inform me how I can get rid of Moss on my fruit trees?—J. [Many scrape it off with a piece of hoop-iron, but neither scraping, washing, painting, nor any other method except such as would be injurious to the trees, have any permanent value. The existence of Moss on fruit trees is caused by the stagnation of water round the roots, too deep planting, poverty of the soil, &c.; this is removable in the case of young trees, whose growth may be improved under more liberal treatment; but generally irremovable in old ones, on which the Moss does little harm beyond, perhaps, that of harbouring insects. In some cases, however, a great improvement may be made by carefully removing the surface soil down to the roots, and replacing it with richer materials, covering the roots just enough to prevent their being injured.—S.]

Keeping Potatoes for Two Years.—This is no novelty. For several years it has been done by Mr. Robert Fenn by simply keeping them in paper bags in a dry, cool place, and looking them over occasionally to prevent any of the shoots from pushing. With many kinds, the eyes of which are few, it is not often that more than one or two shoots push at once, and therefore if these be kept in check little exhaustion is experienced. In the case of sorts covered with eyes that all start at once, the exhaustion is rapid, and it is impossible long to keep growth in check. A close observation of the habits of Potato tubers in the spring reveals the fact that they are capable of accomplishing but little growth unassisted. Given a dry shelf and plenty of light and air, and it will be found that the shoots pushed by the tuber seldom exceed from 1 in. to 2 in. in length, and at that point they will remain until the tuber finally decays. It is only when the young rootlets come into contact with moisture or soil that farther growth is the result. The blanched growth obtained in a dark, confined place, affords no guide to the matter, as there the conditions are unnatural. This fact shows plainly that the after growth of the Potato depends much less upon the strength or size of the tuber than is usually believed. Given a healthy shoot, even from a small tuber, the rest must depend upon the quality of the soil.—A. D.

Midland County Fruits.—Will you kindly favour me with the names of a few of the best kinds of fruits for planting in cottage gardens in the Midland Counties?—A. B. [The following are all useful kinds which invariably bear good crops about Nottingham and Derby, viz.:—*Kitchen Apples*—Lord Suffield, Blenheim Orange, Northern Greening, Normanton Wonder, Hawthornden, and Keswick Codlin. *Dessert Apples*—Court-pendu Plat, Pike's Pearmain, Pearson's Plate, New Besspool, Lemon Pippin, and Cackle Pippin. *Pears*—Beurré de Capiaumont, Beurré Diel, Marie Louise, Winter Nelis, Easter Beurré, and Glou Morcean. *Plums*—Orleans, Victoria, Goliath, Jefferson, Green Gage, and Violet Hative. *Gooseberries*—Warrington, Crow Bob, Green Gage, Champagne, Woodward's Whitesmith, and Smooth Yellow. *Currants*—Black Naples, White Dutch, and Red Grape. *Strauberies*—Keen's Seedling, Sir C. Napier, Eclipse, President, Elton Pine, and Wilmot's Superb.—S.]

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

JANUARY 17.

THIS meeting was an attractive one, the groups of Orchids and other decorative plants exhibited being of a superior character. New fruits were represented by a Pine-apple from Mr. Miles, which will be more fully described hereafter, and as this particular variety possesses the merit of being a good keeper, we hope Mr. Miles will give us particulars as to its general character and usefulness. A cluster of Grapes sent by Mr. Fowler, of Harewood, under the name of Charlesworth Tokay, was in excellent condition, and interesting as being cut from the original Vine of that name at Harewood, which during the past season has ripened 300 bunches. Some Mushrooms shown by Mr. Hepper were perfect examples of good culture. New plants shown on this occasion were limited to Orchids, and consisted of *Schlimmia trifida*, *Lælia Dayana*, and the singular *Dendrobium Lindleyanum*. These all came from Sir Trevor Lawrence's collection; Mr. B. S. Williams had, however, a blooming plant of the *Lælia Dayana*, which is a richly coloured addition to the genus. Messrs. Charles Lee & Son sent a large group of hardy variegated and other evergreen shrubs.

First-class Certificates.—These were awarded to the following new and rare plants:—

Lælia Dayana (Spysers).—This is a charming addition to dwarf winter-blooming *Lælias*. Its pseudo-bulbs are slender, fusiform, from 2 in. to 3 in. in length, each bearing an oblong leaf, as long or longer than the membranous-sheathed bulb. Flowers solitary, at first sight, reminding one of those of a richly coloured variety of *L. præstans*. They are of a bright carmine colour, the involute base of the lip being pure lilac in colour, and the tip of the lip a rich purple. There are five principal and four secondary purple plates on the lip, and these as seen up the white throat are very beautiful. It is a plant, well worth culture.

Pine-apple Lord Carington (Miles).—A small but symmetrical fruit, having a white exudation on brownish-orange pips. The fruit shown, which was delicious in flavour, had been cut from the plant seven weeks ago, so that, apart from the high flavour, its keeping qualities are sure to render it worthy of special attention.

A second-class certificate was awarded to *Dendrobium Lindleyanum* (Spysers). This has the habit of a broad-bulbed specimen of *D. nodatum*, with flowers similar to those of a pale variety of *D. crassinode* or *D. tortile*. It has the singular habit of bearing its flowers at the slender apices of its knotted bulb.

A botanical commendation was awarded to *Schlimmia trifida*, a singular Orchid which came from Sir Trevor Lawrence's collection. This is in habit like a *Gongora* or slender-bulbed *Stanhopea*, and bears a five-flowered spike 9 in. or 10 in. in length and naturally pendulous. The white flowers are of a wax-like consistence, glisten like ivory, the only colour being on the curious knobbed, dagger-like lip, which is spotted with orange, the interior of the pouch having a few lilac dots. The two narrow-curved petals and the upper sepal are distinct, but the lateral sepals are fused together, the result being an elegant ewer-shaped *Cypripedium*-like pouch. It is one of the most deliciously fragrant of all Orchids, and well deserves culture.

Miscellaneous Plants.—From Messrs. Veitch & Sons came an attractive group of rare Orchids and Palms of various kinds, together with a richly coloured collection of various Persian Cyclamens, some Hybrid *Amaryllises*, and some remarkably well-grown *Lily of the Valley* in pots. Among the Orchids we noted several distinct varieties of *Odontoglossum Alexandrae*, *O. Andersonianum*, bearing two good spikes of creamy-yellow brown-spotted flowers; the pure white variety of *O. Roezli*, and the curious little *O. crocidictum*. A plant of *Cologyne cristata* bore several spikes of ivory-white flowers amongst graceful, glossy foliage. A pot of the pretty lilac-tinted *Pleione humilis* was furnished with nine or ten remarkably fine flowers, and several *Cypripediums*, *Lycastes*, and *Cattleyas* of the *C. Trianae* section made up a charming group, to which a Davis medal was recommended to be awarded as much for excellent culture as for floriferous beauty of colour. In this collection was moreover the bright scarlet *Aphelandra aurantiaca* (Roezli), which well deserves culture as one of the most brilliant of stove plants. Messrs. Charles Lee & Son, of the Royal Vineyard Nursery, Hammersmith, contributed a mixed group of stove and greenhouse plants, among which were Palms, *Dracænas*, Ferns, *Crotons*, and dark-leaved *Cycads*; also a well-grown group of new and rare hardy Conifers, *Euonymuses*, *Hollies*, &c. Associated with these was also a small specimen of the Japanese Umbrella Pine (*Sciadopitys verticillata*). Mr. B. S. Williams, of Holloway, furnished a large bank of Orchids, Ferns, Palms, scarlet-berried *Solanums*, and other decorative plants, all in excellent condition, the Orchids especially being much enhanced by being tastefully arranged over an undergrowth of *Adiantum Farleyense*. Among them we noted *Saccolabium giganteum*, bearing two good spikes of flowers, *Cypripedium Davi*, producing two fine flowers, the fragrant *Cymbidium ensifolium*, *Oncidium Weltoni*, various *Lycastes*, *Odontoglossos*, and others. Mr. Ollerhead, gardener to Sir H. Peck, Wimbledon House, showed a small group of well-grown *Crotons*, *Dracænas*, *Aralias*, and a very fine specimen of the graceful and but little-known *Lycopodium Phlegmaria*; also a good plant of the rich green plumose *Todea superba*. Mr. R. Dean exhibited Lee's new Violet *Victoria regina* in good condition, also mauve Neapolitan Violets, and one or two early Primroses. From the Society's garden at Chiswick came cut specimens of hardy

winter-flowering shrubs, among which were *Lonicera fragrantissima*, a smooth-leaved evergreen shrub, bearing white fragrant flowers, and *L. Standishi*, a kind with similar flowers, but a more abundant bloomer; the shoots of this last-named sort were nearly destitute of foliage, which is rough, and slightly different in shape from that of *L. fragrantissima*. These plants are doubtless varieties of the same species, judging by the flowers, but the one is evergreen, and the other for all practical purposes deciduous. Cut sprays of *Chimonanthus grandiflorus*, loaded with sweet-scented blossoms, also came from the Society's garden.

Fruit.—Mr. Miles, gardener to Lord Carington, Wycombe Abbey, showed new Black Hamburg Grapes in good condition, and Mr. Fowler, of Harewood, exhibited a cluster of the true Muscat of Alexandria under its synonymous name of Charlesworth Tokay. Mr. J. Perkins, Thornham Hall, Suffolk, sent a small fruit of Cox's Golden Gem Melon, and a seedling kitchen Apple named Hart's Glory came from Messrs. Lott and Hart, Whitehill Nursery, Faversham. Mr. J. Hepper, The Elms, Acton, showed three boxes of Mushrooms in excellent condition, and a dish of *Josephine de Malines* came from the Society's garden at Chiswick, where it proves to be one of the latest of all Pears, and as such well deserving of notice.

OBITUARY.

WE have to record with regret the death of Mr. ALFRED SMEE, F.R.S., an event which occurred at his residence, Finsbury Circus, on Thursday, the 11th inst., at the age of fifty-eight. Mr. Smeed held the office of Surgeon to the Bank of England for many years. He took great interest in gardening, and one of his latest works was "My Garden," in which he minutely describes his garden at Carshalton. He was for many years a member of the Scientific and Fruit Committees and of the Council of the Royal Horticultural Society, and was a zealous promoter of town gardening.

NOTES AND QUESTIONS—VARIOUS.

A Winter-flowering Honeysuckle (*Lonicera fragrantissima*).—Perhaps Mr. Ingram, Belvoir, will kindly say whether his fine plants of this Honeysuckle on the terrace wall of the castle are in flower thus early or not this exceptionally mild winter; if so, this would add an additional recommendation to the Rev. Mr. Ewbank's testimony to its usefulness at this early season in the Isle of Wight. It is one of the sweetest and most useful for cutting of all the Honeysuckles.—D. T. F.

Plants in Bloom Out-of-doors in Dorset.—The following is a list of the flowers which I gathered out-of-doors on the 12th inst., viz., *Andromeda dorabunda*, *Berberis Darwini* and *Aquifolium*, *Gastonbury Thorn*, *Chimonanthus fragrans*, *Cydonia japonica*, three varieties of *Heath*, *Christmas Rose*, *Iberis sempervirens*, *Jasminum nudiflorum*, *Lonicera flexuosa*, *Laurustinus*, *Viola major*, *Violets* (Neapolitan and Czar), *Veronica speciosa* and *salicifolia*, and *Polyanthuses*, *Daisies*, *Snowdrops*, *Nemophila insignis*, and *Arabis*. A crimson *Rhododendron* is just opening its flowers.—D. UHILL, Moreton, Dorchester.

Pyracantha and Snowberries for Winter Decoration.—I agree with Mr. Williams, of Ormskirk, that the *Pyracantha* should have the second place to the *Holly*, if it should not go before it. No plant yields such a rich profusion of berries as the *Pyracantha*, and the branchlets are so slender that they may often be used for designs or letters *en masse*. This, however, sacrifices the plants, and is not to be recommended, unless where a free growth is allowed on purpose. The *Snowberry* is very striking when perfect, but it is so often marred or tarnished, and does not bear quite so well. *Cotoneasters* are hardly as a rule, sufficiently large or brilliant for indoor decoration.—F.

Violas and Drought.—Mr. Groom's experience on this subject differs from mine. The general impression that *Viola* are not suitable for dry places in dry seasons is quite correct. I have grown *V. cornuta* and others by the thousand, and was obliged to relegate the whole to a few shady nooks and corners in the mixed border. They proved total failures again and again in our back garden. *Viola cornuta alba* I now grow on a shady border for bouquet purposes, and find it most useful; it is pure white, and has a delicate odour of *Violets*.—T. S.

Derbyshire Spar.—I agree with "J. G." (see p. 36) that this is very effective in plant houses, but it is dear. Were agents to deliver it carriage free at leading towns throughout the kingdom, it is probable a large trade might be established in it, but as it is, if any one wants a ton or two of it he is mostly so victimized that the spar is not considered worth what it costs.—D.

Coloured Primroses the Earliest.—Can any one explain how it is that the brighter-coloured varieties of the common Primrose—notably pink or crimson strains—flower earlier than the common type? Has colour any correlation to precocity? In all structural and botanical characteristics they are identical; in fact, it seems pretty certain that the earliest purple Primrose is merely a sport from the common kind, and yet it is mostly a month, six weeks, and sometimes two months earlier. Why?—D. T. FISK.

Preserving Stakes.—Let "W. S." (see p. 34) have his stakes thoroughly dry, and then paint them over with carbolic acid. Another good way of preserving them is to dip their points in pitch, which excludes air, and therefore obviates decay.—CHARLES CHAINOR, *The Hollies, Exham*.

Crocuses Eaten by Rats and Mice.—Catch and kill them is the only sure remedy. Set traps on the scratched places, and their numbers will soon be thinned. The bulbs may also be wetted and rolled in red lead or sprinkled lightly with paraffin oil before being planted. But after all there is no safety except in the death of the rodents.—T.

— In order to kill mice which attacked my *Crocus* borders I set traps baited with cheese, but finding that plan fail I strewn sifted ashes and soot over the bulbs, and since I that not one *Crocus* has been touched.—J. J.

— In reply to "W. T." I would say, plant the *Crocuses* 6 in. deep, and the mice will not scratch them up and eat them. They will bloom somewhat later, but that is better than no *Crocuses*.—J. G. N.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

WILD GARDENING FOR PUBLIC PARKS.

THE idea of the wild garden may be carried out with success and appropriateness in public parks, the extent and variety of the surface of these presenting great advantages. In such places there are generally large surfaces which cannot be decorated in the ordinary way, owing to the expense, even if it were desirable to decorate them in that manner, which it certainly is not. It would, for example, be most unwise to create any set design or to interfere with the perfect freedom of the surface of the ground in many parts of great parks. In wild gardening there is no need to do this. So, too, in public parks it is, or ought to be, desirable to give precedence to the nobler types of vegetation—the trees and wild gardening may be carried out beneath and around them without in the least injuring them. This cannot be said of any other form of garden embellishment. In many parks where the dismal system of digging the surface, and mutilating the roots and branchlets every winter is carried on, the wild garden offers the best way out of the difficulty. One of the best reasons for the adoption of this system in the public gardens in and near our large cities would be to bring near the people—artists, designers, and all concerned—nearly the whole flower-life of the northern and temperate world. In no other way at all can this be effectively done. All systems of mixed borders, &c., sink into miserable primness, prettiness, and artificiality in the face of what may be done by wild gardening; and all other systems compared with it are as expensive as they are unsatisfactory. With wild gardening, all that is required is some knowledge of hardy plants, and judgment in finding the most suitable positions for them. The islands, margins of water, groves, shrubberies, and turf in public parks invite the wild gardener at every turn. Here, where the shrubbery fringes the water, he sees a lovely vision of Irises to come—and proceeds to secure their coming by planting them, and in a way that they may require no further attention; there, an open growth of trees, with Grass not too trim between, invites groups of Daffodils and Snowflakes; this islet may be graced with the spikes of the common blue Lupine; that more distant one with the showy rose-coloured Loosestrife. This steep and somewhat arid bank, on which the Grass is not very fresh, will prove a pleasant home for trailing shrubs, allowed their way on the turf; one grove may be filled with coloured Primroses, if only to contrast with their less showily arranged relatives, which would, of course, also find a place; the blue early Scillas would be at home anywhere on the Grass with the Snowdrops. In this way innumerable beautiful aspects of vegetation might be enjoyed. It may be objected, that in the case of city parks some of these types would not thrive—granting that this is true, it is only a question of selection after all, and the avoidance of smoke-fearing species. The materials at our disposal are so ample that we can never use the half of them, even if obliged to reject kinds that would not thrive in polluted air.

CORDYLINÉ VIVIPARA, OR CHLOROPHYTUM STERNBERGIANUM.

WHAT does your correspondent "R." (see p. 3) mean by "perfectly hardy" with respect to this very interesting plant? I fear that such a statement will lead to disappointment. Its proper place is a room in dwelling-house. It is one of the most accommodating and enduring of plants, bearing all sorts of neglect and hard usage; therefore it is most suitable for a living-room, which is so frequently the death-place in time of even hardy plants. In Germany, Goethe's Plant, as it is commonly called, is very generally grown. From a small shelf at the top of the window it hangs its flexible shoots, weighted with tufts of young plants, down as far as the floor, forming an

excellent blind. I have seen it set around the iron or earthenware stoves, where it endures the vitiated air of the closely-shut rooms, double-windowed and gas-lit. A good way of growing it for the sake of variety is to train the long shoots of a large plant of it up stakes, and then let them hang and grow as they please; so light yet wiry are these shoots, that on opening the door or window they move about with the slightest draught. The young plants dangling at their ends are at once visible, but the slender stalks from which they depend are not seen at the first glance, and the plant both interests and surprises those unacquainted with it. The stove, in which it grows very quickly, is unsuitable for it, inasmuch as mealy bug is liable to congregate among its fleshy air roots, from which it is impossible thoroughly to dislodge it. A large plant of it here hanging from the roof had got so desperately infested, that after picking until worn out, and burning the worst tufts, I determined to try an experiment with it. I had the plant turned out of its basket, its solid mass of roots plunged into a deep bucket of water, and there it remained for more than a fortnight. By that time the bug was thoroughly killed, and the plant had no appearance of life; however, it was laid up on a shelf just as it was, and in the course of two or three weeks small, green shoots made their appearance here and there. I then cut up the lump and potted off the sprouting portions, which made as good plants as those grown in the usual way. F. J. HORE.

Wardie Lodge.

GRAPE-GROWING FOR MARKET.

WHENCE come the large quantities of beautifully coloured Grapes which may at all times be seen in the London fruiterers' shops is a question easily answered after paying a visit to some of the suburban fruit-growing establishments—that of Mr. Sweet, at Leyton, for example. Here are five or six span-roofed houses, each from 130 ft. to 140 ft. in length and 35 ft. in width, almost entirely devoted to Grape culture. As in most other places of the kind, the glass structures here are not of a pretentious character; on the contrary, they are plain, light, airy houses, sufficiently lofty to permit the necessary operations inside being conveniently carried on, yet not so high as to necessitate a useless waste of artificial heat; they are efficiently ventilated and well supplied with hot-water pipes, which are distributed in an equal manner about the house, thus obviating the necessity of making them intensely hot even during the coldest weather, and thus avoiding the evil results often experienced in Grape-growing from the attacks of red spider or thrips. The borders in which the Vines are planted are principally inside, the reason for this being that outside borders take up too much valuable space; and moreover in the case of early houses they require to be warmed by means of fermenting material of some kind, which cannot well be either obtained or afforded in such places. The rod and spur system of training is the one adopted here, and the chief aim is to get the wood thoroughly ripened previous to pruning: this end attained, success is almost a certainty. In pruning, the shoots are not cut closely into the old wood, as is often done in private establishments, but a good plump bud, which is likely to produce a good bunch of fruit, is left on each spur. Some of the Vines have two, three, or four rods each, others only one. In some cases Vines are planted on each side of the house, each row furnishing one half, but in others only one side is planted and the rods trained so as to cover the whole of the roof. This latter plan is a very good one, as it admits of fresh Vines being planted on the vacant side whenever it becomes necessary, without in any way disturbing the roots of existing ones; besides, the newly-planted Vines can be allowed to get well established before the older ones are discarded, and thus neither Vines nor crops are sacrificed. The chief kinds grown here are Black Hamburgh, Muscat of Alexandria, Black Alicante, Lady Downes, and a few canes of Gros Colman. A house filled with the two former kinds is just now breaking strongly into leaf, and will furnish ripe fruit late in May or early in June. Fruit of Alicante is still hanging in good condition, a piece of paper being fastened over the top of each bunch to preserve it from damp and dust. These Grapes now realize from 6s. to 7s. per

lb. Watering is an operation to which due attention is paid. Each house is watered four times during the season, and at each watering sufficient is given to thoroughly saturate the whole of the soil down to the drainage. The first watering is usually given immediately the Vines are pruned, the next when the leaves are expanded, a third when the fruit is fairly set, and the last when stoning has been completed. Manure water washed from the manure heap is liberally supplied even when the Vines are starting, and this in some measure accounts for the strength of the young shoots even in the sunless season. All Vines planted in this establishment are home-grown, and by this means the desired kinds are always sure to be obtained true. The young Vines in a house planted last autumn twelvemonths now look very promising, the canes being as thick as a good-sized walking-stick, and will this year be allowed to carry a moderate crop. Alicantes grafted here on stocks of Muscat of Alexandria have turned out very satisfactorily, yearly bearing large and perfect crops of fruit. Whenever a house of Vines is found to be on the decline in bearing qualities, it is speedily replaced by younger plants, half-measures, such as trying to recruit old canes, being to growers for market, simply a waste of time and money. Vines here are well treated; they are expected to bear heavy crops, and to furnish the market with fruit of the first quality; if they fail to do this, they are immediately removed. S.

NOTES OF THE WEEK.

IMPROVEMENTS IN PARIS.—Never even during the busiest time of the Empire were improvements being more actively carried out than they are in Paris at present! Many acres of the central parts of the city, covered with costly and massive houses, are being cleared away with a view to the erection of new boulevards. The activity is equally evident on both sides of the river. The new avenue facing the Opera will be one of the greatest improvements effected in Paris. Numbers of men are busy on the sites of the Great Exhibition of next year, and the public gardens are in perfect keeping, which would hardly be expected after the late war and all its disastrous consequences.

WINTER-BLOOMING WINDFLOWER.—Small tufts of the lovely blue-flowered *Anemone blanda*, growing on raised beds in deep sandy loam in Mr. Barr's seed grounds at Tooting, have been producing abundance of flowers for these two months past, and are still very attractive. Where warm, well-drained borders exist, hardy winter-flowering plants of this description can scarcely be too extensively planted.—S.

SOPHRONITIS VIOLACEA ON CORK.—This little Orchid is beautiful under any circumstances when well flowered, but when grown on large pieces of Virgin Cork, its blossoms are set off to unusually good advantage. Plants of it growing in this way in Lord Londesborough's garden at Nottiton are at present very effective, being loaded with richly-coloured, *Crocus*-like blossoms.—S.

THE LARGE-LEAVED SANIFRAGE IN JANUARY.—*Saxifraga crassifolia* is now, probably owing to the mild weather, very beautiful in the Paris gardens. A tuft of it rooted at the base of a Bamboo in the Parc Monceau is in perfect bloom—the flowers, like bunches of Peach blossoms, half-hidden among large glossy leaves.—V.

ORCHIDS IN FLOWER AT FERNIEHURST.—The following are just now in excellent condition, viz., four plants of *Cologyne cristata*, each of which bears on an average forty flower-spikes, and on each spike there are five flowers, making 200 on each plant; *Cypripedium villosum* bears thirty-two flowers, and smaller plants of it each fifteen flowers; *Phalenopsis Schilleriana* has several branched spikes 2 ft. and 2½ ft. long; and on a large plant of *Odontoglossum Halli* there are six fine spikes 3 ft. long.—E. C.

STATE OF THE STREETS AND BOULEVARDS IN PARIS.—In London now gigantic pitch-pots make parts of the town almost unbearable in preparing for worse evils to come—rotten wooden roads. In Paris at present roads of all kinds are in the most perfect condition of repair, and offer all the convenience that could be desired. The excellent Macadam roads are nearly as smooth as asphalt, and less noisy than it or wood, while they are also dry and clean. Roads with a wide space of Macadam in the centre have frequently stone pavements on each side. These pavements suit the heaviest kind of traffic, and do not require repairing so often as the Macadam centre. Bridges and other points that have to bear a very heavy traffic are also paved with stone, which is probably the best plan for such places. The narrower and more crowded streets are coated with asphalt, which

is easily kept in perfect repair, no pitch-pots being necessary, as the dry asphalt is brought to the spot in a heated state and quickly pressed into its place. As the water runs along in the channel on each side, it quickly carries away the dust, &c., swept from the centre or from the pavement.

"THE WILD FLOWERS OF AMERICA."—The first number of an important work on this subject, by Dr. G. L. Goddard, Professor in Harvard University, with coloured illustrations by Isaac Sprague, has just been issued. It contains figures of five species in four plates, and the plates are accompanied by a botanical description, together with some gossip about folk-lore and popular names. The scarcity of figures of even the commoner American plants will render this a welcome work.

CRINUM CAPENSE AS A HARDY HERBACEOUS PLANT.—In Major Trevor Clarke's interesting note on hardy *Crinums* (p. 51), he says that *C. capense* is well worthy of culture as an aquatic, and so it is; but it cannot be too well known that both the pink and white forms of this fine plant are, in various parts of the south of England, among the most valuable of border flowers, even in cold soils. They flower long and profusely in sheltered spots, and have a fine stately habit. I am acquainted with a tuft of it which has survived the hardest winters during the past twenty years. Few plants are more worthy of being isolated on turf in deep, rich soil.—V.

CHURCHYARD GARDENS IN ST. PANCRAS.—In 1875 the Vestry of St. Pancras succeeded in obtaining an Act of Parliament with reference to two open spaces, comprising together an area of about 9 acres, known as the disused burial-grounds of Old St. Pancras and St. Giles's-in-the-Fields, which gave them powers to lay these grounds out as an ornamental garden and recreation ground for the public in perpetuity. Pending other negotiations, the Vestry have determined that the acquired space shall be available for the use of the public in the ensuing spring. A sum of £3000 has been voted for laying out and planting the grounds, and of this amount from £1000 to £1500 is to be expended in trees, shrubs, and appropriate flowers. The grounds will be intersected with gravel paths, and there is to be a good supply of seats.

WHITE WINTER-FLOWERING MULE PINK.—Plants of this Pink named Marie Parc, growing in Messrs. Rollisson's nursery at Tooting, are now producing fine strong spikes of pure double white blossoms. The plants in question were put out in beds in spring, from which time they have never failed to produce quantities of flowers. The blooms now open are of course not so large or so pure in colour as those produced during summer, but had the plants been afforded the protection of a frame or hand-light, they would doubtless have been little inferior to them. For furnishing cut flowers at nearly all seasons of the year, this plant is very valuable, the flowers being almost as large and double as those of a Carnation, and they are produced in much larger quantities.—C. W. S.

WEST INDIAN MANGOES.—A small sample of these delicious fruits was received in good condition during the past week by Messrs. Webber & Co., of Covent Garden, and it is not improbable that Mangoes, together with the Mangosteen and other choice products of the tropics—which it has hitherto been deemed almost impossible to import, except in a preserved state—will be as readily obtainable as Bananas and Pine-apples. The Mango is one of the most variable of all tropical fruits, the best kinds being in India grafted on common sorts as stocks, just as are our Apples and Pears at home. We noticed two varieties in Mr. Webber's importation, a small yellow and a large green kind, and the latter was especially delicious in flavour, and as large as an Easter Beurré Pear. The skin is smooth and of a yellowish-green colour; the flavour of the soft yellow pulp (surrounding a fibrous-coated stone) is like that of a juicy Nectarine mixed with Pine-apple, and now and then there is just the faintest trace of turpentine left on the palate. At present there is no regular importation of these fruits, but judging from the sample we have just seen, there seems no reason why some method could not be devised by which they might be regularly imported.

SPRING GARDENING AT THE WESTMINSTER AQUARIUM.—The beds here are just now very effective, being tastefully filled with early-flowering plants, especially two beds round the fountains at each end of the nave. These early flowers, consisting of Hyacinths, Tulips, Primroses, Lily of the Valley, and others, are not in patches of two or three merely, but in groups, an arrangement which greatly adds to their effectiveness. It is stated that during the past twelve months, in addition to the permanent beds, Mr. Wills has planted out something like 40,000 plants. The permanent subjects, such as Tree Ferns, Palms, &c., present in many instances an unhealthy appearance. The multiplication of gas jets has increased the aridity of the atmosphere, and the abolition some time since of the daily practice of watering the floor of the building, has also had an injurious effect on the plants.—R. D.

OLD-FASHIONED TABLE BOUQUETS.

THESE used to be made up of sweet-scented flowers and fragrant leafy spray, but unfortunately they are now so much things of the past that the sight of one would be quite a relief compared with the densely-packed, Mushroom-shaped bouquets of our own time. The old posy chiefly consisted of a handful of bright flowers and fresh green leaves, while one of its principal charms was the total absence of all the so-called modern art of the bouquetiste in its arrangement. No delicate blossoms from conservatory and greenhouse were there, but in their places we had Clove Pinks, Carnations, white Lilies, Sweet Williams, scarlet Fuchsias, sprays of Honeysuckle and branches of fragrant Rosemary, Southernwood, and Sweet Brier, intermixed with Moss Rose buds and Cabbage Roses. These were arranged as they were cut, a Rose bud here, and a spray of Mignonette or Jasmine there, each flower having a fair accompaniment of its own foliage, so that colour was balanced

An Old-fashioned Table Bouquet.

and toned down by fresh greenery. In an arrangement such as this individuality of form was well brought out; and a graceful combination, such as that represented by the annexed illustration, was the result. B.

GARDENS OF THE VILLA FRANZOSINI.

THE Lago Maggiore is certainly one of the places most visited by tourists travelling in Italy, notwithstanding which its varied beauties are but little known. Those who have paid a hurried visit to the Borromean Islands consider that they have done their duty; but those who, while stopping at the Grand Hôtel Pallanza, can spare some days for the lake and visit the Villa Franzosini, will certainly not regret the delay occasioned thereby. It is strange that a contemporary, which has lately described at length the Borromean Islands, Fratelli Rovelli's nursery, and given minute descriptions of the Villa Troubetzkoy, has hardly mentioned the Villa Franzosini, which is by far the most beautiful place on the Lago Maggiore, and not only one of the most beautiful villas in Italy, but perhaps in Europe. The Isola Madre can undoubtedly boast of more exquisite views and plants of equal age, but it must succumb to the Villa Franzosini in the development, culture, and collection of its plants, and the general state of the garden.

The Villa Franzosini strikes one by its surprising vegetation. Surrounded, as it is, by hills placed at not an oppressive proximity, it is protected from all winds descending from the

Alps, which makes it the most delicious spot imaginable for a winter residence, and Violets, Camellias, Daphnes, Edwardsias, and Calycanthus succeed each other without interruption from October to April, when Azaleas, Rhododendrons, Roses, &c., come in to take their place. Maréchal Niel Roses climb the walls in profusion, and flower throughout the winter. I have seen many English ladies returning from the Villa in the months of December and January laden with beautiful Roses and Violets, picked before them in the open air, and Camellias of such size and beauty, as to surpass even horticulturists' specimens. The peculiarity of the climate of the Lago Maggiore is, that it is as favourable to vegetation in summer as in winter, for we see Camellias, Azaleas, Rhododendrons, Agaves, Oranges, Lemons, Metrosideros, Gardenias, Conifers, and many other plants thriving well here, whereas at Naples and Nice some of these are destroyed by the heat and drought of summer. The moisture produced by the vicinity of the lake diminishes the effects of the slight frosts of winter and the heat of summer, not to mention the frequent and abundant rains in summer, which impart such vigour to the plants as to enable them to resist all excesses of temperature. Mr. Linden, who has travelled a good deal, was so much struck with the marvellous vegetation of the lake, and of the immense variety of plants which thrive there, that he determined to set up a horticultural establishment at Pallanza. Unfortunately the law forbidding the entrance of plants from abroad, caused by the fear of the Phylloxera, has for the present prevented the full development of this scheme. One part of the Villa is very old, and was bought by Mr. Franzosini from Prince Poniatowsky, the other half was planted by the present proprietor, with trees almost all sown by himself, about twenty years ago, and their progress has been such, that the difference of age of the two growths is scarcely perceptible. There are about 2000 Camellia trees, the largest of which is 24 ft. in height, and 65 ft. in circumference, not having been planted more than twenty-one years, and there are many others of the same size. When Roezl visited this Villa some years ago, he said that he had not seen Camellias of such a size, even in Japan. There are numbers of Magnolias, amongst which are some glorious specimens, the largest being 48 ft. in height, and 114 ft. in circumference, the trunk being 9 ft. in circumference. This tree is forty years old. There is a Magnolia fuscata 18 ft. high, M. Hartwegi 21 ft. high, and a fine specimen of M. Campbelli, A Wellingtonia gigantea sent from London by Messrs. Veitch, in 1858, only 11 in. high, has now reached 50 ft., and has ripened seed this year; a Cryptomeria elegans, 21 ft.; a Laurus Camphora, 49 ft.; a Laurus glandulosa, 51 ft.; a Laurus regalis, 17 ft. high, and a Phœnix dactylifera, whose trunk without leaves is 11 ft. high. Without tiring your readers with further description, I will only add the names of some of the most remarkable plants growing there. There is a very large collection of Conifers (amongst which are some magnificent Mexican Pines, which astonished Linden and Roezl), Cypresses, and Abies of all kinds, Retinosporas, Thujas Torreya, Dammara Browni—all beautiful specimens, which, enchant all connoisseurs. Amongst Palms there are splendid Chamærops of different varieties, a beautiful specimen of Jubæa spectabilis, Sabal Adansonii, Cocos australis, several varieties of Phœnix, a large collection of beautiful Agaves, (amongst which A. Franzosinii is very striking), Dracæna indivisa and lentiginosa, Doryanthes excelsa, Bonapartea gracilis, glauca, and juncea, Cycas revoluta, Gunnera scabra and manicata, several varieties of Phormium, a splendid collection of Bambusæ, Rhus sneecedanea, Cerasus Capolini, Illicium anisatum (now all bearing fruit), Piper Fitocatzura, &c. For some years there have been Balantium antarcticum and Xanthorrhæa grandis growing there, which are succeeding perfectly. The name of the head gardener of this Villa, who has sown and cultivated these plants, is Signor Paolo Cazzaniga.

DELLA VALLE DI CASANOVA.

Abutilon Boule de Neige.—This is the best of the Abutilons. Its flowers are large and white. It blooms throughout the whole year, and therefore is alike desirable for the conservatory or garden. Its growth is rapid—small plants attaining, according to a writer in "Moore's Rural," the height of 5 ft. during the summer months. In autumn it may be cut back to any desirable size and potted for the winter, when it will quickly recover its symmetry and resume its ever-blooming habit. Its quick and exceeding popularity is a sufficient guarantee of its merits.

THE FRUIT GARDEN.

KEEPING LATE GRAPES.

DURING the autumn and winter months the keeping of Grapes in good condition for dessert is frequently more perplexing than their culture up to the period of ripening, principally from the following causes:—(1) From growing sorts not adapted for late keeping; (2) from not having the roots under control; and (3) from having the fruit indifferently matured. Selection of sorts is of the utmost importance; for it is quite as easy to have Lady Downes and similar varieties in good condition late in spring, as it is to have Hamburgs and other thin-skinned varieties presentable at Christmas. Yet in numerous places, more especially those of limited extent, little attention is paid to selection, and the consequence is that when little artificial heat is applied, the crop is no sooner ripe in autumn, than, on account of the heavy rains falling on unprotected borders and the atmosphere (which is usually moist at that season) mouldiness of berry, and mildew on the leaves make great havoc with the crop, which, instead of furnishing a supply for several months, is obliged to be consumed or got rid of in as many weeks. There is, however, no lack of kinds that will keep well, such as several varieties of Muscats, Lady Downes, Alicante, Barbarossa, Raisin de Calabre, and similar sorts, which when fully matured excel in sweetness many of the more luscious summer varieties; but the flesh is firmer and the skin is thicker, properties to which they owe their good keeping qualities. In the event of a new Vinery being erected it is better to have two small houses than one large one, in order that distinct treatment may be given to early and late sorts; for, whereas Hamburg, Sweetwater, and Muscadine may be grown in perfection with little artificial heat, most of the late kinds require a good supply of heat to prepare them for keeping a long time; the bunches should also be thinned much more than those of early sorts. But in the event of requiring to substitute late sorts for early kinds in established houses without losing a crop, the readiest method is inarching on growing shoots at the base of each Vine which it is wished to change. This operation is easily performed as follows:—Procure the required sorts of Vines in pots one year old, cut them back close in winter, and in spring start both about the same time, or in preference, the scions a little earlier than the stocks to be operated on; and when the shoots are about 1 ft. long, place the pots close to the base of the strongest shoots; take a slice off both stock and scion, so that when bound together the edges fit exactly; if a tongue be cut in the scion, and let into a slit in the stock, a union will be more rapidly effected. The stock should be stopped at one or two leaves above the graft, which should be trained up near the glass. When the union is effected, the scion should be gradually severed from its own roots, and it will be, if all go well, by the end of the growing season a strong fruiting cane fit to bear several bunches of Grapes the following season, and by thinning out the oldest rods by degrees, an entire change of varieties may be effected in about three years. Almost any kind grows freely, and many sorts are greatly improved by being worked on the Black Hamburg. For trying seedlings or any new sorts, I always adopt this plan in preference to planting young Vines in old borders. Protecting Vine borders from excessive rainfall is also a most important matter in the case of late Grapes, and many contrivances are resorted to for this purpose. Wooden shutters and light framework covered with oilcloth carry off the rain, but they exclude sun-heat, so that when practicable, glass lights are best. Any close coverings, such as leaves, Ferns, &c., require some waterproof covering in addition, for by excluding light and air they make the borders more sodden than if they were entirely unprotected. I have here a good illustration of the effects of inside borders in the case of an old Black Hamburg Vine on the back wall of a Muscat Vinery. In this case, the roots run under a paved pathway, where there is no opportunity of giving much root moisture, and yet no difficulty is ever experienced in keeping the fruit in good condition longer than, to all appearance, better fruit on Vines growing in outside borders. An exaggerated importance is often given to size of bunch and berry, to the exclusion of equally important points of culture. If size

were the only point to be arrived at, rich borders and plenty of root moisture at all seasons would doubtless be desirable; but there can be no question that moderately large bunches, well ripened, are preferable to large ones for late keeping. Grapes are much more extensively grown for use than for exhibition, and bunches weighing 1½ lb. to 2 lb. each, and plenty of them, are what the majority of cultivators require. With carefully selected varieties, grown in a light, airy house, with a command of heat sufficient to ensure a light, buoyant atmosphere, the roots entirely under control as regards moisture, and the borders made of good loam, and manure sparingly applied, the bunches will be of medium size, but of the finest quality.

Henham.

J. GROOM.

SCARCITY OF COMMON FRUIT.

THE paper read by Mr. Bartley before the Society of Arts on the above question, and given in THE GARDEN (p. 41), is of the greatest importance to the bulk of householders, for the scarcity and dearth of common fruit make a great inroad on their incomes when limited. There is little doubt but that Mr. Bartley's paper must convince every one that, by increasing the production of common fruits on waste lands, commons, and hedgetows, more abundant supplies could be sent to the markets, and at a cheaper rate. Without entering into the statistics of how much might be done by utilizing railway embankments, waste lands, and commons for fruit growing, my object is simply to give lists of the varieties of common fruits which I believe to be best adapted for bringing in large returns on account of their hardiness, freedom in bearing, and general good qualities for use. My experience of fruit growing in the Midland Counties has a range of forty years, and all the varieties which I intend noticing I found best for growing on all soils and situations. To begin with the most valuable and wholesome of all common fruits, the Apple, which, next to that useful vegetable, the Potato, is the most worthy of increased production. With the Apple this can only be done when the trees are grown on free stocks, for, although on dwarfing stocks finer fruit can be grown in orchards and gardens, where experienced cultivators attend to their wants by judiciously pruning and manuring them, yet they never could furnish a sufficient supply of fruit for the million. If Apple trees on the free stock were planted on waste lands, railway embankments, and in cottagers' gardens, to a greater extent than at present, there is not the least doubt but that our importation of foreign Apples would be greatly reduced. There would be no occasion for great expense being resorted to in trenching the ground when planting the trees, for the Apple is very accommodating, and grows well where the ground is covered with Grass, or even where the soil is hard and stony; but on gravelly sub-soils the roots often canker, and trees planted on such are, as a rule, unproductive. Of course, where Apple trees have been planted in orchards, where the soil has been properly trenched and drained, and attention paid to pruning, and plenty of manure has been applied to other plants near them, their production of fruit will be greater and finer than on land where these advantages have not been experienced. The following is a list of some of the common fruits, which I believe will be found to be suitable for growing in quantities for a better supply to our markets in the different months, divided into early mid-season and late kinds.

APPLES.—*Early kinds*—Astrachan, Irish Peach, Keswick Codlin, and Hawthornden. *Mid-season kinds*—Lord Suffield, Dutch Mignonne, King of the Pippins, and Cox's Orange Pippin. *Latest and most valuable kinds*—Blenheim Orange, Alfriston, Damelow's Seedling, and Starmer Pippin; and if quantities of only three varieties of the different sections were selected for planting, I should recommend Lord Suffield, Blenheim Orange, and Starmer Pippin.

PEARS.—*Early kinds*—Beurré Giffard, Clapp's Favourite, Beurré d'Amanlis, and Williams' Bon Chrétien. *Mid-season kinds*—Louise Bonne of Jersey, Doyenné du Comice, Thompson's, and Marie Louise. *Latest-keeping kinds*—Winter Nelis, Josephine de Malines, Bergamotte d'Espéren, and Beurré Rance.

PLUMS.—Some varieties of these might be also more extended in their cultivation by being planted on waste lands, such as the Early Prolific, Rivers' Early Damson, Green and Oulin's Golden Gage, Kirke's, Victoria, Diamond, Prince Engelbert, Belle de Septembre, and Impériale de Milan.

BUSH FRUITS.—Of the various small bush fruits, the supply might be increased to an immense extent by planting Currants, Raspberries, and Gooseberries in uncultivated corners of gardens and orchards. It is surprising what a quantity of Raspberries can be grown in a small space in a suitable light soil made as rich as possible with rotten manure, and never digging amongst them, except to take up

the running canes when too numerous. Black and Red Currants should be treated in the same way, for they all root near the surface, and their fibres should never be disturbed by digging near them, only adding some manure to them every year. The greatest error in growing Gooseberries when quantities are required is the severe winter pruning usually given them; all the pruning they require should be performed in the spring, when all danger from birds attacking their buds is over, and then only some of the branches in the centre of the bushes should be thinned out, without spurring the young shoots to raise a lot of spray for another year.

Welbeck.

WILLIAM TILLERY.

BEARDED GRAPES.

DODDERS are described as leafless vegetable parasites, maintaining their existence by twining round other plants, into the stems of which they insert their sucker-like roots. In appearance they simply resemble numbers of fleshy threads. Both in this country and abroad they are pests to Flax and Clover crops, but occasionally they adopt other plants as foster-parents, and in some localities attack the Vine with the curious result represented by the accompanying sketch. In this case

Bearded Grapes.

the Dodder affixes itself to the berry, living and thriving so well on its juice, that it frequently forms a tassel or beard hanging down from each bunch 4 ft. in length. That the Dodder's appearance on the Vine is due to one of its seeds falling on the fruit or other part of the plant, and there germinating, would seem scarcely probable. The much more likely explanation is, that the parasite has spread from Clover grown between the rows of Vines, this method of cultivation being a common one in South Tyrol, where bearded Grapes are most frequently met with. According to a communication from Baron Hausmann to the Vienna Zoologisch-botanische Gesellschaft, the peasants of Bozen, Eppan, and Salern, in the country just named, sometimes amuse themselves by twisting the stems of the Dodder round a neighbouring bunch of Grapes, and thus what might be taken for a freak of Nature is in reality not so, but the result of artificial intervention. In any case, judging by past experience, no fear need be entertained of the Dodder assuming the character of a Vine plague, or bearded Grapes becoming anything more than a curiosity.

T. S.

Mrs. Pince's Black Muscat Grape.—Mr. Smith, of Waterdale (see p. 39) has apparently struck the right point as regards colouring this Grape, which doubtless should have the best part of the year in which to ripen. It is a Grape with which I have not had much experience, but I have recently seen two Vines of it in a late

house, in which its foliage was in fresh condition, while that of Muscat, Alicante, and others was nearly all shed. It, therefore, seems reasonable to suppose that a Vine, which is late in shedding its leaves, will also be late in ripening its fruit; at any rate a Vine, whose leaves remain long in a green state, will also be late in ripening its wood.—ROBERT MACKELLER, *Abney Hall, Cheddar.*

Foster's Seedling Grape Best when Shrivelled.—This Grape is noted as an early and abundant-bearing sort rather than as in any way remarkable for its flavour. On the former ground it is not unusual to include one plant at least as worthy of a permanent position in the early Vinery, and as it almost invariably leads the van as regards ripening, it generally receives a due amount of appreciation. During the past summer at Tranby Gardens in this neighbourhood, where a range of Vineries has been recently erected, a couple of very fine bunches of this Grape were sent in for dessert, but though full ripe in the ordinary acceptation of the word, they met with such scant favour that the following day the gardener had instructions to remove the Vine and to send no more such flavourless Grapes in for dessert. There were several more bunches on the Vine, and there they hung for some six weeks longer, when they assumed a darker colour and began to shrivel. Of course Hamburgs had got into good cutting condition long before this, and were so much more appreciated that the doom of Foster's Seedling was all but sealed. One day, however, the gardener tasted one of the shrivelled berries, and to his surprise found that it possessed a delicious flavour; so much, indeed, was it improved, that one could not recognize it as the same Grape. He thought he could not do better than put it to the test again, so on the same day he sent in a bunch for dessert, and the first inquiry the following morning was—"What was the name of that delicious Grape sent in for dessert yesterday; it was new to all the company?" The reply was that it was none other than the condemned Foster's Seedling. I need only further add that a reprieve was at once granted, accompanied by instructions to plant another Vine of it. Possibly a knowledge of this fact may be of value to Grape-growers.—JAMES C. NIVEN, *Botanic Gardens, Hull.*

Peaches in Pots at Llanover.—The following is a list of Peaches grown in pots in a cold orchard-house here, viz.:—Hale's Early.—This ripened first. It is an excellent Peach, the fruit of which is usually good in quality. Early York.—This is likewise a good Peach, but not quite so early as Hale's, nor is its fruit so large, but it is good in quality. Early Beatrice.—With me the flavour of this was very inferior compared with that of other kinds; I, therefore, only grew it one year. Grosso Mignonne.—This is one of the best of Peaches for pot culture. It is a free bearer, large in size, and excellent in flavour. Noblesse.—This is a handsome Peach, and I have seen it do remarkably well, but here it is very indifferent. Crawford's Early.—This is a magnificent Peach, large in size, and excellent in flavour. Royal George and Royal Kensington are grand in every respect. Barrington is also a very handsome Peach, but a shy bearer, and liable to split and drop. Stump the World is a fine Peach of high quality, very prolific, and one which should be in every collection. Princess of Wales is one of the best Peaches in cultivation, very handsome, and excellent in flavour. Wallbrton's Admirable is well known to all who appreciate a good late Peach; of this I gathered four dozen of medium-sized fruit from one tree. Of Neefatines, I grow Lord Napier, Elruge, and Pitmastou Orange.—E. M. DAVIES, *The Gardens, Llanover.*

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Moss on Fruit Trees.—"J." asks (see p. 59) how to destroy Moss on fruit trees? Owing to the dampness of the climate in Cornwall both fruit trees and other deciduous trees are often covered with Moss, for which I have found fresh wood-ashes the best cure. Some years ago I used lime, but finding it injurious to Rhododendrons and Camellias, I tried wood-ashes, and found them most effectual in destroying Moss; I, therefore, have used nothing else since.—THOMAS T. BOSCAWEN, *Lumoran Rectory, Probus.*

Early Strawberries.—Mr. Groom tells us (see p. 47) that we cannot get ripe Strawberries, to have a true Strawberry flavour, before the first week in March. Thirty years' experience has taught me that we cannot get them really well flavoured before the first week in April.—K. S.

Free-bearing Pears.—Allow me to inform Mr. Fish (see p. 47) that I placed Bergamot Espere second on the list, on the supposition that I had to grow but two kinds only; of course as other kinds were added, this variety would descend in the list considerably. Our trees of it are on the Quince stock, and occasionally there is the slightest trace of grittiness in the fruit, but I consider that its general excellence and productiveness more than counterbalance that.—W. WILDSMITH.

Strawberries Losing their Foliage.—All kinds here, I suppose from the excessive rains, have either lost their foliage, or it has turned brown, with the exception of that of Laxton's new Strawberry Pioneer, which is glossy and quite fresh, thus showing that it has a good constitution. This variety received a first-class certificate at South Kensington in July last.—R. GILBERT, *Burghley.*

COTTAGE GARDENING.

Cucumbers.

To CUCUMBERS under glass I have previously alluded in my remarks on turf-pits, but not with sufficient detail. Unless the resources in the way of heating materials are almost unlimited, the end of February or early in March is time enough to begin; and if only two or three plants be required for a small frame or pit, it will be better to buy them, as they can usually be obtained at 1s. each, and be brought home just at the time the bed is ready to receive them. If the plants have to be raised at home, a small seed-bed should be made early in February for raising the young plants, and the making of the main bed must be so timed as to be ready just when the young plants are fit to go out. If a hotbed and frame be used for their culture, the bed should be 4 ft. or $4\frac{1}{2}$ ft. high at back, gradually sloping down to 3 ft. at front. If built on sloping ground it will be an advantage, as then it might be of equal thickness. It should also extend considerably beyond the frame on all sides—1 ft. will not be too much—and there will be no occasion to put linings to it to keep up the heat if the bed be not put up before March. Stable manure and tree leaves in something like equal proportions are well suited for hotbed-making, and if well mixed together ten days or a fortnight before required for use, no further preparation will be necessary; but if manure fresh from the stable alone be used, a longer preparation will be required, in order to get it into a thoroughly sweet condition before the bed is made up. Should this operation be neglected, the bed will probably be so hot that nothing can be put in it for some time with any chance of success, and then the heat will decline suddenly, and the bed will require to be lined with warm manure to restore it to the requisite temperature. In making up the bed some pins should be taken to apply an equal amount of pressure all over it, so that it may settle evenly, neither making it so solid as to prevent fermentation, nor yet leaving it too loose or open, as in that case the fermentation would be too rapid. A medium way as to firmness is best, and will be found to produce a regular steady heat for the longest period, and this is undoubtedly the most essential point. A small one-light frame, 5 ft. by 3 ft., will be quite large enough to raise the young plants, and if 6 in. or 8 in. of sawdust or Coconut refuse be placed inside the frame the seeds may be sown without loss of time. There is no better plan than sowing the seeds singly in small pots and stopping them when they have made the second rough leaf, and if the bed be not ready to receive them put them into 48-sized pots rather than allow them to become pot-bound or starved; for checks of this kind are more injurious to early Cucumbers than later ones, when more light and sun-heat are available. When the main bed is ready for the plants put one good barrowful of soil in the centre of each light: turfy loam slightly enriched is the best. It is a common error to use too rich and too light a soil, the consequence being the filling of the frame with weakly, long-jointed growth, but with a paucity of fruit, and those few will, in all probability, turn yellow and refuse to swell. A very thin stratum of soil is sufficient to start with; 3 in. in depth will in most cases be ample. If there be any danger of the heat rising too much, a layer of turves may be placed under each hill, and 2 in. of soil may be placed over the bed to keep down any noxious gases that may be evolved; but if the bed have been properly made there should be no danger to apprehend from this or any other source. Although, as I have previously stated, no great depth of soil will be required when the plants are put out, yet as soon as they begin to grow the white roots will come out on the surface and will require sprinklings of fresh, warm soil, once or twice a week to cover them through the growing season. Later on, when the plants are in full bearing and may perhaps be showing signs of exhaustion, a top-dressing of short, mellow horse-manure will be beneficial. Many small growers allow the shoots to grow too long before stopping; this is a great evil, as it fills the frame with a quantity of useless material, and necessitates severe pruning. There is only room in a frame for a limited number of fully developed leaves, and if too much growth be encouraged it induces a weakly habit, the foliage becomes thin and poor, and ultimately turns yellow and decays.

In a well-managed Cucumber frame the knife should not be much required; in fact, only to cut the fruit. The finger and thumb will do all the necessary pruning if used in time. All shoots should be pinched one joint beyond the fruit; to leave more only needlessly crowds the foliage. In the matter of ventilation, so long as the atmosphere is sufficiently charged with moisture, Cucumbers thrive in a close, warm place. As a rule, it is a safe plan to give a little air at the back, early in the morning on bright and warm days, gradually increasing it up to eleven o'clock; and syringing with soft, tepid water about half-past two or three, or later according to the season of the year, and close the lights at the same time. Cucumbers, like all other plants when out of health or in a weakly condition, are liable to be attacked by various insects and fungoid parasites, and the main object—viz., the healthy development of the plants—should be always kept in view, and will be secured by using fresh, sweet, healthy soil, by having everything in and about the frame, pit, or glass, scrupulously clean, by always keeping the growth moderately thin, not allowing the frame to become choked with growth, for this is a sure way of breaking down the constitution of a plant, and bringing it into the condition that renders it liable to become a prey of insect or other pests. There is always a very close relationship between cause and effect. For instance, if red spider attack a plant, it indicates a lack of moisture either in the atmosphere or at the root, or perhaps both, and if attended to in time, by giving plenty of moisture and a close atmosphere for a few days, the enemy will be easily overcome. If the foliage be spotted with mildew, it is generally a sign of stagnation somewhere, either at the root or in the atmosphere, and whilst the necessary remedies are applied—in this case dusting with sulphur—the cause should be removed; and so it is with aphides: if we could go back to first causes, we should find that their presence was in many cases due to some check sustained by the plant, which had perhaps at the time passed unnoticed, or had been forgotten. There is another disease of a gangrenous character to which Cucumbers are occasionally subject that is probably due to deficient action or circulation of the sap in the plant somehow, the true nature of which is hardly yet understood. Stamping out in this case appears to be the best remedy. Fumigation with Tobacco is the best remedy for green fly and thrips, but it must be done with care, for if the Tobacco be allowed to blaze or flare, some, if not most, of the leaves will be scorched. Fumigation must only be attempted when the foliage is perfectly dry. I need hardly say that mats or warm covering of some kind must be placed over the glass every evening till July, nor yet that all water in all the early stages of growth must be raised to the temperature of the frame before use. One way of managing this will be to keep a pot full in a corner of the frame. I have found no better Cucumber, all things considered, than the Telegraph, either for hotbed or house cultivation.

E. HOBDAY.

Age and Leafing of Trees.—According to Professor Decaisne, of Paris, and Professor Carnel, of Pisa, it would seem that age has nothing to do with the date of the leafing of trees. In some cases the old and young trees of the same species burst their buds at the same time, while in others the older, in others the younger, developed their leaves first. But the most valuable and original material for affording some light on this subject was "a series of observations made upon two trees of the same height above the ground during fifty-seven and sixty-eight years respectively." These observations were made upon two Horse Chestnut trees at Geneva, and are regarded by M. A. de Candolle as perfectly trustworthy. The average date of the leafing of the one longest under observation is 91.9 days after January 1, and of the other 93.61 days. Dividing the whole term into six, four, or two periods of equal duration, the average dates exhibit no essential progression or retrogression. But it is worthy of remark that during the third period of seventeen years, 1812-58, the average is 2.5 days later than during the fourth period, 1859-75. Observations on a Grape Vine by Messrs. Macleod and Lanezweert at Ostend, from 1843 to 1875, indicate a gradual forwarding of the date of leafing. Thus, during the first period of sixteen years the average date was 16.6 days later than the average of the succeeding seventeen years; but De Candolle thinks this may be due to diminished vigour or pruning and other artificial conditions.

CHANTILLY.

THIS noble old French demesne, now barely known otherwise than as the Ascot Heath of the Continent, contains some of the finest woodland and forest scenery to be found within a thirty-mile radius of Paris. Originally a wild forest, affording game in abundance, it was long a favourite hunting-ground, and doubtless that led to the establishment of the magnificent chateau of which that represented in the annexed engraving is but a fragment. Some five or six years ago, however, preparations were being made to restore this old hunting palace of the Princes of Condé to its former greatness. The gardens are extensive, but, owing to the place having long been confiscated and the chateau unoccupied, they have been much neglected. The principal charm of the place as it at present exists is its thousands of acres of forest, through which shady walks and hunting paths extend in all directions for miles. Here may be seen excellent examples of Oak, Beech, Elm, Poplar, Lime, Acacia, and other deciduous trees intermingled here and there with the more sombre tints of Pine, Fir, Yew,

and a few other Conifers as well as other evergreens. The broken fringes of the great forest, stretching away as far as the eye can reach, are very beautiful, especially when clad in rich autumn tints. The chateau itself is partly surrounded by water, and about three miles from it is a small lake and an antiquated, turreted chapel, which although not exhibiting any particular architectural beauty, is especially attractive as the centre of some very beautiful and varied tree and water scenery. Here during the warm summer evenings may be heard the united melody of countless numbers of nightingales, which congregate in this sheltered spot. A few red and fallow deer may also at times be seen in the open forest glades, and the lakes near the chateau are well stocked with carp and other fish, which come quite close to the bank to be fed. The gardens and grounds are open to the public on Sundays and fête days, and the forest itself is intersected by public roads, one of which leads to Morte Fontaine, where there is another old chateau; this latter is, however, comparatively unimportant, and is principally interesting to horticulturists on account of its containing the nurseries of MM. Chantrier, where thousands of Dracenas, Ficuses, Ferns, and other deco-

orative plants of that kind, as well as Roses and fruit trees, are grown for the Paris markets. The village of Chantilly itself contains several hundreds of English residents, who have here and there some pretty gardens, and in the spacious yard of the Hotel de France several large Oleanders were, when I saw them some six years ago, literally masses of rosy flowers, and an old shed close by was completely covered with the rambling branches of *Bignonia radicans grandiflora*, some of which were literally wreaths of crimson flowers and fresh green leaves. This last-named plant and the Oleanders, indeed, seemed perfectly at home near Paris, where the profusion of flowers which they produce is doubtless owing to the dry, hot autumnal weather thoroughly ripening their wood. F. W. B.

Frame Coverings.—The coverings alluded to by Mr. Cornhill and "W. N." (see p. 40) do not possess the lightness sought for by "South Italy," as if made of straw, even in the most careful way, they will absorb and retain moisture until they become both heavy and valueless. What straw protectors could have withstood the

Chantilly.

recent wet weather for any length of time without becoming saturated? What is required is a kind of protector that is at once strong and light, and that will be impervious to moisture. Probably the most serviceable and enduring would be one constructed with sides and ends $2\frac{1}{2}$ in. by 1 in., made the size of the frame lights to be covered; over this crosswise should be nailed a covering of $\frac{1}{4}$ -in. boards, and over this again a layer of any textile material, such as old sacks, pieces of carpets, or other non-conducting material, and then over all a covering of stout oiled calico or canvas. To keep this latter thoroughly impervious to rain, it would be necessary to give it a fresh dressing of oil or other non-absorbing substance every year, but the cost would be trifling compared with the usefulness and neatness of such protectors. Even the straw coverings so commonly used would be all the better if protected from the rain with a dressed covering, and the additional period they would last would more than repay for the small extra outlay.—A.

Fruit as a Medicine.—The regular and moderate use of well-ripened fruit is not so widely appreciated as it should be. Residents in regions where more or less malaria prevail, have, according to a writer in the "Country Gentleman," discovered that nothing is a surer preventive of its deleterious effects than a regular supply of fruit. Fruit will not only prevent disease, but in some instances it has proved one of the best medicines to cure it.

THE KITCHEN GARDEN.

PEAS AND THEIR CULTURE.

VARIETIES of Peas, like all kinds of produce for which there is a large demand, are continually increasing, so that to make a selection from catalogues has become a hopeless task. Starting with early kinds, except for the first few gatherings, the earliest section of Peas is scarcely worth growing when compared with the rich melting flavour of the Marrows that come in later; but as the aim of most growers is to get Peas as early as possible, a sowing is generally made of one or other of the small round kinds. Having tried most of these, my favourite is Ringleader, which, although an old variety, is still one of the earliest and best, a good cropper and very hardy. Laxton's William the First is, however, nearly as early, and, being of better quality, it is a desirable Pea to cultivate. Among Peas which he has raised this is almost the only really useful kind, as most of the others are later sorts, and vastly inferior as regards flavour to others that have been cultivated for many years. The large pods which some of these Peas have were the means of bringing them into notice; but then they are mere wind-bags, and Peas are not worth growing for the sake of their pods, however showy they may be. As a dwarf-growing, free-bearing, compact Pea for sowing on a warm sheltered border, Maclean's Gem is unsurpassed, for not only is it a most prolific bearer, but it is everything that can be desired when cooked. Were I only to grow one kind of Pea, this would be the one, as it has all the good qualities which a dwarf, early sort can possess, and from not being more than about 2 ft. high, a few twiggy sticks suffice for its support, a consideration near towns where Pea sticks are difficult to obtain. For sowing in open quarters to succeed the first earlies, there is none that equals the old Advancer, which is really in every respect a first-class Pea. This variety grows to the height of about 3 ft., branches freely, and bears nearly up the entire length of its haulm a number of well-filled pods, the Peas in which are of good colour and delicious flavour. To follow on the heels of this, a sowing of Veitch's Perfection should be made about the same time, and, where a regular supply is wanted, continued at intervals of a fortnight till the middle of July. Take it all in all, this is by far the best dwarf Pea in cultivation; but one mistake which many make is sowing it too thickly, a circumstance which, on account of its robust free-branching habit, causes the haulm to become so thick and crowded as to spoil the crop. In good, rich, deep soils—and, if it can be avoided, Peas should not be grown in any other—this variety should rather be planted than sown, as the seeds ought not to be nearer each other than from 1 in. to 2 in. Unless collections are desired, the kinds just named are sufficient, as far as dwarf sorts are concerned, for any garden; and they are varieties which will be sure to give satisfaction; but where room can be spared and stakes obtained, then I would recommend every one to grow *Ne Plus Ultra*, a truly grand Pea and perfect in every respect. This, too, should be sown thinly, and, if possible, at intervals of 10 ft. apart, as then both sides of the row get plenty of light, and heavy crops of large well-filled pods are the result. Besides the convenience of gathering and a great increase in the yield, raising Peas at wide distances apart has other advantages, such as affording suitable shade to Celery, Cauliflower, and Lettuce, that always succeed much better when so treated than when grown in any other position. As before observed, Peas require a deep, rich soil, and in order to spare unnecessary labour, I make it a rule to sow them where Celery has been growing the year previous and *vice versa*. The advantages of this will be obvious at a glance, as the one prepares the ground for the other. To grow Celery well, the trenches must be heavily manured, of a portion of which the Peas get the benefit, and the deep digging necessary for its cultivation and in taking it up, is just what the after crop requires, as the roots can penetrate far down and be in a measure independent of the weather or other aids for a supply of moisture.

It is to be feared that early-sown Peas this year will be a failure on account of the excessive wet or the exceeding mildness of the weather, which has brought them on so forward that the first frost is sure to cut them off. With the land in

its present state it is useless sowing seeds, as they would only rot in the ground; therefore where very early gatherings are looked for, expedients of some kind must be adopted. The readiest way of getting over the difficulty is to sow in boxes or pans of finely-sifted leaf soil, and to place them in any vacant situation under glass where they can be kept close till they germinate and get fairly up, when they must be set well up to the light and have plenty of air to prevent them from becoming etiolated or drawn, which they soon would do if at all thick. Various other plans have been adopted in raising early Peas, such as sowing on strips of turf and in drain tiles filled with soil, but both take up much more room, time, and labour, and are not one whit better, as Peas transplant just as readily and safely from the leaf soil as when treated in any other way. By the middle of March, if the weather be anything like favourable, Peas sown now as just recommended may be safely ventured out on any sheltered border or quarter, where they may easily be put into rows by drawing a deep drill by means of a hoe or chopping one out with the spade so as to admit their roots without being cramped or doubled up. The fineness of the leaf-soil will admit of their being divided to any extent without injury, so that they can be laid in thinly at the time of planting, and when this is done they should be protected by having a few sprigs of small-leaved evergreens stuck along one side of the row to break the force of any cold winds that may occur.

Sparrows do much damage to Peas just after they emerge through the ground, or when planted out in this way, nipping off each leaf as it appears till the plants are entirely crippled, unless some effectual means be adopted to prevent their attacks. Nothing answers the purpose better than the galvanised wire Pea guards that are now sold so cheaply by most ironmongers, as these put them quite at defiance, and if taken care of when out of use will last a lifetime, so that the first cost ought scarcely to be a consideration, as they do away with all annoyance and disappointment in securing a crop. In cases where these are not at hand, a ball or two of common black cotton run up and down about three times, just above the heads of the rows of Peas, and supported in that position by a few small sticks, will generally keep them at bay, as they become alarmed when they alight and find their wings entangled; or the tops of Peas may be made disagreeable to their palates by sowing some dry soot over them while the dew is still on them, an operation which will also answer the double purpose of preserving them from slugs, which this year are more than usually troublesome, and will be so unless we have some sharp frosts to come upon them unawares before they have time to bury themselves in the ground. Besides the above, growers of Peas have other enemies to contend with, the most formidable of which are rats and mice. After trying many remedies for these, I find nothing equal to paraffin oil, a tablespoonful or so of which is sufficient to soak a quart of Peas, which, when so treated, are left unmolested, and are not in any way injured.

It may not be generally known that the young green tops of Peas make delicious soup, a luxury that may be enjoyed all through the winter. Of course it will not do to sow choice sorts for purposes of this kind, as that would make the soup come rather dear; nor is it necessary to do so, as any common cheap Pea will do equally well. The best way to treat them is to sow thickly in boxes or pans containing light soil; and if wanted quickly, to stand them where they will get a little heat, when they will soon be up ready for use, which will be directly they are about 1½ in. long. If allowed to get more forward than this they lose much of the delicate Pea flavour, and do not become incorporated with the soup so readily as when they are young and tender.

S. J.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Veitch's Self-protecting Autumn Broccoli.—I can fully endorse "W. G.'s" remarks (see p. 28) in reference to the usefulness of this Broccoli, but I am unable to cut from it at the time when he cuts. Would he kindly tell us at what time he sows, and if it requires anything more than an ordinary kitchen garden border?—J. W., *Leicester, Leicestershire*.

Bennett's Schoolmaster Potato.—In giving us this excellent variety of Potato, Mr. Bennett has done us good service. It is perhaps best described as an improved Regent.—R. GILBERT, *Burghley*.

THE FLOWER GARDEN.

PENTSTEMONS AND THEIR CULTURE.

PROBABLY no other hardy flower has been so much improved, and become so widely popular, during the last twelve or fifteen years, as the Pentstemon. It is now some years since it was taken in hand by cultivators with a view to its improvement, and by careful seeding from such attractive species as *P. gentianoides*, *P. Cobæa*, and others—but these two mainly—there has been obtained a race of very fine hybrids, the flowers of which are large in size, with long, trumpet-shaped tubes; bold and striking in appearance, varying much in colour, from pure white down to a dark, puce crimson; self-coloured, parti-coloured, flaked, and margined. The variety of colour is very great, and the new kinds produced each succeeding year show an increased size and a bolder character. Thirty-five years ago, *P. gentianoides* (*Hartwegi*) was much grown, and we used to esteem it a gem among hardy plants in the mixed border, and beds of this species used to make an attractive feature. Where it used to do so well was in a warm, sunny spot on the gravel in the south of England. The plants remained out-of-doors all the winter, and were simply lifted and re-planted early in spring. When it was desired to increase the stock, the plants were divided at the roots in the ordinary manner. Then we were unaware of the rich harvest in the form of hybrids which were being produced. Each succeeding generation is privileged to see something of higher value in the way of floral beauty than that which pre-

P. Jaffrayanus.

P. ovatus.

ceded it. The work of improving the Pentstemon has been carried on both by Continental and British cultivators, each realising important results.

Pentstemons succeed in any good soil; they are very accommodating, but in a good loam enriched with manure and leaf-soil they are certain to do well. They can be planted out singly or in groups in the mixed border or in beds, in which the various colours become charmingly blended. In some large gardens, where cut flowers are greatly in demand, I have seen beds of Pentstemons, Cloves, Asters, Stocks, and similar plants forming a kind of fringe to one of the walled-in divisions of a kitchen garden, or near the gardener's cottage, where they form attractive features. In an old-fashioned garden I once saw a huge circular bed having a centre of Hollyhocks, round which was a zone of Dahlias, and then a band of Pentstemons intermixed with *Gladiolus Brenchleyensis*, the circumference of the bed being filled up with ordinary bedding plants. In this arrangement the soft beauty of the Pentstemon was an attractive feature. The Pentstemon may also be used for ribbons, its continuous flowering character keeping it effective for a long time. Owing to the mild character of the autumn of 1876 Pentstemons were in full bloom quite up to Christmas.

The Pentstemon is increased both by means of cuttings and seeds. The former method must be resorted to in order to increase any particular variety. Cuttings should be taken in August or early in September, from the young growths thrown up round the main stem, and they should be put into a prepared sandy bed, on a shady border, under a hand-glass,

or in boxes or pots placed in a cold frame. They root readily, and those in boxes or pots might be wintered in this way, and not transplanted till spring. Those struck on the border should be lifted and potted, or planted out in a cold frame for the winter; or transplanted to the open ground in a well-prepared bed, and protected with a little litter or branches of evergreens during severe weather. Under general circumstances the young plants should not be planted out till the March or April following. When it is desired to increase the stock of any one or more varieties as rapidly as possible, the store pots of cuttings rooted in autumn should be taken into a gentle bottom-heat in spring, and induced to grow; and if the young growths be taken off as soon as they are 2 in. in length, and put in pans of sandy soil in the same temperature, they will quickly strike, and by May and June, if properly treated, will have grown into healthy plants. Seed only of the best varieties should be sown. The Pentstemon is a very free seeder, and there is no difficulty in obtaining some. In saving seed for sowing, only the very finest varieties should be selected for the purpose, and those showing novelty of character—for variation is always a most acceptable characteristic—and such flowers can scarcely fail to yield something well worthy of cultivation. The seed should be sown in February or early in March, in a gentle heat. It will quickly germinate, and when the plants are large enough to handle they should be pricked off into shallow boxes, and, after a time, hardened off in a cold frame. Here the plants can remain till the end of May or later, according to their size, and then be planted out in well-prepared beds. A generous soil will serve to bring out as fully as possible the quality of the seedling flowers. When they flower, which they will do by August and September, any varieties of extra good quality should be marked for propagation by cuttings or for seeding from, while the inferior ones will do for the mixed border. If the bed of seedlings be allowed to stand for another season (and it is always a good plan to do this), the seed-stalks should be cut away as soon as ripe, the bed cleaned, top-dressed with leaf-soil and short manure in spring, and it will yield a plentiful harvest of flowers the following summer.

The following are twenty-four beautiful varieties that may be obtained from any nurseryman making a speciality of the Pentstemon, viz.:—*Agnes Laing*, *Apollo*, *Apollon*, *Bridesmaid*, *Calliope*, *delicatissimus*, *Euterpe*, *Flora*, *Georges Sand*, *H. M. Stanley*, *Mons. Clément*, *Madame Louis Schmitzer*, *Monarch*, *Novelty*, *Pollie King*, *Giant*, *Iona*, *Stanstead Rival*, *W. E. Gumbleton*, *W. P. Laird*, *Secrétaire Cuzon*, *striatus*, *Volunteer*, and *Yeoman*. Of the species, *P. ovatus* and *P. Jaffrayanus* (of which the annexed are representations) well deserve cultivation. The flowers of *P. Jaffrayanus* are of a charming hue of blue, which is only to be found in a very few of the improved varieties. All the species are of an interesting character, and well repay cultivation. QUO.

Select Funkias.—Mr. Ellacombe (see p. 45) makes no mention of what I consider the noblest of all the Funkias, viz., *F. Sieboldi*, a fine species with creamy-lilac flowers and large cordate-pointed foliage, the latter quite of a tropical character, so much so, indeed, that it might well be used in sub-tropical gardening. I have seen it employed with good effect as an edging to a bed of *Yuccas*. However handsome *F. grandiflora* may be when well grown, it is not equal to *F. cordata*, a kind nearly as large as the former, but far handsomer in foliage, the beauty of which is enhanced by the leaves being thrown well out from the roots by means of very long petioles furnished with a narrow continuation of the leaf the whole length. Among variegated sorts perhaps *F. nodulata variegata* is the best—a perfect gem when grown in pots.—THOMAS WILLIAMS, *Ormskirk*.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Erica vagans alba.—In the churchyard at Eversley, Hants, and close to Canon Kingsley's grave, two large bushes of this Heath are now in full flower. Is not this unusually early?—W. H.

Early Primroses.—I have a quantity of Dean's varieties of Primrose in 48-sized pots sheltered in a cold Cherry-house, and they are just now (January 20) in full bloom. The diversity of their colours, varying as they do from white to a deep-set maroon, at this dull season renders them fit subjects for all kinds of decorative purposes; they are very effective, and should be grown extensively.—R. GILBERT, *Burghley*.

PLATE LVIII.

THE SPECIES OF FUCHSIA.

(WITH A COLOURED FIGURE OF *F. BOLIVIANA*).

By W. B. HEMSLEY.

THE genus *Fuchsia* has now been represented in our gardens nearly 100 years, and probably no genus of plants has enjoyed a greater share of general favour, or more richly rewarded the painstaking cultivator, and few things are more easily grown. Notwithstanding all these recommendations, and the fact that a few enthusiastic raisers still bring out annually a number of good, new varieties, there is no denying the fact that *Fuchsia*-growing has been for some years on the decline. This is not as it should be, and all the writing and talking in the world will not alter it; nor is it the object of this article to sing their praises. A brief sketch of each species, or merely the names of some few of the less ornamental ones, is all that space will permit. In a previous vol. of *THE GARDEN* some notes on the early hybrid and seminal varieties will be found; and this part of the subject the writer hopes to be able to work out more thoroughly. One thing appears certain, and that is, there has been much less intercrossing between distinct species to produce the cultivated varieties than one would at first suppose, or gather from the writings of some of the raisers of *Fuchsias*. As much information as could be compressed in the space is given under each species below, and, therefore, this introductory part shall be as brief as possible. The hardy varieties of No. 32 deserve the attention of every gardener. A selection of species, including all the main types of the genus, should embrace *F. arborescens*, *coccinea*, *corymbiflora*, *fulgens*, *macrantha*, *magellanica*, *microphylla*, *procumbens*, *simplicicaulis*, *spectabilis*, *splendens*, and *venusta*. In a larger collection the following should find a place:—*F. alpestris*, *bacillaris*, *boliviana*, *caracasensis*, *cordifolia*, *excorticata*, *integrifolia*, *lycioides*, *sessilifolia*, *serratifolia*, and *thymifolia*. Among handsome species not yet introduced, *F. ampliata*, *corollata*, *insignis*, *longiflora*, *petiolaris*, and *salicifolia* may be mentioned. The arrangement of the species adopted is not based altogether upon scientific grounds, but it will perhaps be none the less useful for horticultural purposes.

American Species having Petals.

I.—Species inhabiting the Andes of Bolivia, Peru, Ecuador, New Granada, &c. With few exceptions, noted in each case, the calyx-tube is longer (often several times longer) than the sepals, and the stamens rarely project beyond the petals when the latter are erect. The latter are usually smaller than the sepals, but sometimes larger, as in *F. corollata* and a few others.

1. **Roezl's Fuchsia** (*F. boliviana*).—This handsome *Fuchsia* is of compact habit, dwarf growth, and these qualities, combined with the brilliant colour of its flowers, require no recommendation. It belongs to the *corymbiflora* group, but in the absence of specimens, it is impossible to say anything more definite of its affinities. Mr. Roezl discovered it in Bolivia in 1873, growing at an elevation of, it is stated, of about 6000 metres (19,500 ft.), but this is doubtless a slip of the pen or a printer's error. It was exhibited at one of the meetings of the Horticultural Society a few months ago, and though not so showy as some of its congeners, it has a promising appearance.

2. **Cluster-flowered Fuchsia** (*F. corymbiflora*, Bot. Mag., t. 4000).—A tall species, with large leaves and terminal clusters of large, uniform, deep red flowers, something in the way of *F. simplicicaulis*, but the leaves and other young parts are very hairy, and the inflorescence does not lengthen out so much; neither are the leaves usually whorled. In cultivated specimens the lanceolate, long-stalked leaves attain 1 ft. or more in length, and the flowers are from 2½ in. to 3 in. long; the tube slender, and gradually tapering throughout; sepals and petals about ½ in. in length, the former reflexed close on the tube. The late Mr. Standish introduced this fine Peruvian species nearly forty years ago, but it seems not to have become widely dispersed in gardens. In its native country it forms long, flexible branches, which are supported by the surrounding trees and shrubs. In Paxton's "Magazine of Botany," 1849, p. 219, a *F. corymbiflora* alba is described. It was raised by Mr. Salter, of Hammersmith and Versailles. The tubes of the flowers are described as being of a carmineous whiteness at first, but eventually pure white, and the corolla, which the reflexed sepals fully reveal, of a brilliant crimson. A figure of this variety in the "Flore des Serres," t. 517, represents

the tube and sepals as pure white, and the petals as deep red suffused with purple. *F. dependens*, Hooker, "Icones," i., t. 65, is probably only a smaller-flowered, less luxuriant state of the same species.

3. **Single-stemmed Fuchsia** (*F. simplicicaulis*, Bot. Mag., t. 5096).—This is remarkable among the tall-growing *Fuchsias*, with large whorled leaves for its long, slightly-branched stems, terminating in long pendulous racemes of flowers, interspersed with large leafy bracts, gradually smaller towards the end of the inflorescence. The flowers are of an almost uniform crimson, 2½ in. to 3 in. long, the relatively short sepals and petals nearly equal in length, and slightly spreading, and overtopping the yellow anthers. A native of Peru, introduced by Messrs. Veitch, through their collector, W. Lobb, about twenty years ago. A magnificent ornament in a large conservatory.

4. **Crowded-leaved Fuchsia** (*F. confertifolia*, *Piedding and Gardner's "Sertum Plantarum,"* t. 28).—A dwarf, much-branched shrub, with slender woody branches, clothed with rusty bristly hairs. Leaves less than 1 in. long, oval, acute, almost stalkless, crowded especially at the end of the branches; flowers borne in small clusters at the end of the branches, slender, 1½ in. to 2 in. long; sepals and petals equal, the latter of a darker red; stamens included. Distinct from all the other long-flowered section in its small crowded leaves. A native of Peru, not yet introduced in a living state.

5. **Hartweg's Fuchsia** (*F. Hartwegi*, *Bth.*).—A distinct and pretty *Fuchsia* with oblong, lanceolate leaves, hairy beneath, from 2 in. to 1 in. long, opposite or whorled, and borne on relatively slender stalks about ½ in. long. Flowers very numerous, in terminal leafy panicles, very slender, about 1½ in. long; sepals very narrow, and spreading about ½ in. long; petals shorter, of a purplish-red; stamens scarcely exerted. This must be a very ornamental species, but, with the exception of the petals the colour has left the dried specimens, and there is no indication of it on Hartweg's label. Common in hedges near Huambra and elsewhere.

6. **Hairy-flowered Fuchsia** (*F. hirtella*, *H. B. K.*).—Very near *F. Hartwegi*, having, however, broader leaves and larger flowers, which are more conspicuously hairy than in any of the allied species, and in which the petals are as long as the sepals. A native of Colombia, not in cultivation.

7. **Wood Fuchsia** (*F. sylvatica*, *Bth.*).—A pretty species of the set having terminal leafy racemes of small flowers, in this species scarcely exceeding 1 in. in length. The leaves are more or less hairy and membranous. In general characteristics it approaches *F. hirtella* and *F. Hartwegi*, described more in detail, but it is less ornamental. Discovered by Hartweg in woods on the western declivity of Pichincha.

8. **Sessile-leaved Fuchsia** (*F. sessilifolia*, Bot. Mag., t. 5907).—A rather attractive species, although the flowers are small. Of rambling habit, with angular bright red stems, stalkless, glabrous, toothed leaves, 4 to 9 in. long, and arranged in whorls of four. Flowers very numerous, in leafy bracteate panicles; tube rose, passing into yellowish green at the base and in the sepals; petals deep red. Raised by Mr. Anderson-Henry from seeds received from Professor Jameson, of Quito, in 1865.

9. **Shaggy Fuchsia** (*F. ovalis*, *Rui. and Pavon*, Fl. Peruv., t. 324, A.; *F. pilosa*, *Piedding and Gardner's Sertum Pl.*, t. 27).—The plants figured in the two works quoted differ only in the shape of their leaves; and from the additional evidence of dried specimens, I have no doubt they are simply varieties of one species. It is true the figure in "Flora Peruviana" does not show the bristle-pointed (mucronate) sepals, but the description agrees well enough—a shaggy, hairy plant, even to the flowers, with oval or lanceolate-stalked leaves 3 in. to 5 in. long, and terminal leafy racemes of small crimson flowers. A Peruvian species not in European gardens, and of little ornamental merit.

10. **Shade-loving Fuchsia** (*F. umbrosa*, *Benth.*).—One of Hartweg's discoveries near Quito, possessing no particularly ornamental features. It belongs to the group with relatively short sepals and included stamens.

11. **Hoary Fuchsia** (*F. canescens*, *Bth.*).—A shrubby species 6 ft. to 10 ft. high, with the small oval or oblong leaves arranged in whorls of three or four; flowers on short stalks in the axils of the upper leaves 1½ in. to 2 in. long; petals broad, shorter than the ½-in. long, obtuse sepals, stamens included. Colour of the flowers not given. A native of Colombia and Peru. Not in cultivation.

12. **Saw-leaved Fuchsia** (*F. serratifolia*, Bot. Mag., t. 4174).—A tall-growing kind, the young shoots deep red, and the usually prominently toothed leaves, which are from 1 in. to 6 in. in length, usually in whorls of three or four, or sometimes opposite. Flowers

large, 2 in. to 3 in. long, singly on long stalks from the axils of the leaves, and very beautifully coloured. The broad tube, which is somewhat inflated at the base, is of a rich crimson, shading off gradually into rose-pink upwards and a yellowish green in the tips of the sepals, which overtop the broad, rounded petals. The latter are crimson with a white base; stamens protruding slightly beyond the petals. This is certainly one of the handsomest Fuchsias for greenhouse culture hitherto introduced. Mr. William Lobb was the first to send home living plants, which he collected in the mountains of Peru, and Messrs. Veitch were awarded a gilt medal for it by the Horticultural Society in 1845.

13. Lovely Fuchsia (*F. venusta*, *H.B.K.*, "Fl. des Serres," t. 538).—A tall-growing species, with the lanceolate nearly or quite entire, leaves usually in threes, and the orange-scarlet flowers pendent from the axils of the leaves on slender stalks 2 in. or more in length. Leaves thick and shining, resembling those of an *Allamanda*. Flowers about 3 in. in length, the wavy-margined petals longer than the very acute green-tipped sepals. Stamens scarcely projecting. This handsome plant is a native of New Granada, and was introduced into cultivation by Mr. Linden in 1847. It grows at an elevation of some 8000 ft., and consequently requires only a greenhouse temperature. In the herbarium at Kew there are several specimens named *F. cinnabarina*, a name of which I have found no publication. Two apparently distinct species are so named at Kew, and therefore I have no clue to the real thing beyond the fact that it must be closely allied to *F. venusta*. Most likely *F. cinnabarina* is a plant discovered by Mr. Linden in New Granada, or it was sent out by him as a new plant.

14. Warty-branched Fuchsia (*F. verrucosa*, *Hartweg*).—A small-flowered species, the young branches of which are usually more or less covered with wart-like excrescences. Leaves opposite, on quite short stalks, about 5 in. long, and very prominently veined on the under surface. Flowers less than 1 in. long, and solitary in the axils of the upper leaves. Native of New Granada, where Hartweg first detected it.

15. Rough-leaved Fuchsia (*F. scabriuscula*, *Benth.*).—A small-flowered species, native of Peru, of botanical interest only. It is remarkable for its very rough, wrinkled leaves.

16. Ayavaca Fuchsia (*F. ayavacensis*, *H.B.K.*).—An erect, shrubby species with lanceolate, hairy leaves, silvery beneath, 3 in. to 4 in., arranged in whorls of three. Flower-tube about 2 in. long, sepals and petals $\frac{1}{2}$ in., enclosing the stamens. I have only seen dried specimens, but the hairy flowers are described as becoming purple.

17. Club-shaped Fuchsia (*F. ampliata*, *Bth.*).—A branching, shrubby species, with hairy, opposite, or ternate lanceolate leaves, 2 in. to 4 in. in length, distantly and coarsely toothed, and very showy flowers with remarkably broad, rounded petals, and reflexed sepals. The tube is quite slender at the base for about $\frac{1}{2}$ in. and then abruptly widened. Judging from dried specimens only, this must be an exceedingly ornamental species. It is described as a shrub (apparently of compact growth) from 3 ft. to 10 ft. high, with a red calyx and scarlet corolla. It has a wide range in the mountains of Peru, growing at great altitudes up to 11,000 ft. Collectors should look after this.

18. Black-petaled Fuchsia (*F. caracasensis*, *Fielding and Gardner*, *Sertum Pl.*, t. 29; *F. nigricans*, "Fl. des Serres," t. 481).—A curious, though not ornamental, species, remarkable for its very dark purple, almost black, petals. It is of a somewhat loose, straggling habit, with wrinkled, hairy leaves 2 in. to 4 in. long, and arranged in threes. Flowers on short stalks in the axils of the upper leaves, about 1 in. long; sepals less than $\frac{1}{2}$ in. long, petals a little longer, stamens included. A native of New Granada and Peru; originally discovered by Moritz, and subsequently collected and introduced by Linden; but his name, although more appropriate, must give way to the earlier one of *caracasensis*.

19. Cinnabar-red Fuchsia (*F. petiolaris*, *H.B.K.*; *F. miniata*, *Planchon and Linden*, "Fl. des Serres," t. 754).—The plate quoted represents a showy plant with stout deep red shoots, smooth, obscurely-toothed, whorled leaves in fours, about 4 in. long, on deep red stalks, and pendent cinnabar-red flowers about 3 in. long. The sepals are tipped with green and slightly spreading, and the projecting stigma is spherical. I find no essential difference between Linden's plant and Humboldt's *petiolaris*, and the same author's *quindiensis* is probably a slightly hairy form of the same species. It is a profuse-flowering species from the Peruvian Andes.

20. Long-flowered Fuchsia (*F. longiflora*, *Benth.*).—A shrub, 5 ft. high, from the western declivity of the Andes of Quito, with thin, rough leaves, 4 in. to 6 in. long and axillary, solitary flowers, remarkable for the long, slender, slightly curved tube, and broad-

spreading petals; the tube is 3 in. or more in length, and the fully expanded flower about 2 in. in diameter; stamens not exceeding the petals in length. Discovered by Hartweg, who says it was very rare, and it has not been found by subsequent collectors. Judging from dried specimens alone, it appears to be a very ornamental plant; but, of course, one can say nothing as to its habit of growth. *F. macrostigma* of the same author differs only in its smaller flowers.

21. Purple-leaved Fuchsia (*F. spectabilis*, *Bot. Mag.*, t. 4375).—A noble species, with thick, succulent, dark purple shoots, broad leaves, 6 in. to 8 in. long, purple beneath, and dark green above, and half erect, finally pendulous flowers on short, stout stalks in the axils of the leaves. The flowers are nearly 3 in. long, and of a deep scarlet, slightly suffused with purple, stamens included; certainly one of the handsomest of the genus. It was collected by Mr. Lobb for Messrs. Veitch, who first exhibited it in 1848. He found it in shady woods in the Andes of Cuenca, growing about 2 ft. to 4 ft. high, and speaks of it as the loveliest of the lovely.

22. Loxa Fuchsia (*F. loxensis*, *Humboldt, Bonpland, and Kunth*, *Nova Gen. et Sp.*, vol. vi., t. 536).—A very dense, leafy shrub, nearly or quite glabrous in all its parts, with leaves 2 in. to 3 in. long. The flowers scarcely exceed 1 in., and have very short, erect sepals and petals; tube gradually wider upwards. This Peruvian species, from the neighbourhood of Loxa, was in cultivation at Kew in 1862. The leaves of the cultivated plant were purplish beneath, and the flowers deep red.

23. Large-petaled Fuchsia (*F. corollata*, *Bth.*).—One of the finest species of those not in cultivation—at least this is not in cultivation to my knowledge. It is a shrub 6 ft. to 8 ft. high, with coriaceous, ovate, or oblong leaves, remotely toothed and often deeply wrinkled. Flowers 2 in. to 2½ in. long, tube slender at the base, enlarged upwards; petals broad and nearly $\frac{3}{4}$ in. long, considerably overlapping the sepals, and of a very pretty, red colour. One of Hartweg's discoveries in the mountains of Colombia at an elevation of 10,000 ft. Collectors should look after this: the exact localities given are woods at Parace and on the ascent from Paramo to Guanacas, near Popayan. *F. macropetala* of Presl is unknown to me at present; it may belong here.

24. Curved-flowered Fuchsia (*F. curviflora*, *Bth.*).—Another of Hartweg's discoveries in Colombia in the Andes of Bogota at an elevation of 10,000 ft. A shrubby plant, 4 ft. to 5 ft. high, with small (about 1½ in. to 2 in. long) whorled leaves and solitary axillary flowers on short stalks. The slender flower-tube is more or less curved, and the white sepals contrast well with the deep red petals.

25. Toothed-leaved Fuchsia (*F. denticulata*, *Ruiz and Pavon*, *Fl. Peruv.*, t. 425).—According to the figure, this has coarsely toothed, strongly veined, stalked leaves, about 3 in. long, and flowers smaller, but otherwise not unlike those of *corollata* and *ampliata*. It is described as a very handsome plant, and bears a name signifying the same thing in the Indian vernacular.

26. Cross-branched Fuchsia (*F. decussata*, *Ruiz and Pavon*, *Fl. Peruv.*, t. 323, B., not of *Bot. Mag.*, t. 2507).—I know this only from the figure. It is described as a pretty, slender shrub, about 3 ft. high, with small leaves in threes, and scarlet and crimson flowers less than 1 in. long, and borne on slender stalks nearly twice their length; stamens projecting beyond the petals. Stated to grow abundantly at Muna. This appears to be allied to *F. magellanica* and the Brazilian species.

27. Original Fuchsia (*F. triphylla*, *Burmah's Edition of "Plumier's Plates of American Plants,"* t. 133; and perhaps *F. racemosa*, *Linnaeus*, "Encyclopædia," t. 282, fig. 1).—It has already been mentioned under *F. magellanica* where the first figure of a Fuchsia appeared, but this *F. triphylla* is the first plant figured under the name of Fuchsia. The figure, however, is so rude, that nobody, I believe, has been able to identify it with any living or dried plant. Possibly it is not a Fuchsia at all in the sense of the present application of the name, for it is represented as having only four stamens.

2.—Species inhabiting Brazil, characterized by having sepals as long or longer than the tube, and stamens projecting considerably beyond the petals.

28. Aiton's Fuchsia (*F. coccinea*, *Aiton*, *Bot. Mag.*, t. 5740, not *Bot. Mag.*, 97; *F. montana*, *Cambesede St. Hilaire*, *Fl. Bras.*, t. 135; *F. elegans*, *Salisb.* *Stirp. Rar.*, t. 7).—About 1788 both this and one of the varieties of *F. magellanica* were introduced; this soon became rare, and the other usurped its name, and is still widely, in fact almost universally, known to gardeners as *F. coccinea*. A few years ago Dr. Hooker found the true *F. coccinea* growing in the Botanic Garden at Oxford, and having identified it with authentic

specimens, he cleared up the synonymy of the two species. In a previous article in THE GARDEN I pretty fully explained all there is of interest to horticulturists concerning this species, consequently I may dismiss it here in a few words. I have seen no wild specimen from Brazil of *F. coccinea*, but I think there can be no doubt that the *F. montana* quoted above, of which, however, I have seen only the figure, is the same thing. *F. coccinea* is of graceful habit, and has slender, rosy-red flowers on long stalks. The leaves have a heart-shaped base, and are borne on short bristly-hairy stalks, usually three at each joint. Altogether it is so distinct from any of the varieties of *F. magellanica*, that it may be distinguished at a glance.

29. Cambessedé's Fuchsia (*F. pubescens*, *St. Hilaire*, Fl. Bras., vol. ii., t. 134) — Judging from the plate referred to, this is very near *F. coccinea*, differing in being of a more compact habit, in having smaller flowers and an almost spherical, not cylindrical, fruit.

30. Gardner's Fuchsia (*F. alpestris*, Bot. Mag., t. 3999). — A rampant-growing species with large leaves, 4 in. to 6 in. long, as well as the young stems, densely pubescent; the relatively small flowers usually borne singly in the axils of the leaves. It is of rambling habit, inhabiting moist bushy places on the Oregon Mountains at an elevation of about 5000 ft. Although introduced in 1842, it has not become widely dispersed in gardens, and as it is inferior to many others as an ornamental plant it will most likely continue rare. For a large greenhouse or conservatory it may be recommended, because it will quickly cover a large space with its ample foliage, and climb to a height of 20 ft. or 30 ft.

31. Aerial-rooting Fuchsia (*F. integrifolia*, *Camb.*; syns. — *F. alpinis*, *Camb.*; *F. pyriformis*, *Presl*; and *F. radicans*, Bot. Reg., 1844, t. 66). — The last is the name by which this plant is known in gardens. It is similar in habit and foliage to the last, freely throwing out clusters of roots from its branches in its native haunts. In this, the leaves are almost glabrous and the flowers are more richly coloured, the sepals being of a bright scarlet, and the relatively small petals violet-purple. For the same purposes as the last, this is, perhaps, to be preferred.

3.—Species inhabiting Chili and Patagonia.—These belong to two groups. *Fuchsia magellanica* has the long stamens of the Brazilian species, and the other two have very small flowers with short stamens approaching the small-flowered ones from Mexico.

32. Thilco Fuchsia (*F. magellanica*, *Lamarck*, *Eucy.*, t. 282; syn. *F. macrostema*, *Ruiz and Pavon*, Fl. Peruv., t. 321, fig. B.; *F. coccinea*, Bot. Mag., t. 97, not of Aiton). Under the Chilean native name of Thilco, Feuillée, in his Journal des Obs. Bot., &c., vol. iii., p. 61, t. 47 (1725), published the first description and figure of a Fuchsia. Although he represents his plant as having nine or ten stamens, there is no doubt that it is a true Fuchsia, and from the locality where it was gathered, 54° south latitude, it is most likely the present one. This view is strengthened by the fact that Ruiz and Pavon in the work quoted above give the same native name for their plant, which is also Chilean. It is a singular thing that this and the true *F. coccinea* should have so soon got confused. Aiton described his *F. coccinea* in 1789 ("Hortus Kewensis," vol. ii., p. 8), and it is stated there that it was sent to Kew from Chili by Captain Firth in 1788. In 1791 Salisbury ("Icones Stirpium Rariorum") figured the same thing under the name of *F. elegans*, as having been sent from Brazil by Vandelli about the year 1787. There are authentic specimens in existence which prove that the plant commonly known in gardens, and figured in several serials as *F. coccinea*, has nothing to do with the true plant. Aiton's plant is doubtless Brazilian, and there are very few species in Brazil. On the other hand there is no doubt that the plant figured in the Bot. Mag., t. 97 (1789), is the true *F. magellanica*, a much hardier Chilean species; indeed, all the really hardy varieties seem to belong to this one species. In a wild state, as well as under cultivation, it presents a wide range of variation in the size of its leaves and flowers, and in other particulars. I propose briefly describing a few of the more distinct, which have been figured in one or other of the periodicals. The plant represented in the Bot. Mag., t. 97, is of robust habit, has deep red or almost scarlet veins in the leaves, and rather large flowers, with broad scarlet sepals and purple petals; with the exception that the petals only slightly spread, this is equal to the best of the hardy varieties. *F. conica*, *Lindley*, Bot. Reg., t. 1062, is a very leafy variety, of compact habit, but not a very free bloomer. The calyx is scarlet, with a conical tube, about as long as the arching sepals, and the dark purple petals are nearly as long as the sepals. This was raised from seeds brought from Chili by Mr. Place, who presented them to the Horticultural Society in 1824; it may easily be distinguished by the very broad base of the calyx-tube, tapering upwards. *F. globosa*, *Lindley*, Bot.

Reg., t. 1556; is a familiar old variety, the flowers of which are quite globose in bud, a shape they retain for some time after they begin to expand on account of the petals continuing to adhere to the tips. The tube of the calyx is very short and almost spherical. This is an extremely profuse bloomer and the flowers are richly coloured. According to Mr. D. Don, it was raised by a Mr. Bunny from seed of *F. conica*. This still remains one of the best of the hardy Fuchsias. *F. gracilis*, *Lindley*, Bot. Reg., t. 817, syn. *F. decussata*, *Graham*, Bot. Mag., t. 2507. — A very distinct form from either of the foregoing, being of slender habit, and having larger and longer flowers borne on remarkably long, slender stalks. The young shoots are of a purplish-red, and the calyx is of a brighter scarlet, and the corolla has a greater infusion of red than either of the varieties described above. It is stated that this Fuchsia was raised from Mexican seed in the Botanic Garden at Edinburgh in 1822; but it does not agree with any of the Mexican forms, and it is equally as hardy as any of the Magellanic group. A writer in London's "Gardeners' Magazine," in 1832, states:—"I have in my garden (at Whitby) at the present time in the open ground a plant of *Fuchsia gracilis* nearly 7 ft. high, and from 12 ft. to 15 ft. in circumference, and loaded with flowers. It has been planted out three years, and last winter it was not cut down at all. My garden is in an open situation, three quarters of a mile from the sea, and about 120 ft. above its level." Pity it is that these beautiful plants are so little grown now. In the Bot. Reg., t. 1052, there is a figure of a Fuchsia called *F. gracilis*, var. *multiflora*, said to have been raised from Chilean seeds presented to the Horticultural Society by Mr. Place in 1824. It is a very free-flowering kind, with shorter, darker crimson flowers than *gracilis*. *F. tenella* is a seedling variety of *F. gracilis*. One might go on enumerating the varieties of this group, but it would be of little practical use and occupy too much space. However, being the only hardy set, it may be worth while mentioning one or two others. *F. discolor*, *Lindley*, Bot. Reg., t. 1805, is a dwarf variety, producing a profusion of small flowers with spreading sepals. It was better known in gardens as *F. Loweii*, and was raised by Mr. Lowe from seeds procured by Mr. Anderson, who accompanied Captain King. It was found at Port Famine, in the Straits of Magellan, the most southerly habitat of any of the Fuchsias. It is stated to be the hardiest of all, not being injured even by the winters of Scotland; but this probably has reference to the milder parts only; at all events, there can be no doubt of its hardness in any part if treated as an herbaceous plant. Whether this particular variety is still to be found in gardens I cannot say. A dwarf, slender variety is cultivated at Kew under the name of *pumila*: this is of almost trailing habit. *F. racemosa* of *Lamarck's* "Encyclopædia," t. 282, should probably be referred here, and perhaps also *F. multiflora* of Willdenow. Finally, I have to mention *F. recurvata*, Bot. Mag., t. 3521, a large-leaved, large-flowered variety remarkable for the length of the flower-stalks and the recurved sepals. I had almost forgotten to mention that *F. chonotica* and *F. araucana*, lately published by Philippi, can only be regarded as slight varieties of *magellanica*; and among the best varieties now commonly met with I ought to mention *corallina* and *Riccartoni*. *F. virgata* of Sweet should also be referred here.

33. Box Thorn-like Fuchsia (*F. lycioides*, *Andrews'* "Botanists' Repository," t. 120, syn. *F. rosea*, *Ruiz and Pavon*). — This bears a strong resemblance to *Lycium afrum* both in foliage and its small scattered flowers. As in *F. spinosa*, the woody leaf-stalks persist, and the flowers, judging from the plate quoted above and Bot. Mag., t. 1024, vary considerably in size and colour. Possibly *F. spinosa* is only a form of this growing in arid places; but none of the forms are remarkable for beauty. *F. lycioides* is interesting as being one of the first species cultivated in Europe, and having been introduced by Mr. Archibald Menzies from Chili before 1796. It first flowered in this country in the King's Garden at Kew some time during the year named. *F. parvidora*, *Lindley*, Bot. Reg., t. 1048, seems to be a small-flowered variety with long-stalked leaves. It is stated under the plate quoted that it is a native of Mexico; but this may be wrong. In fact, I have seen nothing at all like it among the numerous Mexican specimens that have passed through my hands. Seeds were presented to the Horticultural Society in 1824 by the Right Hon. George Canning, and it flowered in the Chiswick Garden for the first time in an open border in 1826.

34. Spiny Fuchsia (*F. spinosa*, *Presl*, "Reliquie Hænkearne," t. 51). — In habit, foliage, and flowers, this comes very near *F. lycioides*, but the petals are much smaller than those of the latter. It has thick, warty, often spiny branches, very small, appressed leaves from $\frac{1}{2}$ in. to $\frac{3}{4}$ in. long, on short, thick, hardened stalks, which persist after the blade has fallen away, and red flowers about $\frac{1}{2}$ in. long. The stamens are no longer than the minute petals, but the style projects considerably in the specimens I have seen. A native of Chili presenting no specially ornamental features.

4.—Species inhabiting Mexico and Guatemala. These include the very small-flowered Fuchsias, in which the stamens are included of which *F. microphylla* is the type; a small group, of which *F. splendens* is typical; and the singular *F. arborescens*.

35. Miniature Fuchsia (*F. microphylla*, Bot. Reg., 1269).—Although this will in time grow to a height of several feet, if supported, it is, as usually cultivated, a perfect miniature Fuchsia, forming bushy plants 9 in. to 18 in. high, covered with a profusion of small, deep red flowers. It is, perhaps, the most familiar of the group to which it belongs, and therefore a detailed description would be unnecessary, were it not that its less ornamental allies often get into gardens under the same name. This possesses certain advantages which entitle it to precedence on all occasions. In the first place it is evergreen, and the smooth leaves usually less than $\frac{1}{2}$ in. long, and borne on very short stalks, are elegantly toothed on the margin, and closely arranged on the branches. Farther, the flowers, though smaller, are more abundant and of a richer colour. *F. thymifolia* frequently represents this species, and although a pretty plant, it is far inferior to the present. It has soft, minutely hairy leaves, quite entire on the margin, and borne upon relatively long stalks. *F. microphylla* was first discovered by Humboldt and Bonpland on the volcanic mountain Jorullo, Mexico, and later travellers have collected it in widely distant mountain regions of Mexico and Guatemala. On the peak of Orizaba it ascends to an altitude of 10,000 ft. Introduced into our gardens about the year 1838, and figured in most of the garden periodicals of that date. There are several garden varieties, as major, reflexa, and Millezii. This is sometimes grown under the name of pendula. *F. Notarisi*, *Lehmann*, of which I have seen no specimens, is described as differing widely in the shape of its smaller flowers, the sepals and petals spreading at right angles to the tube. *F. gracilis* of Mocino and Sessé is the same as *microphylla*.

36. Thyme-leaved Fuchsia (*F. thymifolia*, Bot. Reg., t. 1281).—This was also discovered by Humboldt and Bonpland, and was introduced about the same date as the last. Besides the foliage and other particulars mentioned under the last, this species differs from its closer allies in having a fannel-shaped (not cylindrical) tube and larger-spreading sepals and petals; but I am not quite sure how far this is a reliable character, for the sexes are more or less separated here, and perhaps some of the individuals may be wholly male or female, and the flowers of the two sexes different in size and shape. Thus *F. parviflora*, syn. *F. enclandra*, has quite similar foliage with much smaller flowers usually, though they appear to vary very much in this respect. But this group requires carefully studying before one can attempt to define the species. In the true *parviflora* the flowers appear to be always cylindrical as in *F. microphylla*.

37. Four-fingered Fuchsia (*F. tetradactyla*, *Lindley*).—The name has reference to the large star-shaped stigma divided into four fleshy finger-like rays which project beyond the petals. It is nearly allied to *thymifolia* and *cylindracea*, but less ornamental, the deep rose-coloured flowers being only about $\frac{1}{2}$ in. long; Dr. Lindley describes it as having a tuberous root-stock: a native of Guatemala, introduced in 1816 by G. U. Skinner. *F. acynifolia* of Scheidweiler, stated to be a Mexican species of this group, is unknown to me, and described in a book which I have not been able to consult.

38. Barker's Fuchsia (*F. cylindracea*, *Lindley*, Bot. Reg., 1838, t. 66).—A pretty species, resembling a small-flowered Cuphea. It belongs to a small group of Mexican and Central American species, which includes the two next, characterized by having small cylindrical flowers, with very short tooth-like sepals, very small petals, and stamens included in the tube. Another peculiarity of this particular group is that the sexes are separated as in some of the New Zealand species. Dr. Lindley states that some plants are wholly male and others female, but rudimentary stamens are present in the female flowers, and a short style in the male flowers, with foliage very much like *F. thymifolia*, though rather larger. This has in the male plant dark red flowers slightly tipped with yellowish-green, about $\frac{1}{2}$ in. long, and borne on slender stalks 1 in. to 2 in. in length. The female flowers are little more than half as large. This attractive Fuchsia was first raised in the Horticultural Society's garden from Mexican seeds presented by G. Barker, of Birmingham.

39. Rod-branched Fuchsia (*F. bacillaris*, *Lindley*, Bot. Reg. t. 1480).—A very pretty and distinct species of the small-flowered Mexican group, with long, slender, smooth branches, perfectly glabrous, ovate or lanceolate leaves, and small rosy-red flowers, remarkable for their relatively large-spreading petals and small narrow sepals. The leaves are from 1 in. to 2 in. long, and the slenderly-stalked flowers are about $\frac{1}{2}$ in. in diameter. A native of Mexico, introduced in 1829, and first flowered in the garden of the Horticultural Society.

40. The Glowing Fuchsia (*F. fulgens*, Bot. Mag., t. 3801).—Of the handsome group to which this species belongs this is the only one that is now in general cultivation, and it fully merits this exceptional favour. It is not so brilliantly coloured as some of its congeners, but it is a free bloomer and flourishes in the most unskilful hands. The foliage of this, though it has been called coarse, is the boldest of any species in the genus, and this, coupled with the terminal, pendent racemes of very long, slender, vermilion-red flowers, tipped with green, affords characters by which it may be easily distinguished from its allies. Treated as an herbaceous plant it annually throws up from its tuberous root-stalk stout, succulent shoots, clothed with large, soft, heart-shaped leaves, and terminating in racemes of flowers which continue elongating and producing new flowers until late in the autumn. There is no doubt that this species played an important part in the early hybrid Fuchsias. It was introduced about 1836, and it was not until after that date that any real novelties in the so-called hybrids appear: but I have not sufficient space to enter into that part of the subject here. *F. fulgens* is a native of the mountains of Mexico, and was introduced by Hartweg.

41. Heart-leaved Fuchsia (*F. cordifolia*, Bot. Reg. 1841, t. 70).—Very near *F. splendens*, but having much larger, more conspicuously hairy flowers of a darker crimson on the tube, and with less yellow on the sepals; but it varies in the size and brilliancy of its flowers according to its cultivation. In the Bot. Reg., quoted above, they are represented as 2 in. long, and in Paxton's "Magazine of Botany," vol. ix., p. 99, quite 2 $\frac{1}{2}$ in. long. Another character by which it may be recognised is furnished by the scarcely projecting stamens. This also was introduced by Hartweg, who collected it in Guatemala, at an elevation of 10,000 ft., about 1840. In the collection of drawings at Kew there is an unpublished coloured figure of a Fuchsia, named *F. Kermesina*; it is very near *F. cordifolia*, but the leaves are wedge-shaped at the base, and the flower-stalks are much shorter.

42. Hartweg's Fuchsia (*F. splendens*, Bot. Mag., t. 4082).—This very striking plant was raised in the Horticultural Society's garden from seeds collected by Hartweg on Mount Tototepaque, in Mexico, at an elevation of 10,000 ft. It is of shrubby habit, and has cordate or ovate softly hairy leaves on long stalks, and axillary flowers on long slender stalks. The calyx-tube is broad and short, and of a vivid scarlet, while the short and almost erect sepals and petals are yellow and green; and the yellow stamens project $\frac{1}{2}$ in. or more beyond the mouth of the tube. Under proper treatment this flowers freely, but it should be allowed little pot-room, and it requires a cool climate.

43. Laurel-leaved Fuchsia (*F. arborescens*, Bot. Mag., t. 2620).—This is so different in appearance from all other Fuchsias, that nobody would suspect its affinity before having examined the structure of its flowers. It reminds one more of a small-flowered *Ixora* or some allied plant than a Fuchsia; it is described as a fine tree, and is a native of the lofty mountains of Mexico and Guatemala. The wild specimens exhibit a considerable variety in the size, degree of hairiness, and margin of the leaves, and under cultivation the leaves are as large, though not so thick, as those of the common Laurel, being sometimes as much as 8 in. long. In the cultivated plants they are nearly or quite smooth, with scarcely any trace of teeth on the margin. The flowers are almost as small as those of *F. microphylla*, but they are slenderer, and the sepals and petals, which are nearly equal in size and uniformly spreading, are relatively long and narrow; what they lack in size, however, is made up in number, and they are borne in erect, much-branched, terminal panicles, the individual flowers also being erect. It was introduced into this country by several different people about 1823, and appears to have first flowered at Bury Hill, then the residence of Robert Barclay, in 1825. Though it will not bear our severest winters, the following extract from London's "Gardeners' Magazine" furnishes evidence of its hardiness and beauty in one of the milder counties of England:—"*Fuchsia arborescens*, a native of Mexico, has attracted the observation of many scientific men here. It is 22 ft. high, with a head 40 ft. in circumference, the trunk at the surface of the soil 16 in. in girth and 3 in. from the ground; where it begins to branch off, 14 in. It had fifty trusses of flowers on it last August, and continued flowering in succession until the end of December. The trusses were 14 in. in diameter and 1 ft. long. I bought this plant of Mr. Veitch, of Killerton Nursery, six years ago, and I grow it in a mixture of loam and peat."—JAMES HARRISON, *Bridehead House, Somersetshire*, Feb. 19, 1836. If this fine Fuchsia would flourish and make so fine a display out-of-doors forty years ago it must be worthy of the consideration of the present generation of gardeners. In the original variety the flowers are of a rosy-pink, the petals slightly tinged with purple. But a few years ago some Continental nurseryman sent out a distinct variety under the name of *F. syringeflora*, a not inapprop-

private name, judging from a coloured plate in the "Revue Horticole," 1873, p. 311. The flowers are of a reddish-lilac hue and in very dense clusters, not unlike those of some of the varieties of Lilac. *F. aucana* is synonymous with *F. arborescens*.

44. **Skinner's Fuchsia** (*F. paniculata*, *Lindley*, *Gard. Chron.*, 1856, p. 301).—This I have not seen, but from Schiede's specimen referred to by Dr. Lindley, I should regard it as nothing more than a variety of *F. arborescens*, though quite distinct from a horticultural point of view. It is said to differ from *arborescens* in its pyramidal inflorescence, much smaller flowers, and small, obovate, or ovate-lanceolate leaves. The flowers are wine-red, and in the mass pretty. It was exhibited by Messrs. Veitch at a meeting of the Horticultural Society in April, 1856; they raised it from seeds sent from Guatemala by Mr. G. U. Skinner.

American Species Destitute of Petals.

Unlike the New Zealand species destitute of petals, these have large and usually very showy flowers; indeed, some of them have the largest flowers in the genus. They are of epiphytal habit, growing upon rocks and trees, and some of them produce their flowers on naked branches before the leaves appear, or before they are fully grown out. Two of this section have been in cultivation, but, possibly through their epiphytal nature not being understood, they have been lost. They are all natives of mountains of the north-western part of South America. Until last year only two species had been described; to these I added four, two of which may possibly be extreme forms of the original *F. apetala*.

45. **Lobb's Fuchsia** (*F. macrantha*, *Bot. Mag.*, t. 4233).—A magnificent Fuchsia, first discovered by Mr. Mathews, climbing on trees in the lofty mountains of Andimarca, Peru; but to Mr. William Lobb, while collecting for Messrs. Veitch, the honour is due of having introduced living plants into this country. He found it in woods in the Colombian Andes, at an elevation of about 5000 ft., and Messrs. Veitch exhibited a flowering plant of it at the Horticultural Society's rooms on April 7, 1846. It has short, thick, warty branches, and large, ovate, softly hairy leaves. In the wild specimens, at least, the pendent flowers are borne in clusters near the ends of the branches; in luxuriant specimens they are almost 6 in. long, the tube constituting nearly the whole length. The sepals are only about $\frac{1}{2}$ in. long, and are erect, enclosing the stamens. The colour is a soft rosy-red, passing into yellow and green on the edges and tips of the petals. This fine species is described as a free bloomer, scarcely exceeding 2 ft. high under cultivation. It is to be hoped that somebody will re-introduce it.

46. **Pavon's Fuchsia** (*F. apetala*, *Ruiz and Pavon*, *Fl. Peruv.*, iii., t. 322, fig. B).—The first apetalous Fuchsia described, and although the flowers are not so large as those of *F. macrantha*, it is a very handsome species. It differs mainly from the last in its smaller flowers with relatively longer sepals, in its slightly protruding stamens, and in its larger leaves. A native of Peru and Colombia, formerly, if not still, in cultivation on the Continent.

47. **Jameson's Fuchsia** (*F. insignis*, *Hemsley*, "Journal of Botany," 1876).—Perhaps the showiest of this section, though it has the drawback of being quite leafless during the flowering season. The brilliant scarlet flowers are clustered at the ends of the branches, and they are nearly as large as those of *F. macrantha*, but differing materially in the spreading sepals being more than half as long as the tube. Professor Jameson first discovered it in 1836 in the province of Alansi, Ecuador, at an elevation of 10,000 ft.; and Spruce subsequently detected it on the western side of Mount Azuay. It climbs over trees, attaching itself by roots like Ivy. Not introduced.

48. **Lechler's Fuchsia** (*F. hirsuta*, *Hemsley*, "Journal of Botany," 1876).—This may be no more than a small-flowered variety or state of *F. apetala* with very hairy flowers. Lechler found it growing on moist, shady rocks in Peru.

49. **Linden's Apetalous Fuchsia** (*F. membranacea*, *Hemsley*, "Journal of Botany," 1876). This and the next differ from the preceding species of this section in having fully developed leaves at the time of flowering, and in the flowers being borne singly or in pairs in the axils of the leaves all along the branches. A very distinct Fuchsia, having membranaceous leaves 2 in. to 2 $\frac{1}{2}$ in. long, borne on slender stalks. The scarlet flowers are about 2 in. long, on slender stalks of nearly the same length, and the erect sepals considerably overtop the stamens. Discovered in Caracas by Mr. J. Linden. I have seen only dried specimens.

50. **Willow-leaved Fuchsia** (*F. salicifolia*, *Hemsley*, "Journal of Botany," 1876).—Also a very distinct species, characterised by long, slender, straight branches, shortly-stalked, Willow-like leaves, and shortly-stalked flowers about 3 in. long. Discovered by the late Mr.

Pearce when he was collecting for Messrs. Veitch. He describes it as an epiphyte with pink flowers, growing on Mount Sandillani, in Peru, at an elevation of 7000 ft. to 8000 ft.

New Zealand Species.

This group comprises three or four species, very distinct from all those native of America. In common with the petalless species from the latter country they have alternate leaves; and they also have no petals, or only very small ones. The first is either a rambling shrub or medium-sized tree, according to the locality in which it grows; and the others are small dwarf or trailing shrubs, with slender branches and small leaves.

51. **Trailing Fuchsia** (*F. procumbens*, *R. Conn.*, *Bot. Mag.*, t. 6139; *F. Kirki*, *Hooker*, "Icones," t. 1083, male plant).—A trailing plant, with very slender stems, often several feet long, small roundish leaves, seldom exceeding $\frac{1}{2}$ in. in diameter, and borne on relatively very long and very slender stalks, and small petalless flowers, less than $\frac{1}{4}$ in. long. From the habit of the plant the flowers have acquired an erect position. Although they are so small they are attractive on account of their colouring. The calyx-tube is orange-yellow, passing to green on the outside of the sepals, which are reddish-purple on their upper surface, and turned back in the expanded flowers, and closely appressed against the tube. In this species the sexes are separated, though the male flowers contain imperfect female organs, and the female flowers imperfect stamens; and the blue-anthered stamens vary in length in different plants. Dr. Hooker states that this was introduced into England many years ago by the late Mr. Williams, of Hendon. It was re-introduced about three years ago by Mr. J. Blackett, of Egham, but being a very modest little thing compared with its brilliant kindred which embellish our conservatories, it is only to be found in the gardens of the curious. Its home is on the sandy sea-shores of the warmer parts of New Zealand, where its branches become hard and wiry. I have somewhere seen a statement to the effect that this is hardy in this country, but that means probably that it will survive a mild winter in an unusually favourable situation. I have ascertained that it was cultivated in this country by the gentleman mentioned above in, or previous to 1842.

52. **Colenso's Fuchsia** (*F. Colensoi*, *Hooker*).—This is intermediate between *F. excorticata* and *F. procumbens*, having the flowers of the former and the habit and foliage of the latter. It is not in cultivation, and not yet very well defined; it may be a hybrid between the two species named, or there may be two species mixed up together under this name at Kew. Without fresh specimens it is almost impossible to decide, particularly as many New Zealand plants show a tendency to variation; this wide range of variation is surprising and perplexing to a botanist acquainted only with the relatively constant species forming the vegetation of this country.

53. **New Zealand Tree Fuchsia** (*F. excorticata*, *Linnaeus*, *Bot. Reg.*, t. 857).—According to Sweet, this singular species was introduced in 1821, but a figure of it did not appear till 1824. The figure in the "Botanical Register" quoted above is an excellent representation of the plant. It appears to have been first raised in Mr. Colvill's nursery from seed collected in New Zealand by a Mr. Richardson. If Sweet's date be correct, this was the third or fourth species introduced into European gardens, but it was quickly followed by *F. arborescens* and several others. In favourable situations *F. excorticata* exceeds all others of its genus in size, sometimes forming a trunk 3 ft. in diameter. It varies, however, very much in size, and the usually rather thick branches and trunk are clothed with a ragged, papery bark. The alternate leaves vary in wild specimens from $1\frac{1}{2}$ in. to 3 $\frac{1}{2}$ in. in length, dark green above, and silvery or tawny beneath. The flowers, which are only about $1\frac{1}{2}$ in. long, are very distinct in shape, and change from a yellowish colour tinged with red when the first open to a deep red. At the base the calyx-tube has a spherical expansion, above which it is constricted, and thence it rapidly widens upwards, being relatively very broad at the mouth. The petals are dark purple, less than $\frac{1}{4}$ in. long, or about a third of the length of the spreading sepals. The stamens scarcely exceed the sepals, and have blue anthers on a level with the large globular yellow stigma. What part this very distinct species has played in the parentage of the first hybrids and their descendants it is difficult to say. For my own part, I think it has not hybridized with any of the American species, as I can find no mention of it in connection with any of the numerous early crosses. Donald Beaton, however, in London's "Gardeners' Magazine" for 1835, states that *F. excorticata*, impregnated with the pollen of either *conica* or *globosa*, will produce fac-similes of *F. discolor* or the Port Famine Fuchsia. Of course, without trying the experiment, it would be going too far to assert that this is impossible, but it seems incredible. The following sentence, taken from the same place, is equally open

to doubt; in fact, it is not at all certain that hybridism between distinct species has been so common among Fuchsias as is generally supposed:—"F. conica, gracilis, tenella, virgata, and many more varieties, or perhaps species, may be originated by fertilizing the stigmas of coccinea with the pollen of F. arborescens. This I have proved three times over." Most likely cross-impregnation was not effected, and the result simply natural variation.

UNDERGROUND HOT-WATER PIPES.

I DOUBT if there be any greater waste connected with horticulture than that of heating by the plan very often adopted of uniting several ranges of houses to one boiler. There can be no question as to capability of providing sufficient heat, and as long as the whole apparatus is intact all goes well, but in proportion as the area to be heated is enlarged, so are the chances of failure and breakdowns multiplied. To give the one-boiler system anything like a fair trial the houses must be grouped or concentrated as closely as possible, and even then a vast amount of heat must be lost in its transit to the required points, as the branches from the main pipes must expend their greatest heat in warming underground chambers or drains, while of necessity the returns must be lower, and in many cases liable to be soon eaten through by rust from combined heat and moisture. To guard against these evil effects as far as possible, all pipes that are sunk below the ground-level should be kept as clear as possible of all substances likely to create rust, as should also the pipes for atmospheric heat. I have just been taking out some connecting pipes that have been eaten completely away by being left in contact with the mortar and sand, and so rapid is the decay, that although only fixed fifteen years ago they are now completely useless. It is not only absolutely necessary to guard the main flow and return from anything coming in contact with them, but all stop valves, sockets, and, above all, connecting pipes, should be kept quite clear of the brickwork, merely resting on piers directly on tile or slate, and not bedded in mortar on any consideration. Some soils are doubtless more destructive to iron than others, but it is best to be on the safe side, and to guard against rust in the only effectual way by allowing a free circulation of air to surround all the pipes whether above or below ground. There should also be ample means of access by gratings to examine all underground pipes frequently, so as to remedy any defects

without the labour and annoyance of excavating, &c., where the pipes are buried; for, however skilfully the work may have been performed, a defect may exist in apparently the soundest socket or pipe, and when it does give way (as is usually the case in severe weather, when the apparatus is being heavily taxed), there are few things connected with a gardener's art against which he is so powerless to contend as a stoppage of heating apparatus, and the more complicated and extensive it is the greater the liability of injury, and also of the difficulty of rectifying it. Cast iron is by no means a desirable substance on which to operate, even when experienced workmen are at hand, and although makeshifts are obliged to be extemporized in exceptional cases, the only real remedy for a fracture is to get an entirely new casting of similar patterns. From my own experience I should prefer a medium-sized boiler of sufficient power to heat one, or, at the most, two ranges of houses, and the simpler in design the better, for, however well complicated apparatuses may look on paper, it is quite another matter when they are subjected to every-day use; it is only by actual experience that the defects of even the best arranged apparatus that ever was erected become apparent.

Henham. JAMES GROOM.

THE CATAWISSA TREE ONION.

THIS is a perennial and prolificus Onion, that is to say, like the Potato Onion, it produces small stem bulbs, which if planted either in spring or autumn throw out the first year

The Catawissa Tree Onion.

two or three stems, which in due course reproduce bulblets. These, though scarcely matured, develop into new stems crowned by new bulblets, which frequently produce a third set of shoots, the whole rising to the height of from 2 ft. to 2½ ft. After two years they stop growing, and the trusses become very vigorous, ranging in number from twenty to thirty, each with from ten to twenty bulblets, but less frequently throwing out a second batch of stems. The flavour of the bulbs and shoots is very similar to that of the common Onion; the bulblets may also be used after stripping them of the outside skin, which is very hard. Of the utility and productiveness of this variety Messrs. Vilmorin speak in favourable terms. M.

Grapes at Montreal.—The report of the Fruit Committee of the Montreal Horticultural Society gives the following rules for the management of Grapes in that climate:—1st. Ground thoroughly underdrained. 2nd. Well pulverized garden soil; the richer the better. 3rd. A southern exposure, where the full benefit of the morning sun may be had. Fruit will ripen at least a week sooner if grown against a wall or fence. Protection by means of a belt of trees or fence, against the cold north and east winds, is a great safeguard in our northern climate. 4th. A covering of from 1 in. to 6 in. of earth or other material, in winter. 5th. Constant but not severe pruning; a certain amount of foliage being requisite to bring fruit to perfection.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Azaleas.—I know of no plants more suitable for amateurs to grow than these, whether the object be for decorating the conservatory or for using the flowers in a cut state. Those amateurs who have the means at command of giving them whilst young the treatment hereafter recommended will find that by so doing they will increase in size much quicker than when grown in a colder atmosphere, with the additional advantage that plants grown quickly are most likely to live and flower in a satisfactory manner. In autumn select young, healthy free-growing plants in, let us say, 6-in. pots; let them be wintered in a temperature of from 45° to 50°; they will need shifting about the beginning of March into 9-in. pots, the soil must consist of good fibrous peat, broken into pieces about the size of *Acerus*, adding enough sand to keep it in right condition; after this re-potting the house must be kept a little close. During April and May the night temperature should be from 60° to 65°, and the day temperature 70° to 75°; syringing overhead in the afternoons. Unless in the case of any shoots that are stronger than the rest do not stop them, as a good foundation for the future specimen is what is now wanted. The night temperature during June, July, August, and September, should be from 65° to 70°, and from 75° to 80° in the day. Any blooms they set must be nipped out, and a second growth will be made. By the end of September admit more air, discontinue syringing the plants, and reduce the heat 10° during both day and night. Winter them in the same temperature as mentioned previously. By the beginning of March they should have more heat, and be syringed each afternoon as last spring. When the roots begin to move shift them into 12-in. or 13-in. pots, using soil similar to that previously recommended, and pressing it down firmly. Through the summer treat as last year; about midsummer most of them will set bloom, which should be removed; they will then make a second growth, and by the end of September or middle of October a good crop of buds will be set. A month before this time disperse with the syringing, give more air, let the atmosphere be drier, but do not reduce the temperature too much. Any growths that may show a disposition to outgrow the rest ought to be tied down with their points near the bottom of the plant. Winter as previously; they will bloom freely, but as at the same time they will be full of young growth, they must not be placed in a dry atmosphere or subjected to draughts. If they be pushed on as before and in the same temperature, two growths will again be made. This season do not pot them till the flowering is over; their general management may be the same as previously recommended. As it will now not be advisable for them to make above one growth in a season, they will of course need to be wintered in a cooler temperature—from 36° to 42° by night will do. Their worst insect enemy is thrips, for which the best remedy is washing with Tobacco-water, to each gallon of which has been added 1 oz. of Gishurst; do not wash the mixture off, but let it dry on; fumigation injures the leaves more or less.

Celery.—Some seed may now be sown in pans or boxes in a little warmth; the soil used should be of a fine sandy description, so that when the plants are ready for pricking out, this can be done without injuring their roots, which would occur if it were lumpy and strong, thereby causing a check.

Spring Cabbages.—Where there may not have been enough spring Cabbages planted, the deficiency can be made up by planting those that were in the autumn pricked out in a reserve bed.

Strawberry Beds.—If these have not had their winter dressing, they should be attended to at once. It is better in land that is heavy and retentive to fork over the ground between the rows a few inches deep, not disturbing the roots; where this is not done, and the soil is of the above description, it gets made so solid by the trampling which is unavoidable in gathering the fruit that the rains cannot penetrate, and if weeds be plentiful, they must be got rid of by forking in, for too much soil is lost, and the roots bared if they are hoed up and raked off. However, where good, clean cultivation is practised, there will not be many weeds, and, with the exception of just loosening the top, so as to let the rains get to the roots, the less digging there is in ground occupied by Strawberries the better. Always use the fork where shallow stirring of the soil is requisite.

Peas that were sown in the autumn and are aboveground will derive benefit from the addition of 2 in. of dry sandy soil: let this be done by hand, being careful not to injure or break their stems. A sprinkling of fine ashes on the top will likewise be beneficial, as the ashes will offer a great obstacle to the movements of slugs. Stake the Peas with a few short sticks and thread some white cotton about them to scare away sparrows. To protect them from the wind some branches of Spruce or any material of a similar description may be

put in the ground at a short distance away from them, but on no account must they be near enough to make the Peas draw up in a weakly manner. Where the situation is cold and late, and not favourable for the early sowing of Peas out-of-doors, a gain of a fortnight may be effected by sowing in a frame, pit, or in a cold Vinery. There is no better way of proceeding than to use strips of turf 6 in. wide and about 4 in. thick, placing them on boards with the Grass side downwards. Cut a channel down the centre of the turves about 2 in. deep; here sow the Peas and cover with fine soil. They will quickly begin to grow, and in March can be planted in shallow trenches.

Lawns and Walks.—Let all worm-casts be kept swept from lawns and the Grass rolled. Any walks that want re-gravelling should be attended to at once, so as to afford time for the new gravel to set previous to dry weather; this will be found to effect a great saving in the labour of rolling, and the walks will also be pleasanter to the feet during summer.

Roses, through the extreme mildness of the weather, have made young growths very early, but they must not by any means be pruned yet, as that would cause the eyes that are further down the shoots and yet dormant, to push forward, and they would be almost sure to be killed later in the season.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

January 29.—Finishing the digging of vacant ground. Making ready to sow a second piece of Broad Beans (Early Long-pod). Digging flower borders and among standard Roses. Sowing Dutch Turnips, French Beans for first Bean-house, second Peas (consisting of Laxton's Alpha, Little Gem, and Advanceer), and rows of Spinach between the Peas. Still potting Cattleyas; also cuttings of *Calceolarias*. Shifting Hollyhocks into 6-in. pots. Potting some young *Vallotas*. Putting a few scented *Verbenas* into heat for cuttings; putting in Red and Black Currant and Gooseberry cuttings. Planting Potatoes under wall and in front of Orchid-houses, and sowing a few Radishes among them. Planting a third pit with potted Potatoes. Beginning to layer Carnations for flowering in winter. Putting in 100 more Keen's Seedling Strawberry plants to force. Wrapping *Ageratum* in Moss and putting them in boxes in heat so as to be able to divide them at bedding-out time. Taking a pitful of *Eparis* to conservatory and bringing away Heaths which have done flowering. Shifting young *Begonias*. Putting a few Pinks into first Peach-house. Shifting herbaceous *Calceolarias* into good rough material. Putting *Pelargonium* into greenhouse. Fasting up *Dendrobium*-house and *Lycaste*-house shades. Shading East Indian-house for about two hours during very sunny weather. Cleaning scale off *Camellias*. Syringing *Odontoglossum* overhead twice daily. Washing *Phakopsia* again with insecticide for thrips. Making another frame ready for Carrots and Radishes. Making up Potato-beds in frame ground. Getting all Peach trees pruned that are under glass. Cutting down the winter Heaths. Finishing the pruning of wall and pillar Roses; also that of bush fruits.

Jan. 30.—Digging amongst Currant trees by walk sides. Sowing Cabbage Lettuces; also Cauliflowers in frame. Potting-off late-struck *Christine Pelargonium*; also *Vallotas*, *Amaryllis*, and *Eucharis*. Putting one-year-old Vines into fruiting-pots. Getting ready to prick off *Lobelias*. Putting in *Banvardia* cuttings and cutting down old plants. Putting in fifth crop of Rhubarb. Shifting *Humeas*. Putting all *Fuchsias* into heat. Taking all plants wanted for forcing out of first *Hamburgh*-house. Laying verges. Getting all Vines painted and tied down. Fumigating *Pelargonium* and *Roses*. Giving Vine border a top-dressing of burnt refuse, ashes, loam, old mortar, and farmyard manure. Putting all tree protectors in order. Keeping first Strawberry-house a little drier as blossoms damp. Raising first and second Peach-houses to 55° at night.

Jan. 31.—Sowing *Walcheren* and *London Cauliflower* in heat; also *Lobelia speciosa* in heat, and more *Syon House Cucumber*. Potting Cattleyas, and beginning to shift *Centraureas* into 8-in. pots. Putting in *Petunia* and *Verbena* cuttings. Placing old *Verbenas* in heat for cuttings. Planting *Jerusalem Artichokes* with leaf-soil. Putting in *Eudive* to blanch weakly. Placing *Crocuses* and *Snowdrops* in cold pits. Fumigating *Gardenias*. Disbudding all *Hamburgh Vines* in pit to twelve shoots to a Vine.

February 1. Sowing *Capsicum*, *Tomatoes*, and *Carrots* on leaf beds; also *Lobelia* in heat. Beginning to box *Balu*. Potting *Tigridias* and placing them in Peach-house; also *Tuberose* and planting them in heat. Giving *Gardenias* some *Stauden's*

manure, and afterwards watering them with guano-water once a week. Potting in *Verbena* cuttings; also some cuttings of *Poinsettia*, *Heliotrope*, *Achyranthes*, *Salvia fulgens*, *Fuchsia*, and *Lobelia speciosa*. Planting *Roses* where needed. Potting in another batch of *Asparagus*. Tying down *Raspberry* canes. Watering thoroughly the third *Peach-house* inside. Beginning to sprinkle once a day *Peach trees* which have set their fruit. Manuring and just pricking over the *Asparagus* beds. Finishing the making of tree covers. Clipping *Privet* and *Yew* hedges. Thinning *Radishes* in frames. Placing all *Potato* frames on leaf beds and putting in soil.

Feb. 2.—Sowing two lights of *Radishes* and *Carrots*, making ten lights in all; also incomparable and *Ivery's Celery*. Potting *Isoplepis*, *Selaginella*, and *Cucumber* plants. Shifting *French Beans* sown on Jan. 21 into their fraying pots, and placing them on shelves of second *Vinery*. Potting *Laelia superbiens* in nearly all *Sphagnum*, the pots being crooked to the top. Taking out of heat *Calceolaria* and *Balm* cuttings, all well rooted. Removing *Strawberries* from pit to *Vinery*; top-dressing them with half loam and half manure (fresh droppings). Putting *Maréchal Niel* *Roses* into green-house. Shifting a few young *Fuchsias* and putting them into second *Peach-house*. Beginning to nail *Apricots*. Putting gas tar round *Violet* frames and stopping up all rat-holes. Pulling down shades in *Orchid-house* for first time, just as thermometer reached 80°. Washing *Daphnes*. Getting soil and pots in to warm for next *Beans*. Earthing-up first *Potatoes*. Loosening the *Peach trees* on walls. Beginning to prune *Apricots* and *Peach trees*. Thinning first *Hamburgs*. Cleaning herb-beds. Plants ready for house decoration:—*Hyacinths*, *Narcissus*, *Lily of the Valley*, *Heliotropes*, *Tulips*, *Crocuses*, *Dentzias*, *Cyclamens*, *Primulas*, *Snowdrops*, *Scarlet* and *Scented-leaved Pelargoniums*, *Lilacs*, *Callas*, and *Mignonette*.

Feb. 3.—Sowing *Orangefield* and *Kaye's Tomatoes*. Potting some *Oxalis* and autumn-struck *Heliotrope*; also some *Centaurea* cuttings, and putting them into *Peach-house*. Potting in cuttings of *Cineraria maritima*, *Carnations*, and *Scented Verbenas*. Planting out the first *Cucumbers* in five-light pit. Layering winter *Carnations*. Turning manure for *Celery*. Putting some manure on *Rhubarb* out-of-doors to blanch; also on *Seakale*. Making new *Horse-radish*-bed, taking up old stock in order to be able to prepare ground.

Orchids.

All the plants in the *Orchid-house* should now be inspected, cleansed, and re-arranged, and, while so doing, those which are about starting into new growth should be placed in positions where they can the more readily be observed and tended, or the aphides, which are so fond of the young growths, may attack and injure them beyond recovery. If aphides make their appearance on a few plants only, they should at once be removed by means of a sponge and weak *Tobacco-water*; but if they be generally distributed about the house, it is better to effect their removal by gentle and repeated fumigations. One of the great advantages of having a small lobby attached to the *Orchid-house* is, that plants requiring fumigation can at any time be moved into it, and fumigated there without subjecting the bulk of them to the risk of injury, which, unless the operation is carried out with the greatest care, generally happens. As the sun gets stronger more opportunities will be afforded for giving air, and this should be constantly done in order to retard the young growths and make them the more sturdy and fit to grow strongly when the proper time arrives. Nothing is more destructive to *Orchids* than the close, artificially-heated atmosphere in which they are too often kept during the winter; it is this that causes the loss of so many delicate-growing kinds, too high a temperature and too little air being more fatal to them during the resting than the growing season. During such weather as we have had for some time past (if we could insure the keeping off of frost), the *New Granada* and other cold-house plants would do better in a pit not heated by artificial means than in an *Orchid-house*, unless the latter is well managed with respect to temperature and ventilation.

—JAMES O'BRIEN.

Covering Back Walls of Greenhouses.—One of the most easily established plants either on the back walls of greenhouses or on inside rockwork is *Asplenium bulbiferum*. The young plants form and commence to grow on the mother plant, and if taken off with the portion of the old frond attached to them, and just pegged on to the surface of rockwork, or into the interstices of the brick-work itself, they will soon take root and establish themselves without further care. *Asplenium Belangeri* may also be utilized in the same manner, but it requires a stove, whereas *A. bulbiferum* is almost hardy; the individual fronds, too, being of good substance, last a long time in perfection.—J. CORNHILL, *Byfleet*.

MUSHROOMS AND MUSHROOM-HOUSES.

DURING the past season the crop of *Mushrooms* in the open fields was so unusually plentiful that from an old pasture a man filled a peck basket without moving from one spot. It is no exaggeration to say that a cart might have been loaded for several successive mornings from this same field at the height of the *Mushroom* season, and this abundance has been more or less general. The month of July and first weeks of August were unusually hot and dry, the Grass was burnt up, and the exposed soil became very much heated, which no doubt favourably developed the growth of the *Mushroom* underground; copious falls of rain succeeded at the end of August and during September, which revived the growth of Grass and with it that of the *Mushroom*. We may therefore take a hint from Nature in this instance, and turn it to good account in the culture of the *Mushroom* indoors in winter. The story of *Mushroom*-growing has been often written, each writer relating how he has best succeeded in the matter. The mode adopted by the French in the catacombs of Paris is most interesting and suggestive. The few remarks now to be made shall only be as a sequel to what I consider was the cause of the abundant crop of last autumn. A season of dryness and considerable heat seems to be essential to success in the early stages of the growth of the *Mushroom*, that is, in order that the spawn may run and permeate the soil. In making *Mushroom*-beds in winter it is sometimes difficult to secure manure in a sufficiently dry state, and in such a season as the present it is impracticable to dry it even in open sheds, but it must be sufficiently dry to be in good order for *Mushroom* growing. The usual process of throwing up the manure in a heap to heat, and so dissipate much of its moisture, is simply wasting the most essential elements of the manure. Suppose it to be brought from the stable-yard in a rough, fresh state every morning, or, it may be, at longer intervals, and to have become considerably wetted with rain, the droppings should be shaken out roughly, as the straw is in much too great a proportion to admit of its being used in the bulk. No objection is made, however, to the half being short straw. When shaken out it should be wheeled into an open shed and spread out about 1 ft. or more thick, and twice turned at an interval of three or four days. While yet comparatively fresh sufficient should be taken to the *Mushroom-house* to make a bed. In the *Mushroom-house* should be stored a quantity of thoroughly dry soil from a pasture where *Mushrooms* grow naturally, the turf having been pared off and secured when dry in the summer, but now warm and ready for use on the floor of the house; the manure should be mixed with some of this soil in the proportion of one barrow-load to three of manure, more or less, according to the state of the latter as to moisture. The mixture being then beaten firmly into the shelf or bed, a day or two should be allowed to elapse to let the heat pervade the bed uniformly, when the spawn should be planted just under the surface of the manure, and the bed soiled at once with ordinary garden mould sufficiently wet to make a solid cake all over the surface about 1 in. thick. After another day or two the bed should be covered over with dry straw. The temperature of the house should be maintained at about 70°, and the atmosphere saturated with moisture, water being freely sprinkled on the floor and walls of the house. The dry soil thus mixed with the manure absorbs any superabundant moisture, and checks overheating, so that it is always safe to put in the spawn at once. There is one point of the utility of which may be doubtful, and that is the soiling of the bed, for if the bed be formed on open spars of timber or iron bars for a bottom, *Mushrooms* will sometimes be found to grow as plentifully through the bottom of the bed as on the top, and if one's memory may be depended on, the French are described as not soiling their underground beds at all.

In about a month or five weeks the surface of the soil will be somewhat dry, and *Mushrooms* like pin-heads will be appearing all over the bed; the straw should therefore be removed. And now let us take another hint from the past season. Get ready a quantity of tepid water of the same temperature as that of the house—soft rain-water, if possible—and proceed to water the bed slowly and gently, in order to allow the water to sink in evenly. The bed should not be soaked; a safe quantity will be at the rate of 1½ gallons to the

square yard, supposing the bed to be 1 ft. thick. The Mushrooms will now swell rapidly and abundantly. Good Mushrooms are very juicy and succulent, and must absorb a large amount of moisture from the bed. I fear, therefore, that it is a common mistake to allow beds to be too dry at this stage through fear of doing them some injury. There need, however, be no hesitation as to watering if everything have gone on rightly up to this time. No doubt Mushrooms are much aided in their growth by atmospheric moisture derived from the autumn dews, which are usually very heavy, and Mushrooms are saturated in the early mornings in the fields. I once knew an old gardener remarkably successful in the culture of the Mushroom who soiled his beds with thin turf the Grassy side upwards, and who kept the Grass alive and wet with fine spray from the syringe, the Mushrooms coming up among the Grass. When Mushroom-beds begin to show signs of waning, in about a fortnight or three weeks, a similar watering to the first should be given, when the second yield will be as good as the first; and a third watering, or even more, may be given with sufficient return to pay for the labour and space if plenty of room be at command, but if space be limited, beds may be cleared out after six weeks' yield. I find small beds preferable to large ones for the daily supply of a family, so that portions of beds may be made at short intervals. Shelves, divided into lengths of 9 ft. by 6 ft. wide, will be handy compartments in which to make weekly, or even fortnightly beds, for the supply of say half a peck of Mushrooms per day. Very much will, of course, depend on the quality of the spawn, for if this be not good, no amount of labour will be of any avail. Spawn should be procured not more than twelve months old, for although it will keep tolerably good for a much longer period if thoroughly dry and sweet, still I like it freshly made, just as I like to sow new seeds for a crop of Peas or other vegetables. I often hear of and see Mushrooms growing quite spontaneously out of beds which have never been spawned at all, a proof of which I have just noticed. An old Mushroom-bed, which had never been spawned, was cleaned out to make room for a fresh bed; it had become very dry, and, when too late, we found that the whole of the manure had become by some means quite full of spawn, possibly by fragments having been accidentally dropped upon it. It was evident that if the bed had been soiled and watered like the others, a crop of Mushrooms would have been the result.

W. D. C.

ANOTHER ORNAMENTAL GRASS.

(*SACCHARUM ÆGYPTIACUM*).

GRASSES of noble habit have of late years deservedly obtained popularity, and especially has this been so since the introduction of the Pampas Grass, the latter having proved so satisfactory not only in large gardens, but also in the grounds attached to almost every suburban villa. The plant, of which the annexed is an representation, is also a Grass attaining, under favourable circumstances, a height of from 6 ft. to 8 ft., and well deserving a trial wherever its ally *Gymnothrix latifolia* has been found to succeed. As will be seen, it forms a

Saccharum ægyptiacum.

dense plumose tuft of handsome foliage, and even in northern localities, where it will not succeed well in the open air, it deserves a place along with the *Gymnothrix* in the bed of a cool conservatory, in which its light and graceful habit will be found to contrast favourably with that of Fan Palms, Tree Ferns, and half-hardy *Araucarias*. It may be seen during the summer months in the Parc Monceau and in other Parisian gardens, whence so many beautiful half-hardy exotics have been introduced into English gardens.

B.

MAGNOLIAS.

MAGNOLIAS, where they succeed, are among the grandest of flowering shrubs or rather small trees. Unfortunately the evergreen species are not sufficiently hardy to thrive without protection in winter, except in the more southern counties, and even there they make but slow progress as standard trees; a few specimens with which I am acquainted lose their leaves in very severe winters, and their young wood is even injured. *M. grandiflora*, one of the finest of the whole family, succeeds against a south wall in most parts of the king-

dom. I have seen a large tree of it in a sheltered corner in Murrayshire. Here, in Dorsetshire, are grand trees of it 30 ft. high, and if the wall against which they grow were higher they seem capable of attaining a height of 50 ft. I have cut from it repeatedly growths 6 ft. long which were overtopping the wall, and curiously enough those succulent branches never receive any injury from exposure to frost and north winds; hardiness seems much to depend on the protection given to the roots and boles of the trees. Of all the varieties of *Magnolia*, *M. grandiflora exoniensis* is the best; its foliage is of a paler green than that of the species, more regular in shape, the margin recurved, and the under side more thickly covered with a brown tomentum; it is a most prolific flowerer,

and continues in bloom from June to October, and even later in favourable seasons. The ordinary *M. grandiflora* is a more robust plant altogether than *exoniensis*; it has more shining, Holly-green foliage, which is not so handsomely shaped and broader than that of *exoniensis*, and it does not flower so freely, but it sometimes ripens its seeds, which *exoniensis* does not. *M. grandiflora* may be readily propagated by means of layers, and it will grow in any well-drained soil—a sandy yellow loam seems to suit it perfectly. *M. tripetala*, a deciduous species, sometimes called the Umbrella Magnolia, makes a very handsome lawn tree; it forms a round-headed specimen, 20 ft. high and 30 ft. in diameter of branches. When old these attain a pendulous habit, the points turning up again like the branches of a candelabrum. The leaves, which are large and handsome, are arranged in whorls round the points of the branches, and hanging down by their own weight are not unaptly likened to so many parasols or a huge candelabrum. Suckers from the root of this species made growths last season 5 ft. long and as thick as one's thumb. The flowers which appear in spring are white and very large, but by no means beautiful, nor do they possess the most agreeable scent. This species seeds freely here, and the seeds, which are like small Coffee berries, are enclosed in a red pulpy coat, which is again enclosed in a pod. Sometimes two seeds are in one pod, and these pods are arranged on a terminal spike something in the form of a cone; the pods open like those of the Furze, and the seeds drop out in November. Seeds of it are obtained in abundance in France. Of *Magnolia purpurea*, which is a free-flowering deciduous species, the variety called *gracilis* is the best; it is of twiggy, pendulous habit, and makes a handsome floriferous shrub when grown in a situation which suits it. The flowers, which are a pale purple in colour, open in May and June, and last a long time on the tree, or when cut, in glasses. I have not seen it ripen seeds. I have many plants of it growing in different situations, and I find that it does not succeed well in dry, exposed localities, or in dry soils. In a shaded, moist position it develops its foliage much more satisfactorily, and every twig is terminated by a handsome pendulous blossom. Our best bush of this *Magnolia* is associated with some very fine specimens of *Rhododendrons*, which make foliage more like that of a common Laurel than a *Rhododendron*. *M. glauca* is a handsomer plant than the kind last named so far as foliage is concerned; it requires a moist soil and somewhat shaded position. The fine glaucous blue of the under-side of the leaves makes it distinct from all other *Magnolias*, but to have well-developed foliage and a plant worth looking at it must have an open peaty or sandy soil and abundance of moisture at the root. The flowers, which are of a creamy-white colour, have stiff leathery petals. They are about the size of an egg-cup, and are deliciously scented. It is indeed the sweetest *Magnolia* with which I am acquainted, except, perhaps, *M. fuscata*, which, although from another hemisphere, should prove equally hardy.

Canford, Dorset.

W. D.

GOLDEN VARIEGATED DECIDUOUS TREES.

PREPARATORY to commencing his work, the painter naturally examines closely the pigments with which it is to be wrought, and judges are wont to say now-a-days that marked loss in enduring qualities may be detected in the fading, adulterated tints of many modern pictures. In like manner, the designer of artificial landscapes, amateur or professional, needs to study well the nature of his material, for the simple reason that living plants exceed dead mineral paints in delicacy and complexity. He must secure health, hardness, and the native symmetry that comes by intelligent pruning. He must know habits and capacities, that he may be able to arrange for future effects on maturity, and accomplish certain more immediate results. But, above all, he must have variety and abundance of colour to give the indefinable finish of contrast, shading, and harmony that is essential to the perfection of a noble picture. To assist in accomplishing this to a greater or less degree, we ("Moore's Rural") propose to remark on a few of the most prominent and effective varieties with curious-coloured leaves, commencing with those of a distinct golden type. In general terms, we may say, by the way, that all forms of variegated shrubs and trees should be brought forward, conspicuously, near walks, and individual plants of each group disposed on the principle of large to the rear and small to the front. The composi-

tion of colours will, of course, be controlled by personal taste. It may be well to notice also that all variegated trees tend to dwarf forms than those of the parent species.

GOLDEN ALDER (*Alnus glutinosa aurea*) is a striking tree of pure gold colour and much beauty.

GOLDEN ASH, as represented by two very similar varieties, *Fraxinus americana acucubefolia* and *punctata*, spotted more or less with gold, is hardy, distinct, and enduring, resembling, as usual, the parent in general form.

GOLDEN CATALPA (*Catalpa syringifolia aurea*), is broadly blotched with gold, and has the large, massive character of leaf, and round, spreading head of the parent.

ROESSELL'S GOLDEN ELM (*Ulmus campestris aurea*) is a dwarf form of the English Elm, with leaves richly suffused with gold. It is an enduring variety and a decided acquisition.

GOLDEN HORNBEAM (*Carpinus Betulus aurea*) is distinctly marked with yellow over half the surface of the leaves, and has the parent's sturdy habit and persistent retention of foliage in autumn.

GOLDEN HORSE CHESTNUT (*Aesculus rubicunda aurea*) has curious leaves, margined with gold in wavy masses, and is a remarkable and valuable form, of much larger habit than the last.

GOLDEN MAGNOLIA (*Magnolia acuminata aurea*) is finely marked, and well deserving of more extended employment.

GOLDEN JAPANESE MAPLE (*Acer japonicum aureum*) has probably the most exquisite colouring of all Golden-leaved trees. Its type is dwarf, and allied only to Japanese forms, but the round, scalloped leaf is shaded and tinted with soft gold on convex surfaces in a manner most marvellous. The variety is very rare and difficult to propagate, although, in common with all Japanese Maples, well suited to American summers and winters.

GOLDEN Sycamore (*Acer pseudoplatanus aureum*) has a very decided golden colour tinging its broad leaf, but, more than most others of the class, it loses this valued tint as the season advances.

CONCORDIA OAK (*Quercus pedunculata concordia*) has, and deserves, the very highest rank for purely golden leaves and sturdy, enduring habit. Its size at maturity equals that of the ordinary Oak.

GOLDEN OAK (*Quercus pedunculata aurea viridis*), another variety, is still rarer and, if possible, more beautiful than the last, with a more refined type of beauty. It is broadly blotched, or variegated, with yellow.

GOLDEN PLANE TREE (*Platanus occidentalis aurea*) has all the virtues and defects of the parent, and is finely tinged with yellow.

GOLDEN TULIP TREE (*Liriodendron tulipifera aurea*) is as noble an acquisition as the parent would be considered if recently introduced. The leaves are very broadly margined with permanent gold.

All, or most all, of these Golden-leaved trees are, and must long remain somewhat expensive, partly from rarity, and partly from the necessity of grafting to retain their colours in perfection. Seedlings prove so variable in their tendency to revert back to the original green type, that little worth should be attached to them, and layers, with their ill-formed system of roots, afford so crude a method of propagation that we can but take the more expensive grafted plant.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Holly Berries Two Years on the Plant.—It is not unusual for the Balearic Holly to be seen in red berry—as referred to by "J. S. W." (see p. 48)—for two seasons. I have not observed this peculiarity in any other variety of Holly, but I have frequently seen the berries remain the second year on the variety just named.—C. M'D.

The Blue Gum Tree.—Californians announce a valuable quality in the *Eucalyptus globulus*. It is asserted that it will successfully resist the ravages of the teredo when placed in salt water, and as it does not rot readily, will, it is claimed, make valuable piles for wharf use in harbours. Should that be proven, their growth can be made to pay a better profit than any other kind of forest tree, as they will, under favourable circumstances, attain a sufficient size to be made into piles in from five to eight years.

Hardiness of *Paulownia imperialis* (see p. 47).—A plant of this about 15 ft. high grew twenty-five years ago in the border of the flower garden at Ash Grove, near Sevenoaks, where it was perfectly hardy. The situation was very cold, being on the top of a hill, but it was thoroughly drained, the subsoil being gravel. I do not recollect its flowering; it must have been planted at least ten years before by the late Mr. John Wells, who was many years gardener there. If it escaped the severe winters of 1869 and 1866 and is still standing, it must by this time be a fine specimen.—JOHN GARLAND, *Killerton Exeter*.

Mistletoe Chemically Considered.—MM. Grandean & Bouton have found—
1. That the composition of the stem of the Mistletoe differs essentially from that of the species of trees on which it grows. 2. That the composition varies with the species. 3. That it contains much more potash and phosphoric acid than its supporting trees, and much less lime. 4. That it seems to live on the tree like a plant on the soil; it takes from the yellow parts gorged with nutritive juices, the incombustible matters necessary for its organization.

CYCLAMENS AND THEIR MANAGEMENT.

With the exception of two-year-old bulbs, my Cyclamens are, as a rule, at their best during November and December. I sow some seed annually, and only flower the same bulbs twice. In order to have good plants with an abundance of flower and foliage during the months just named, I sow my seed in the beginning of the year in shallow seed pans, but previous to sowing, I soak it for an hour in water, as I find by so doing that it germinates three or four days sooner than it otherwise would. When sown the pans are placed upon a shelf, close to the glass, in a stove, and there they remain until the young plants are strong enough to be potted off into thumb-pots in leaf-mould, loam, and sand. They are then replaced upon the same shelf for some six weeks, when they are removed to a Pine-pit, and shifted into larger pots as required, using leaf-mould, maiden loam, peat, cow manure, and sand in about equal proportions. When growing freely they must be well supplied with water, and I allow them to remain in the pit in question until the middle of August, when they are taken out and placed in a cool frame, or under a hedge or a north wall. Here they may remain until October when they are removed to the greenhouse, where they soon begin to show signs of flowering, and the result is good foliage and abundance of blossom, and that in the short space of ten months from the sowing of the seed, the pots used being 18 and 32-sized ones. I water them pretty freely with soot-water during the height of their growing season. After they have ceased flowering, they are put out into a cool house and kept watered until the leaves show signs of decay, when it is withheld. As soon as early spring frosts are over, they are taken out-of-doors and set under a north-west wall, and there they remain exposed to all weathers until about the first week in August, when they are shaken out and put into a small pot, using the same material as recommended. I now place them in a gentle heat for a month or so, when, if all goes well, they will need a final shift into 32-sized pots; they are then taken to the greenhouse where they come into flower just as the seedlings did. The best are selected for seed-bearing for next season, and the rest are thrown away. In this way I keep up a stock of good flowering bulbs. Williams' strain is that which I like best.—JAMES GIBBS, *Chartham Park*.

Nut Bushes in Flower.—I can remember no season in which there has been such an extraordinary display of catkins on Nut bushes as there is this year, and I find that the little crimson female flowers are also very plentiful. The trees thus adorned have a very beautiful appearance; and with the fine open weather which we are now experiencing they will doubtless set a heavy crop of fruit. They have been in bloom for the last fortnight or three weeks. I may also add that I have seldom seen a better show of bloom-buds on all kinds of fruit trees than there is this year. Let us, therefore, hope that we may have a continuance of open weather, otherwise our prospects of an abundant fruit crop will, I fear, be doomed.—J. TAYLOR, *Hardwicke Grange*.

Crocuses Eaten by Rats and Mice.—"Catch and kill them" (see p. 60) is doubtless a good way of getting rid of rats and mice, but how is that to be done? The best garden mouse trap with which I am acquainted is a common stone pickling jar. Get a good-sized one, or as many as may be thought desirable; well grease the rim and a little way down inside with lard, and dig a hole near where the mice resort, so as to place the top of the jar level with the surface of the ground; then half fill the jar with water. This trap, if occasionally greased, and kept supplied with water when necessary, will soon reduce their numbers: I have taken six or seven every morning from one jar. Rats are more difficult to catch, being very cautious, and if caught in common iron traps they will eat through any plant within their reach, even a good-sized stem of a Grape Vine, as I have known them to do to my cost, when trapping some that had gained access through holes into a Vinery, in which they made "more free than welcome" with the Grapes. Iron or steel spring traps are also dangerous where cats or dogs are kept, but where these do not exist they are best—*i.e.*, if carefully hidden; a little long soft Grass lightly laid over them, and over that some fine soil, so that the bait only is seen, will generally be found the best plan of setting them; but if they can be placed in their runs baiting is unnecessary.—R. R., *Mansfield, Notts*.

Eranthemum pulchellum.—Considering the scarcity of blue-flowering plants at this time of year, this valuable, free-flowering old favourite deserves to be often met with than it is. Well-grown plants of it may now be found in one of the houses at Fulham Palace. They are grown in 6-in. pots, and are 2 ft. high, bushy, and well furnished with large, healthy foliage and beautiful blue blossoms, which, when associated as they are with Poinsettias, Euphorbias, and other red-flowered plants, are very effective.—J. B.

NEW GARDEN TOOL.

The annexed engraving represents a somewhat novel invention in the way of garden tools; it combines in one a small rake, spade, Dutch and draw hoe, and a fork, one and all of which will doubtless be found useful when working amongst

choice plants or seed-beds where implements of a larger size could not be safely employed. Its inventor is Mr. James Blyde, of Spital Hill, Sheffield. S.

ROYAL HORTICULTURAL SOCIETY.

By a letter from this Society which lately appeared in the "Times," it seems that the Council have determined to continue the South Kensington Gardens on their former footing, and to make them as attractive to the residents in their neighbourhood, and of London generally, as the means and nature of the Society will permit. Oh, most lame and impotent conclusion! After all that has passed, the Society to be thrown back into the arms of the South Kensington esnarer, and its existence to be continued as a parasite on a rich London district! Is it not about time to form a new society—a national Society of Horticulture—which will be maintained by the now great and every-day-increasing body of horticulturists throughout the country? I have too many ties to the old Society, and too many friends among those who work it, to make me like to take an active part in raising a new one, but if any competent energetic man will come forward who, partly for the love of horticulture, and partly for an occupation and a post, is disposed to work the matter, I will show him that there is abundance of power and will throughout the country to found a representative society, which only requires being brought together and organized. And in the meantime, as there may be another turn of the wheel, and the Council may be driven to seek their main support from the more earnest horticulturists, let me beg those good horticulturists who are collecting names of world-be Guinea Fellows of the society when it is free to increase their exertions rather than relax them.

Heathcote, Weybridge Heath.

GEORGE F. WILSON.

NOTES AND QUESTIONS—VARIOUS.

Echin fastuosum hardy in Ireland.—In reference to the notice (see p. 41) regarding the hardness of *Echin fastuosum* in this country, I beg to say that I have been long familiar with it growing out-of-doors, and that, too, in Westmeath.—JOHN BAIR, 12, *Pembroke Road, Dublin*.

Coloured Primroses.—Mr. Fish asks (p. 61) why coloured Primroses flower the earliest? With us the Double White had many fully expanded blooms on it at Christmas—certainly as many, if not more, than any dark coloured one. My impression is, that cultivation has much to do with precocity of flowering.—J. G., *Henham*.

Long-stalked Violets.—The Czar Violet mentioned by Mr. Fish (see p. 25) is excellent in this respect. We have a six-light pit full of Violets, most of them being the Czar, from which we gather daily. They are particularly useful in bouquet making, and when associated with white Camellias or Eucharis, little else is wanted. If a little colouring be desired, that useful winter-flowering plant *Ephiphylllum truncatum* will supply it.—R. GILBERT, *Burghley*.

Derbyshire Spar.—"D." (see p. 60) complains of the expense of this spar, and suggests that agents should deliver it in different parts of the country carriage free. This is an excellent suggestion, as we find that the carriage of a truck load comes to more money than the spar itself; but we can scarcely call ourselves victimised if we get it at the cheapest rate, whether wholesale or retail, in which carriage is included.—J. G.

Mistletoe on the Hawthorn.—I observe in your issue of January 6 the following:—"We have already heard of a successful attempt to work the Mistletoe upon the Hawthorn, and so produce neat berried beads." Now that the Wye Valley Railway (from Chepstow to Monmouth) is opened, one of the most beautiful rides in England is that from Chepstow to Ross, and if any of your readers travelling by that line will stop at Bigswear Station and give me a call, I shall be happy to show them at least a dozen Hawthorn trees with bunches of Mistletoe growing upon them just as naturally as that parasite grows on the Apple or Poplar tree.—H. R. HERBERT, *The Glyn, Whitebrook, near Monmouth*.

Violas and Drought.—"T. S." (see p. 60) would appear to be generally unfortunate with Violas in all seasons, both wet and dry; I therefore conclude that he either has a poor selection or that they fail through some local cause. During the late exceptionally dry season I saw them used effectively much further south than here, and few dwarf-blooming plants flower more continuously. The improvement effected during the last few years on the old *Viola cornuta* is a proof that growers have not, as a rule, selected this class of plants to out-of-the-way corners of mixed borders, but have brought them prominently into the front rank amongst bedding plants.—HENHAM.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

NOTES ON LILIES.

I AM fond of Lilies, but unfortunately for me my only plant of *Lilium Wallichianum* is going to bloom at my home at Bingham, in Nottinghamshire, while I am in Cardigan; therefore I fear I shall not see it. Dr. Moore, of Glasnevin, told me that he was the first to grow this Lily, but somehow he has never succeeded since; doubtless it requires greenhouse treatment, and does not begin to grow till many months after other Lilies. My bulb showed no signs of growth till the middle of July, and I began to think it never would; but it then began to grow vigorously, and was in first-rate condition when I last saw it. My plants of *L. auratum* have been very fine this year and I will give my experience of imported bulbs. Last January I bought fifty at Stevens', and planted them in a bed of loam, sand, and leaf-mould on the north side of a Yew fence, so that the sun did not scorch the soil in hot weather; they soon began to develop, and all made strong growth during the spring, but being small bulbs, I did not expect them to make much progress the first year. Some grew 3 ft. high, some 4 ft. or more, and bore from four to seven flowers, of which I removed all but two, in order to prevent the bulb being weakened by carrying too many flowers the first season. Nearly every Lily was different—some being striped with magenta, some with hardly any spots, and some with many spots; one of them was a very fine variety with a deep magenta stripe running almost into the centre of the flower; this magenta, however, turned brown after the first day, but I have never seen and never expect to see an *Auratum* Lily banded with pure scarlet as described in nurserymen's catalogues. The so-called *L. rubro-vittatum* sold at Stevens' were not particularly highly-marked varieties of *auratum*. I have had one *L. auratum* stem about 9 ft. high, and one with seventeen flowers on it; and I have had one gigantic flower 10½ in. across the bloom, and measuring across the fully expanded petals from tip to tip 16 in. I have heard it asserted that Mr. McIntosh's Lilies at Weybridge were 18 ft. high, and on inquiry Mr. McIntosh courteously forwarded me the following particulars of these wonderful Lilies:—"In reference to the height," he says, "the highest *L. auratum* we have yet had was last year, a bulb with two stems, one of which measured from the ground-level to the top of the stem 11 ft. 2 in.; the same Lily has again had two stems, but the highest did not measure above 10 ft. 8 in., and the other was a little shorter. I expect that this difference in height was caused by the very cold and backward spring and the subsequent very hot summer, for I could not conceive any other reason why it should not have been taller rather than shorter than that of the previous year, judging from the size and volume of the stem, which measured about 3½ in. in circumference, and each year since I have had it it has increased in size. With me the general height of *L. auratum* this year varied from 6 ft. to 9 ft. and upwards. As to the number of flowers on a single stem, we have had some this year with thirty-seven; last year one with a fasciated stem bore seventy-eight. I do not consider this year that they have progressed so well with me as when the sun has been less powerful. I have just succeeded in flowering *Lilium neilgherrense* out-of-doors, the first, I believe, that has flowered in this county; it has now gone off after being out about a week; the stem was 4 ft. 7 in. high, and the flower measured about 7 in. across." It would have been interesting if Mr. McIntosh had mentioned how deep these Lilies had been planted. Cultivators sometimes tell me that they plant Lilies from 18 in. to 22 in. deep, but in this cold county the sun's influence is not strong enough at that depth to bring up the young growths in spring. Possibly the holes were made 18 in. deep, and the bulbs themselves are not more than 10 in. deep in the ground; I believe 8 in. is the proper depth for the finest bulbs, and then only with light soil above. I know that the bulbs are not injured by frost, and I do not think they are by wet, because I

have a small bulb about 10 in. deep in ground that was quite boggy, which yielded seventeen fine flowers this summer, and was much earlier in its growth (though not in its flowering) than any of the Lilies planted in drier soils. I always put sand round the bulb; it prevents the snails and slugs working into the scales.

Since writing the above at Cardigan I have returned to my garden. I have lately been lifting my plants of *L. auratum* and planting them in the open border; they turned out fine, healthy bulbs, and are growing well; some had flowered without making a single root below the bulb, the flowers and stalks being entirely supported by the roots from the stems above the bulb. These roots that are now forming under the bulb are manifestly increasing and feeding it, and then the bulb throws up a stem which is in turn in a great measure supported by its roots above the bulb. This is a good argument for tolerably deep planting. *L. speciosum* and *L. auratum* should never be grown in pots with no soil above the bulb. Some Lilies seem to make no root-growth above the bulb. *Lilium croceum* does not, nor do the Martagon Lilies; such should evidently not be planted deeper than from 3 in. to 4 in. Everybody who loves hardy flowers should have the white Martagon, on account of its loveliness in form and colour; next to it I should place Martagon dalmaticum var. *Catani*, a blackish-purple Lily—to my mind a royal colour. My white Martagon grows freely in turfy loam and seeds freely, and I have no doubt that all the Martagons will do well in that soil. *Lilium colchicum*, otherwise known as *L. monadelphum* and *L. Szovitzianum*, is a grand Lily for the herbaceous border, delicate in scent and very distinct in every way; it grows about 4 ft. high, and has large citron-coloured flowers spotted with black. There is also a perfectly pure yellow variety without spots, *L. chalconicum* (the Turk's-cap Lily), which is known to all, but few people have seen the large variety known as *L. chalconicum majus*. Lilies of the chalconicum variety grow superbly in the sandy soil of Glasnevin, and you could find many stems with a corona of six or seven flowers, but this form of *L. c. majus* eclipsed them all; there was only one flower on a strong stem, but that flower was almost as big as a bloom of *L. colchicum*, very much marked and ribbed with deeper red. This will be a grand form for our gardens. I was well pleased with my journey to Ireland, for there I saw the true *L. longiflorum eximium* in Dr. Moore's nursery in the Botanic Gardens. This Lily is as completely distinct from *L. longiflorum* as *L. auratum* is from *L. speciosum*, though I do not suppose the plant I saw had attained its full proportions. I think the tube must have been some 9½ in. in length, and creamy-white in colour. It was quite different from the Lily I received last year from Dr. Wallace as *Lilium eximium*, and whether it was quite the same as Mr. Wilson's variety, which is completely distinct from *L. longiflorum*, I cannot determine until I see them side by side. Mr. Wilson's variety, judging by a photograph, is very much longer in its tube than the normal form, much more reflexed, and larger in all its parts. The one at Glasnevin seemed to me longer still than *L. longiflorum Wilsoni*. While on the subject of white Lilies I have this year bloomed *L. auratum* var. *virginale*, a pure white with no spots, but of a pale lemon colour, very distinct, but the whitest of all Lilies, and whiter even than the White Ramanas Rose (*Rosa rugosa alba*), is the flower of the variegated *L. candidum*. This variety and *L. candidum speciosum* bloom with me at least a week later than the normal type, though the botanical authorities declare *L. speciosum* to be the earlier form of *L. candidum*. It blooms later with me. I believe we may set down *L. candidum* with golden foliage as the whitest of all hardy plants; the foliage, also, is very ornamental in winter and spring. A grand variety for the open border is *L. Browni*; it is a very large form of *L. longiflorum* with rich chocolate exterior, and such stamens. The petals are reflexed to such an extent, that one might imagine the flower had been invented by some idealizer. It will succeed perfectly in the open border planted in turfy loam. I have not yet seen *L. longiflorum* succeed untouched in a cold climate; it always comes up too soon and gets caught by March winds, but I firmly believe *L. Browni* does not suffer from the diseases common to *L. longiflorum*. I have never succeeded well with *L. speciosum* and its varieties, though

I have bought from time to time most of the highly-described varieties; with me they were in no way different from the ordinary forms. I have still a liking for the variety known as *L. purpuratum*, but I have never seen such magnificently coloured plants of *L. speciosum* as those grown by the famous Abyssinian traveller, Mr. Mansfield Parkyns, at Woodborough, in this cold county of Notts. His soil is good rich, unctuous, clayey loam, rather red in colour. How is it that the bulbs grown in Holland are so much finer than those grown in England? *Lilium concolor* flowered well in the open border, and I believe it will become a great favourite where the smaller and more delicate herbaceous plants are appreciated. Whoever grows *Omphalodes Luciliae* ought to grow *Lilium concolor*. The latter has stems 18 in. high, and exquisite little red flowers spotted with deeper red, opening like falling stars, and afterwards becoming reflexed. *Lilium tigrinum splendens* is of course the future Tiger Lily of our gardens. I saw a splendid specimen at Woodborough, and expect to learn much from that garden in the future. The double Tiger Lily is a grand plant when properly grown, and I think well of the form called *L. tigrinum erectum*; the flowers being set at right angles with the stem appear very showy. I was much gratified by the sight of a glorious plant of *Lilium giganteum*, with fantail stem, growing in Mr. Morgan's garden at Cardigan. This plant is in strong loam, and is always left to itself, young bulbs taking the place of the exhausted growths. It was growing in the full sun in front of a greenhouse, and the *Belladonna Lilies* later in the year were a perfect picture, but mine are quite a failure; I believe our climate is too cold for these *Amaryllids* and for *Lilium giganteum*, though I mean to give both a fair trial. I have planted some bulbs of *L. auratum* in silt brought down by a neighbouring stream, to see how that will suit them. For these bulbs I removed nearly a ton of soil from my garden, and in its place introduced an equal quantity of this silt. I believe the Californian Lilies would grow vigorously in this soil, and I mean to try the Washington Lilies in it. I saw some fine spikes of these Lilies at Glasnevin, but the bloom was past its best. Again, let me advise all cultivators to grow in turfy loam *Lilium excelsum* for the backs of herbaceous borders, and not to be content till they are 7 ft. high. Other Lilies for the herbaceous border are *L. auratum*, *tigrinum splendens*, *candidum*, *umbellatum*, *incomparabile*, and *Brownii*.

Bingham, Nottinghamshire.

FRANK MILES.

Ferulas in Spring.—Among the *Ferulas* now vigorously pushing up their graceful plumes in the Paris Garden of Plants may be noticed *F. ferulago*, *F. neapolitana*, *F. tingitana*, *F. communis*, and *F. sulcata*. There are slight, but evident differences in the foliage of these which do not differ much in size, except *F. sulcata*, which is the smallest of them. For general culture it is doubtful if a variety of species be desirable, as they are so much alike, but for adding a beauty of form to the garden of hardy plants in the early part of the year, there is nothing at all equal to them.—V.

Dates of Early-flowering Plants.—The dates on which the earliest flowers of a new year open their first blossoms have some interest to those who love their gardens. The singular absence of frost this year has caused winter flowers to come out betimes, as the following list of the very commonest hardy January flowers will show:

	1872-3.	1873-4	1874-5	1875-6	1876-7
Snowdrop ...	17 Jan.	25 Dec.	12 Jan.	not recorded	7 Jan.
Yellow Crocus ...	15 Feb.	18 Jan.	31 Jan.	2 Feb.	27 Jan.
Blue Crocus ...	15 Feb.	18 Jan.	11 Feb.	not recorded	26 Jan.
Winter Aconite ...	23 Jan.	6 Jan.	24 Jan.	19 Jan.	12 Jan.
Siberian Squill ...	4 March	3 Feb.	not recorded	2 Feb.	30 Jan.
Hepatica ...	not recorded	9 Jan.	26 Jan.	19 Jan.	12 Jan.
<i>Erica carnea</i> ...	29 Jan.	8 Jan.	12 Feb.	not recorded	25 Jan.

These dates are jotted down in my copy of Robinson's "Hardy Flowers." Not until writing this note have I put them together so as to compare them, and it is singular how they agree in the variation of the seasons. The winter of 1873-4 is much the earliest in the last five years, and in that season we spent the first fortnight of February in Scotland curling, which implies severe frost. Analogy may therefore induce us to look for a sharp bite yet ere winter lengthens into spring. The list might be made a very copious one from the notes on the margin of the book in question; but the above flowers are those with which we are most familiar.—SALMONCES.

NOTES OF THE WEEK.

ERANTHEMUM RETICULATUM.—This, one of the most valuable of ornamental stove plants, has leaves of an emerald green colour beautifully netted with gold. Well-grown examples of it may now be seen in Mr. Laing's nursery at Forest Hill, where, contrasted with other plants, they produce a good effect. This *Eranthemum*, indeed, is little inferior to *Croton pictum* in point of leaf beauty, and it possesses the good property of growing much more rapidly, and that in a much lower temperature.—S.

MIGNONETTE ON WALLS.—The common garden Mignonette is now flowering freely on the vertical face of a wall on which it is established in the Garden of Plants, Paris, and no doubt it is established in various similar positions elsewhere. In such a situation it becomes perennial, but the flowers are not so fine as when grown in rich ground.—V.

CLERODENDRON VISCOSUM IN WINTER.—This not showy species has a delicious odour, and, flowering freely at this season, would probably prove useful where many winter flowers are desired; it is firm and stubby in habit, and produces flowers freely—white with a stain of delicate pink in the centre. It is now in flower in the crowded stoves in the Garden of Plants, Paris, and probably it will prove more ornamental when well grown in a light house near the glass. It is an old plant, but not well known.—V.

MESSRS. VEITCH'S CAMELLIA-HOUSE.—This is now well worth a visit, hundreds of blooms being fully expanded, and many among them of new and choice varieties. They are arranged, too, in a way in which their colours are set off to the best advantage, and it may be added that, in order to realize the full beauty of Camellias, they require, as they have here, an extensive glass structure wholly devoted to them.—M.

EUPHORIA LITCHI IN FLOWER.—This plant, which produces the Lee Chee fruit now often seen in the London markets, is in flower in the Paris Garden of Plants, as they there suppose for the first time in Europe. The blossoms are green and small, like those of a Grape in long and branched panicles.—V.

BEGONIA FREBELI.—This is now finely in bloom in the Amburst nurseries. Its flower-spikes, which are very strong and numerous, each carry from ten to twelve large and brilliant scarlet blossoms. This *Begonia*, which is said to be quite hardy, is easily propagated, and will doubtless ere long be extensively grown for furnishing cut flowers for market, as well as for decorative purposes in other ways. Being bulbous-rooted, it may be started into growth and flowered at almost any season of the year.—C. S.

CROCUS FUSILLUS.—This modest little species is the only one now in blossom in the Paris Garden of Plants. The progress recently made in England with hardy plants is so great that Continental gardens are getting behind, though for collecting European species Continental gardens have greater facilities than ours.—V.

ODONTOGLOSSUM CIRRHOSUM.—Plants of this comparatively new and lovely Orchid are now flowering freely in Mr. Bull's nursery at Chelsea. Even in 60-sized pots small plants of it are producing from three to five flower-spikes, each of which bear from ten to twelve blooms. When well established, therefore, this species may be expected to prove one of the most floriferous of its class.—C.

FINELY-BLOOMED CŒLOGYNE CRISTATA.—A specimen of this useful winter-flowering Orchid in Mr. Wilkins' collection at Leyton is furnished with upwards of seventy spikes of bloom. Many of the flowers have been cut, but even now there are no fewer than 250 blossoms, fully expanded. Some of the spikes bear seven flowers each, five being the number generally produced. Few Orchids are more floriferous than this, or better adapted for supplying cut flowers for several weeks during the winter and early spring months.—S.

PITIOSPORUM TOBIRA AS A SMALL POT PLANT.—This fine shrub, hardy by the sea-shore in various parts of England and Wales, is grown in small pots for the Paris flower shops, in which it may be seen in bloom at this season. The plant is worthy of culture in this way in districts where it does not thrive out-of-doors, its blossoms resembling Orange blossoms in odour, and to some extent in appearance.—V.

TYDÆA BELZEBUTH.—Neat little plants of this *Tydæa* are now flowering freely in one of the plant-houses in Messrs. Rolliason nursery at Tooting. Its flowers, which are large and beautifully spotted, are very attractive, and contrast well with those of other plants now in bloom in the same establishment.—C.

BAMBUSA METAKE IN THE PARC MONCEAU.—The most effective plant now in this park is this fine hardy Bamboo, which forms huge tufts, the foliage on which is quite green. No evergreen shrub, Conifer, or other tree, is so striking. *Bambusa Metake* is quite hardy in the south of England, and in mild districts.—V.

THE INDOOR GARDEN.

NEW SPIRAL-LEAVED CROTON.

(C. TORTILE).

OF some new Crotons which are about to be distributed by Messrs. Veitch & Son, of Chelsea, during the ensuing spring, the annexed engraving represents one of the best. It has much larger foliage than that of *C. spirale*, and its colours are much more vivid, the ground colour being a bright glossy green blotched with golden yellow, the midrib and principal veins being of a rich carmine tint. As in most other kinds, however, the carmine here and there becomes mixed with the green, and this gives rise to various tints of brown or purple. This particular variety possesses an advantage over many others, inasmuch as its natural growth is so compact and bushy, that little or no artificial tying or training is required. Either as an exhibition plant, or for ordinary purposes of warm conservatory decoration, this plant assuredly deserves attention. Crotons of all kinds are readily propagated by means of cuttings made of the young lateral shoots; these root freely if inserted in a well drained cutting pot and plunged in a genial bottom-heat of from 75° to 80°. The best compost for Crotons is a matter of some importance. Fibrous loam, peat-mould, and peat, in equal proportions with a little coarse, well-washed sandstone grit, make an excellent compost for Crotons, and when they are well established, manurial stimulants can be added in the form of liquid manure; this is better than adding solid manure to the soil when potting. The chief points requiring attention in the culture of Crotons are ample heat, full exposure to light, and good ventilation; low, light, span-roofed houses suit them best, and if the glass be stippled with whiting—or, better still, a thin piece of tiffany be suspended an inch or two below the glass to intercept the direct rays of the sun, the leaves will become all the better coloured. One of the best cultivators of Crotons with whom I am acquainted plunges the pots in a bark bed when he starts his plants in spring, and thus treated

they grow most luxuriantly; he also turns them regularly round once or twice a week, so as to give every leaf an equal share of direct light. If the house in which Crotons, *Draecenas*, and similar plants are grown be well ventilated and kept moist, it is next to impossible to give them too much heat when growing, for it is useless to try to grow good Crotons under cool treatment. Occasional sponging is beneficial, and a sharp eye must be kept for thrips, scale, and mealy bug. The extreme variety observable in the leaves of Crotons deserves attention. The earliest form of leaf, as shown in *C. pictum*, is oblong lance-shaped, or Laurel-like; the next strikingly distinct leaf was that of *C. angustifolium*, a linear, drooping leaf, with a more or less undulating margin; then came narrow, lance-shaped leaves, with undulated edges, as in *C. undulatum*; and broad, smooth, Aucuba-like leaves, as in *C. maximum* and *C. Hookeri*. These were succeeded by interrupted linear foliage, as in *C. interruptum* and others; linear leaves twisted corkscrew fashion, as in *C. spirale*; and convo-

lute or ram's-horn-shaped, as in *C. volutum*; and the latest additions are varieties with long, broad, regular or irregular, strap-shaped leaves, or with the halberd-like or trilobed foliage. New varieties of Crotons are readily obtainable from seed, but as the male and female flowers are borne on different flower-spikes, it follows that cross-fertilization is necessary in order to secure seed. Any two good varieties may be crossed, and the result is sure to be interesting, but with the great variety now at command, cultivators generally will be satisfied with the sorts already in cultivation. B.

CYCLAMENS WITH SMALL FLOWERS.

WHILST agreeing with many of "M.'s" remarks (see p. 42) upon the culture of the Cyclamen, I must admit that I differ widely from him as to the cause which he assigns for the im-

perfect manner in which the plants mentioned at p. 3, vol. XI., have flowered. With respect to the maturation of the bulb, I fail to perceive much difference between "M.'s" practice and the old system once considered indispensable (but now quite discontinued) by those who grow Cyclamens extensively, viz., of drying off the bulbs after flowering. The exposure of the Cyclamen at any period of its existence to strong solar heat and an arid atmosphere appears to me to be subjecting it to a treatment quite foreign to its nature, and which I feel convinced is not at all necessary. That a certain amount of light and heat is indispensable for the proper development and ripening of vegetable tissue is undeniable, but the amount required is comparative, and varies according to the formation and natural habit of the plant. The amount of exposure to air and sunshine which is absolutely indispensable for some things would prove sudden death to others. It is the nature of some plants to mature and perfect themselves in almost perpetual shade, whilst others can endure but a very slight seclusion from the sun. With respect to the Cyclamen, the result of my own experience always tended to convince me that as soon as a plant has discontinued flowering, it should be removed to a cool situation, so that the fibre of the

Croton tortile.

root should never be allowed to perish, and the foliage be kept as green as possible. In shading, to preserve the beauty of the flowers, we do not necessarily deprive the plant of all sunshine; shade should not be applied before it is absolutely necessary, and removed directly the great glare of the sun is past. The plants in this way will obtain quite as much light and heat as is required to perfect the bulb. The removal to a cool, shady situation does not imply that they are to be completely secluded from the rays of the sun. If placed in frames on the north side of a wall or screen, for instance, they may receive a considerable amount of air and sunlight without being subjected to the fierce heat and drying air, which, I maintain, is not only unnecessary, but likely to prove injurious to them. "M." says that unless the bulbs are properly matured by exposure to sun, the flowers are not in them, and therefore cannot be brought out. Now, the plants in question are stated to be extremely well set with bloom; this fact would of itself be sufficient to prove that the bulbs had been sufficiently matured

and the plants fairly managed during the summer months; if, therefore, a test of maturation be the appearance or otherwise of bloom-buds, then in this particular case we must directly conclude that the plants have in this respect been properly treated, and will have received the required amount of air and light to perfect and ripen their growth. I am thus constrained to believe that the mischief lies in some error in treatment after the plants were set with bloom, or when placed in their winter quarters. "M." rightly observes that a stagnant atmosphere and a forcing heat produce injurious effects upon the Cyclamen; it is, in fact, one of those winter-flowering plants which, in garden phraseology, "will not stand driving."

Cyclamens may be had in bloom in November, December, and January with flowers quite equal in quality to those which come in the more favourable spring months. This is easily accomplished, but not by forcing; it is only by timely attention in the early summer months that this result can be achieved. If a plant be removed to a cool frame in April, and carefully attended to with water, so that the foliage does not perish, it will begin to form its bloom in July, and by the middle of August a one-year-old bulb will in all probability have a hundred well-developed flower-buds on it; if that plant be placed during September and the early part of October, where it can be thoroughly exposed to sun and air, never putting on the sashes unless the rains are very heavy, or the sun exceptionally hot, when a slight shade will even then be beneficial, it can be placed upon a shelf in a light airy house towards the latter end of October, where, with but a slight amount of artificial heat it will come well into bloom in December; and if, in other respects properly treated, there will be nothing to complain of with regard to the quality of the flowers. Plants may be had in ten or twelve months from the seed with some three or four dozen blooms on them, but it is only by giving them a free root-run and a moist, growing atmosphere that they can be so obtained. When, in their case, does maturation take place, for at the time when they should be maturing and ripening they are in a small growing condition? I prefer to mature and harden a Cyclamen in September, for by that time they should not be just starting, but should have their growth already perfected, and at that time much light and air are indispensable. I should be inclined to say that if "J. E.'s" Cyclamens (see p. 3) did not get sufficiently exposed to air and sunshine, it would rather be after having completed their growth in the autumn than before starting afresh into growth in the summer. As to exposing the corm itself, I have never found that that treatment exercised any beneficial effect upon the flower. I have tried them completely buried, partly covered, and with just the base on the soil, and have never found much difference in the amount or quality of the bloom produced. I prefer, however, to leave the corm half-way out of the soil, as it renders them less liable to damp, and at the same time admits of the production of fresh roots from the corm, which they will, if healthy, make during the flowering period, and which function, it is needless to say, materially aids them. In conclusion I will briefly summarize my treatment of bulbs one year and older:—In April they are placed in cold frames and shaded from the great heat of the sun, and sheltered from the heavy rains, drawing off the sashes early in the afternoon, and leaving them off all night and on dull days. This treatment is continued with slight variations during the summer months; in July they are looked through, shifted, or just shaken out and re-potted as they may seem to require it. As they begin to grow they are thinned out and placed where they can have plenty of room and air, and where they can, as mentioned previously, be thoroughly exposed in September. At this time, as they should have well-developed, luxuriant foliage, they must on no account lack moisture. The pots being pretty well filled with root, they will in dry weather require well attending to in this respect, and as the blooms are now in course of rapid development, insufficient moisture will alone suffice to produce undersized and deformed flowers.

Byfleet.

JOHN CORNHILL.

—As we happen to have a fine lot of healthy, well-flowered Cyclamens, and as the treatment which they have received seems different from that recommended by some of your correspondents,

and yet very simple, I may be allowed to describe it? We choose a border facing the north, and prepare it by mixing with the soil (common garden soil) some leaf-mould and sand, or road-scrappings; about the middle of May the bulbs (one and two-year-old ones) are shaken out of the pots and planted in that 9 in. apart. If the weather be very dry, a few waterings may be necessary; but they soon take care of themselves. Of 200 bulbs treated in this manner there was not one failure; all made strong, healthy plants. The only care during the summer was to keep them free from weeds, of which the road-scrappings gave us rather an abundant supply. The plants were taken up the first week in October, potted, and placed in a cold frame; afterwards they were removed to a cool greenhouse, in which they were ranged on a shelf close to the glass, and from time to time a dozen or so were removed and placed in a little heat. Under this treatment ever since Christmas there has been a fine display of large, well-developed flowers and foliage, all, indeed, that could be desired, and a promise of plenty more for some time to come.—J. M., *Wimslow.*

LATE-STRUCK POINSETTIAS.

Is it necessary that this plant should be arrested in the mid-season of its growth by treating it to a cold temperature, as I see it recommended by several growers, in order to flower it well or to keep it dwarf? Why not strike the cuttings late, keep them in small pots, and push them on with a genial stove temperature till they flower? This seems to me to be the best way to get good bracts and fine foliage, and the foliage is hardly less ornamental than the bracts, but it falls if the plant gets a check. All our Poinsettias were struck from July till October; none of them are in larger pots than 5-in., and those that struck first are between 2 ft. and 3 ft. high, the next in size and the smallest, which are in 4-in. and 3 in. pots, are only a few inches high; one I measured to-day was just 2 in. high, and had a good flower on it. I imagine that the natural habit of the plant is to make a rapid growth, and consequently fine foliage and then flowers, after which it goes partially to rest during the dry season, and this is the way it should be treated. There should be no potting from the time the cutting is struck till the plant flows.

Wintering Bedding Lobelias.—Complaints are often made as to the difficulty experienced in preserving stock of bedding Lobelias through the winter. Frost does them little mischief under glass, but damp kills them wholesale. The usual practice is to cut over a quantity of the old plants in autumn, then to lift them into pots and keep them on shelves in a cool house. Two causes of damping off are the roots not being established, and old wood being left in the plants that inevitably damps and decays. This can be corrected by having a quantity of plants kept in pots during the summer and trimmed over early, so that a renewed growth may be had ere the winter sets in. My own practice differs from that usually adopted, as I plant them out in a bed of soil in a cool house early in the winter, lifting plants that have been previously cut over, and that have already shown heads of good healthy foliage. These plants, instead of damping or developing attenuated foliage, throw out root-lets at every shoot, and now I could from my stock of *Blue Beauty* alone make 1000 well-rooted plants without taking a single cutting. Presently I shall prick them out thickly into frames, and they will make a stock of robust early blooming plants far more satisfactory than can be had from cuttings struck in heat. Any one having a cool-house may grow bedding Lobelias through the winter with success.—A. D.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Continuous Flowering of *Eucharis amazonica*.—This has been observed before, and I attribute it to the difference in the age of the bulbs, for I do not think that the same bulb flowers twice within a short period. Some of our plants which flowered in August and September are blooming freely again, but the flowers, so far as I can see, are produced from other bulbs, as when the plants were potted in spring, roots of various sizes were crammed into the same pot.—J. S. W.

Evil Effects of Pruning *Bougainvillea speciosa* in Winter.—Many fail to bloom this through cutting it back in winter like *B. glabra*. It should be borne in mind that *B. speciosa* blooms in March on wood of the previous year, whereas *B. glabra* flowers in terminal clusters on the young wood. It succeeds well in an intermediate temperature.—W. H. D.

***Cordylone vivipara* and *Russelia juncea* as Basket Plants.**—I can fully endorse all that has been said (see p. 61) as to the suitability of *C. vivipara* as a basket plant. It is much grown in rooms in Germany, as it withstands a dry atmosphere much better than most plants. I have also found *Russelia juncea* answer the same purpose perfectly. When well grown, these two plants contrast well with each other, the foliage and manner of growth of each being very distinct.—JOHN CORNHILL, *Byfleet.*

THE FRUIT GARDEN.

FRENCH MELONS AND THEIR CULTURE.

THE Melon of which the annexed is a representation seems to me to be one of the Cantaloup Prescott family—possibly Hâtif à Châssis, or Fond Blanc de Paris. "Each is good, but both are best." All the Cantaloup Melons resemble each other, but vary greatly under different kinds of treatment. Mostly every gardener in France, as here, owns a variety of Melon, and their flavour depends entirely on the time when the fruits are removed from the plant—not too soon before they are ripe, and not too late after they are ripe. French gardeners never leave a Melon to ripen on the plant. Half an hour's sun after they begin to have a ripe smell ruins the flavour of a Melon, and hence they are cut just before they begin to smell ripe; and only experienced cultivators know when to gather them at the right time. There is no doubt that in this country Melons are left too long on the vines after being ripe, and hence their occasionally bad flavour. In fruit shops, too,

Cantaloup Melon of the Paris Markets.

they are exposed in windows, and their flavour is destroyed in a short time. My opinion is that the Cantaloup Prescott is a fine Melon when well grown and gathered at the proper time. It is remarkably refreshing without being too sweet and sickening, as some of the varieties in this country are.

Floors Castle, Kelso.

H. KNIGHT.

LATE GRAPES.

MR. WILDSMITH (see. p. 45) says "that so much has been said and written about Grapes and Grape-growing, that it is difficult to say or write anything new upon the subject." This is no doubt true, and yet, strange to say, Grape-growers are still far from being agreed as regards many matters connected with Vine culture. For example, the advantage or otherwise of inside borders, the desirability of supplying heat to the roots, and where this is deemed necessary how best to accomplish it, are still matters on which opinions differ. At present, however, I merely wish to inquire as to what varieties of Grapes growers generally consider the best for furnishing a late supply of fruit, and with the view of aiding the matter I will give the names of a few of the sorts which I consider to be the best for this purpose, placing them in accordance with their order of merit. I have therefore no hesitation in placing Lady Downes Seedling first upon my list, and I am pleased to see that my opinion in this instance is in accordance with that of Mr. Wildsmith. Taking all points into consideration, there can be little doubt that this variety ranks first among late Grapes. This would not, however, be the case if Mrs. Pince's Black Muscat could be induced at all times to colour properly, as when it does this, and even sometimes when it does not quite attain the desired colour, its quality is superior to that of Lady Downes or to that of any other late black Grape, except the Muscat Hamburg, which is perhaps the finest flavoured of all black Grapes. This variety, however, cannot be recommended as a late keeper. I am inclined to attribute the want of colour in Mrs. Pince in many cases to overcropping, and I believe in the majority of instances

it will be found that if a healthy plant of this variety be allowed to carry only about two-thirds of the weight of fruit which an equally healthy plant of the Lady Downes or Alicante varieties would ripen and colour to perfection, it will generally be found that under these conditions the fruit of Mrs. Pince will attain a colour equal to that of either of the other sorts named. It has been thought by some that Mrs. Pince requires a somewhat higher temperature than is usually given to such sorts as the Alicante and other late varieties. This may be the case, but as far as my experience goes in the matter, I have found it ripen and colour as well as could be desired in the same house as the Alicante and Lady Downes, and where very little fire-heat had at any time been applied. As has been stated, I place Lady Downes first upon my list of late or long-keeping Grapes, Mrs. Pince's Black Muscat second, the Black Alicante third, and West's St. Peter fourth. There are, I believe, no varieties of white Grapes which, for late-keeping properties, are equal to the black kinds, although for this purpose such sorts as the Raisin de Calabre and Trebbiano have been recommended. These, however, seldom keep so well as the Muscat of Alexandria, which Mr. Wildsmith says will keep with care if well ripened to the end of March or April. This I must admit I have never been able to accomplish; indeed I feel thankful when Muscats keep in good condition until the end of January, and this they usually do. P. GRIEVE.

Culford Hall, Bury St. Edmunds.

STRAWBERRY CULTURE IN THE MIDLAND COUNTIES.

MUCH difference of opinion exists among cultivators as to which is the best system of growing Strawberries. Some contend that it is best to plant in deeply-dug and heavily-manured soils, while others advocate shallow soils with a liberal supply of manure. Some cultivators, moreover, contend that it is best to destroy the old beds and make fresh ones every year; others plant in autumn, and pinch off any flowers which may appear the following season, with the idea that plants thus treated will gain extra strength, and make up for the loss of one season's crop. A strong clayey loam suits Strawberries better than light land, and in such soils they will prosper for a number of years without exhibiting signs of debility. All runners should be cut away as they appear, and a top-dressing of rotten manure should be given them during the winter. The first point is the preparation of the soil; if this be not properly attended to no after management will give satisfactory results. The digging or trenching of the ground should, if possible, be done late in the autumn or early in spring, and should not be put off, as is sometimes done, until new plantations are about to be formed. Select the ground intended for the crop early in winter. We have three plantations, and we make one bed and destroy one (the oldest) each season. Immediately a bed is destroyed, the ground thus made vacant is immediately dug and sown with Turnips which are cleared away soon after Christmas, and the ground is then prepared for the next Strawberry crop; but previously to the Strawberries being planted the ground will have produced a heavy crop of Potatoes. These are cleared off early in August. The same process is gone through each year, and thus a year elapses from the time of destroying one plantation and planting another on the same ground, and in the meantime we take two other crops from the ground, which with the manure that is applied brings it into good condition for the Strawberries. The reason for occupying the same ground is that we do not wish to use it any more than we can possibly help for culinary crops. When the weather is tolerably dry we trench the ground two spits deep, but do not choose very frosty weather for the operation, as it is a bad practice to bury frozen earth. When it is desirable to plant a new crop of Strawberries immediately the ground has been cleared of the old one, it is a good plan to work in a quantity of fresh soil while trenching. We trench the ground as follows:—Take out a trench 2 ft. wide and two spades deep at one end of the quarter, and the soil taken out is wheeled to the opposite end to fill up the last trench. We then measure the width of another trench and mark it off with the spade. The top spit is then thrown into the bottom of the trench, and the bottom spit of the second

trench is put on to the top spit, thrown into the first trench, and so on to the end. By this process a portion of fresh soil is brought to the surface in the place of that exhausted by the previous crop. When the trench is open we place at the bottom 6 in. or 8 in. in thickness of fresh stable manure, and when the first spit of the next trench is thrown on to it we introduce another good layer of manure, placing the coarse material at the bottom and the decomposed nearer the surface. The rough manure becomes decayed before the roots get down to it. Having finished the trenching, the surface is left as rough as possible, in order to expose it to the pulverizing and fertilizing influences of the weather until the following spring.

The ground having been properly prepared, the young plants, consisting of well-rooted runners, may be put out. In the selection of runners, care should be taken to choose only those that are stout and healthy, with a good plump bud in the centre, and they must be from vigorous fruiting plants. This is better than taking plants at random, and will invariably give more satisfactory results. In order to have the runners established as soon as possible, they should be layered in small pots, filled with rich loamy soil and a little rotten manure. They will make rapid progress in this rich compost, and as soon as they are fairly rooted, which will be in two or three weeks, if never allowed to become dry, they may be severed from the parent plants, and planted in their permanent quarters. They must not, under any circumstances, be allowed to remain in the pots until they become pot-bound; if the ground be not ready for them they had better be shifted into pots a size larger, rather than they should receive any check in that way. The planting must be done with great care; if the soil be light it must be made firm. Some, after digging and preparing the beds, tread or roll them previous to planting, as if for Onions; but, if the ground be tolerably stiff, this treading and rolling will be unnecessary. In planting, the soil must be made firm about the roots. The method of planting which we practise, unless we wish to plant so many rows on a limited piece of ground, is to plant them in double rows 2 ft. apart, and every alternate row 2½ ft. from each other. Thus treated a little more space is left between every other row to walk on without treading on the fruit. We place each plant 2 ft. asunder in the rows in half quincunx order. The style of planting is quite a matter of fancy, but whatever plan may be adopted the plants must have plenty of space in the rows. Some cultivators, anxious to make the most of their ground, plant at 1 ft. apart in the rows, and after the first crop remove every alternate plant. This, no doubt, is a quick and profitable mode of culture. Others I have known to take a crop of Cauliflowers off the ground, and when it was quite hard to scoop out some hollow spaces 1 ft. in diameter and pour into each 3 or 4 gallons of liquid manure from the cesspool. The next day the ground has been levelled, and in each soaked place three plants have been planted. Strawberries thus treated have grown away freely, and the next year produced an excellent crop of fine fruit. On the approach of winter we mulch the beds all over with short rotten manure about 2 in. thick. The manure is first put down in little heaps, and then the beds are gone over, holding the leaves of the plant in one hand and spreading the manure round them with the other. This is allowed to remain until spring—say about the first or second week in April—when it is knocked about with a Dutch hoe and the straw raked off, leaving that which is most rotten. The manure must not be allowed to remain packed round the crowns; on the contrary, the rows must be gone over, and the stools cleared and left free. Keep the plants free from runners and the ground free from weeds; it is also important, when the plants are in bloom, to give them a good supply of manure-water. As soon as the plants are in bloom, some protecting material should be placed beneath the trusses to prevent the fruit from being injured by heavy rain; some use clean straw, others litter from the stable, and some who cannot obtain either use Grass mowings. Fine fruit may be expected the first year after planting; the crop may be a little the heaviest the second year, but we obtain the finest berries the first season. One other question remains to be discussed. Is it right to dig between the plants? On this point I say "Doubt."

As regards varieties, the best method to adopt is to ascertain what kinds suit the soil which one has to cultivate, and this being accomplished, discard the sorts that are unsuitable. Eclipse is a most prolific, large-fruited variety. Sir J. Paxton is also a fine variety; it is of a rich glossy colour, sometimes cone-shaped and sometimes cockcomb. Dr. Hogg is much finer than the old British Queen, from which it was raised, and is one of the best Strawberries grown. Vicomtesse Héricart de Thury deserves all that has been said in its favour; it is very hardy, a most abundant bearer, and succeeds well on most soils. James Veitch is of more recent introduction; it produces fruit of exquisite beauty, colour bright vermilion, with a pleasant Apricot flavour. Duke of Edinburgh promises to be very good, fruit of average size, possessing a most delicate perfume. The above are what we grow, and for heavy cropping Eclipse and Vicomtesse Héricart de Thury are perhaps the best. R.

The Setting of Muscat Grapes.—Many complaints are often heard with respect to the difficulties now attending the perfect setting of this the queen of Grapes, and many ways and means have from time to time been suggested to accomplish this much-desired object. Many resort to syringing the bunches when in flower; others believe in the slamming of doors and sashes, and shaking the Vines; but probably there is no method so simple and effectual as drawing the hand gently down the bunches when in full flower. The hand should first be covered with pollen from free-setting kinds, such as Hamburga, Alicante, &c., and if this be done a few days in succession, it is probable that almost every berry will become properly fructified, swell rapidly and evenly, and ripen well.—S.

Raising Nut Trees.—The best method of keeping Nuts for seed is to let them get quite ripe before gathering; then partly dry them and mix them in dry sand, put them in thick, mouse-proof boxes, and bury them in sand on a dry bank. In spring select a rich, loamy soil well pulverized, and drill in the Nuts far enough apart to allow the trees some space to grow and room to cultivate between the rows. As soon as the young plants appear the soil should be loosened around them frequently, which will effectually prevent weeds from growing, as well as hasten the growth of the plants. After the second year's growth, according to the "Home Journal," it might be well to clip off the ends of the vigorous side branches, thus sending the vigour of the tree into the main stem. Do not transplant them until they are large enough to be staked, or until they are three or four years old. The ground, if intended for an orchard, should be subsoiled, and the holes for the young trees dug deeply and fertilized with a little old manure, unless the soil is very rich. After the first year's growth, in order to make handsome and fruitful trees, it is necessary to use the knife freely.—"Home Journal."

Apple Stocks.—What is the difference between Crab, Paradise, and Doucin Apple stocks?—C. [Wild English Crab stocks are seedlings obtained either by sowing pips of fruit gathered from the hedges and woods, or by hillock layering. This kind of stock is that best suited for standard or orchard trees. The Paradise stock is a low-growing Apple, wild in Russia and the Caucasus, and its merits as a stock for bush or pyramidal trees consist in its short, fibrous, wig-like roots, and in its finely-grained and slender stem; hence it exerts a restrictive influence, and induces fertility at a much earlier date after grafting than either the Crab or Wild Apple stock. The Doucin is a variety of Apple long grown in France and Belgium, and, like the Paradise, it has a restrictive influence on the growth of the scion; its use as a stock, however, is mainly due to its easy propagation either by means of cuttings or layers.]

Fruit Trees Branching Low.—Let fruit trees branch low. Why go aloft when one can pluck as good fruit "off a step ladder?" Secondly, in low-headed trees the stem is shaded from the hot sun, the surface soil is maintained cool and moist, and the pruning can be kept better in hand; lastly, the recent vigorous wind-storm fully demonstrated that the fruit is not so likely to get blown off. But, says some one, "How can I pasture my orchard?" That explains the whole objection to this system; some cultivators begrudge the ground their trees stand on; they want to make their orchard carry double—a good crop of Grass and another of Apples. Try one, says an American paper, and pay attention to it, and see what returns are obtained at the end of the season.

Forking among Strawberries.—Will Mr. Baines tell an old Strawberry grower how (as recommended, see p. 76) he is to fork his beds over a few inches deep without disturbing the roots? This information is scarcely orthodox. That veteran Strawberry grower, Mr. Myatt, would shake his head and whisper "won't do."—R. S. C.

THE FLOWER GARDEN.

THE HONEYSUCKLES OR WOODBINES.

By GEORGE GORDON, Author of "The Pinetum."

Most botanists consider the Caprifoliums as only a section of the genus *Lonicera*, but they are easily distinguished by their climbing habit of growth, and in the berries being solitary and three-celled while young, but when matured usually one-celled. The Honeysuckles are free bloomers, mostly very fragrant, some evergreen, and nearly all hardy; they thrive freely in any good garden soil, and form beautiful objects for training over arbours or against posts or walls, and flower freely during the summer and autumn months; the leaves are mostly ovate-pointed, opposite, entire, sometimes connate towards the ends of the shoots; the flowers are long, tubular, ringent, mostly disposed in terminal whorls, and generally very fragrant. They are robust climbers, and are natives either of Europe, Asia, or America.

Common Woodbine (*Caprifolium Periclymenum*).—The Common Woodbine or Honeysuckle is a native of the middle of Europe, growing in hedges, groves, and thickets, and is found in quantities in Britain and similar situations. The leaves are deciduous, ovate-obtuse, tapering to the base, with the upper surface bright green and smooth, but they are sometimes downy when young and glaucous

Late-flowering Dutch Honeysuckle (*C. P. floribundum*).

beneath; the flowers are in terminal clusters, long, tubular, and externally deep red or rich yellow, and produced from June to August: berries nearly globular, red, and accompanied by permanent bracts. There are three or four distinct forms of this kind, one, the Late-flowered (*serotinum*), has smooth-branched and reddish flowers, which are produced later in the season than the ordinary form; it is known in gardens as *C. P. floribundum* or the Late-flowering Dutch Honeysuckle, and produces a greater number of flowers in each cluster than any of the other varieties.

Dutch Honeysuckle (*C. P. helgicum*).—This has the lower leaves somewhat cordate, and the upper ones connate; they are oblong-ovate, of a bright green above, but pallid and glaucous beneath, and on longish foot-stalks; the branches are of a violet colour with a glaucous bloom. It is a native of Corsica, the south of France, and Italy; the flowers are large, cream-coloured, and mostly in heads of six, and very fragrant. It is generally known in collections as the Dutch Honeysuckle, and may be trained to a single stem and formed into a bush, which in the wild sort cannot, the branches being too weak and trailing for the purpose.

Oak-leaved Honeysuckle (*C. P. quercifolium*).—This variety has the leaves sinuated like those of the Oak, and of which there is a form with the leaves marked near the margin with yellow. It is found in England and Germany.

Goat's-foot Honeysuckle (*C. perfoliatum*).—This kind forms a fine, robust climber, with deciduous, obovate, acutish-glaucous leaves, the uppermost ones being broad, and the lower ones distinct and somewhat stalked; while two or three of the upper pairs are united, and form a concave cup just below the flower-heads. The flowers are disposed in one or more axillary, capitate whorls 2 in. long, yellowish, with a bluish-coloured tube, and very fragrant. The berries are elliptical and of a tawny or orange colour, and ripe in September. It is a native of the south of Europe, in woods, hedges, and thickets, and also of Britain in like situations, but particularly

Belgian variety of Dutch Honeysuckle (*C. P. belgicum*).

in chalky districts. It flowers in May and June. It is the *Lonicera Caprifolium* of old writers, and is frequently confounded with the Common Woodbine in collections.

Italian Honeysuckle (*C. etruscum*).—The leaves of this species are deciduous, obovate, obtuse, and pubescent; the lower ones are on short petioles, the upper ones connately-perfoliate, acute, and glabrous. The flowers are disposed in verticillate heads, with usually about three heads on the top of each branch, glabrous, sweet-scented, purplish outside as they expand, and yellowish-white inside, but finally change to yellow before they wither. It is a native of the south of France, Sicily, and Dalmatia, on hills, and flowers in May and June.

Minorca Honeysuckle (*C. implexum*).—This is quite a glabrous species with evergreen, glaucescent leaves, the lower ones being oblong and distant, the uppermost ones connate, and forming a hollow, roundish cup. The flowers are disposed in capitate whorls, long, tubular, and ringent, and are produced from July to September. It is a native of the Balearic Islands and Sicily. The flowers are purplish before expansion, but becoming paler on the outside as they expand and whitish inside, finally changing to a yellow before they fade.

Yellow-flowered Honeysuckle (*C. flavum*).—This species is quite glabrous with rather large, ovate leaves, sometimes glaucous beneath, the upper ones are connately-perfoliate and frequently cup-shaped; the flowers are large in terminal verticillate heads, rather ringent with oblong-obtusate lobes, very fragrant, and bright yellow when first they appear, but as they fade become orange-coloured. It is a native of South Carolina and New York, and blooms in June and July. This kind is frequently named *C. Fraseri* in collections.

Downy-leaved Honeysuckle (*C. pubescens*).—The leaves are deciduous, broad, ovate-elliptic, on short foot-stalks, pubescent, and ciliated on the margins, glaucous beneath, with the upper ones connately-perfoliate; the flowers are disposed in racemes, composed of verticillate heads, and the corollas beset with glandular pubescence, and of a yellow colour. It is a native of Vermont, Massachusetts, New York, and Canada. This is the *Caprifolium Goldii* and glaucum of some writers, and is considered by Dr. Torrey as only a variety of *C. flavum*, but it is much harder than that kind.

Douglas Honeysuckle (*C. Douglasi*).—The leaves of this handsome species are from 4 in. to 6 in. long, deciduous and deep green on the upper surface; they are oval, acute at both ends, stalked, glabrous, ciliated on the margins, tomentose on the outside, with the upper ones connate; the flowers are disposed in capitate whorls, two-lipped, deep orange red and scentless; the corollas are pubescent. It is a native of the western coast of North America, and flowers in July and August.

CAPRIFOLIUM CILIOSUM is considered as only a variety of this species, with yellowish flowers, and a less robust habit of growth.

Small-flowered Honeysuckle (*C. parviflorum*).—The leaves of this kind are elliptic and sessile, the lower ones somewhat connate, the upper ones connately-perfoliate, glabrous, and very glaucous beneath; the flowers are yellow, very small, and disposed in verticillate heads; the corollas are glabrous, with the tube gibbous at the base on one side. It is a native of North America, from New England to Carolina, and frequent in Canada; also from the Hudson's Bay to the Rocky Mountains, and flowers in June and July. In the Canada plant the flowers vary in colour, and the leaves are more or less downy. Most botanists consider it as only a variety of *C. Douglasi*, but it is easily distinguished by its short flowers.

[Synonyms—*C. bracteosum*, *C. glaucum*.]

Western Honeysuckle (*C. occidentale*).—The leaves are deciduous, oval, almost sessile, glabrous, ciliated on the margins and glaucous beneath; the upper ones are connately-perfoliate and rather large; the flowers are disposed in verticillate heads, and longer than any other of the North American species; the corollas are of a deep orange-red, glabrous, with an elongated tube, which is gibbous above the base and the divisions nearly equal. It is a native about Fort Vancouver, on the Columbine, and flowers in June and July.

CAPRIFOLIUM CILIOSUM appears to be a form of this kind, with the leaves somewhat more downy and distinctly ciliated on the edges. This will be found a very handsome plant for training against a wall.

Evergreen Trumpet Honeysuckle (*C. sempervirens*).—This species has sub-evergreen, obovate or ovate leaves, glaucous beneath, deep green above, and quite smooth; the upper leaves are connately perfoliate, about 2 in. long and 1 in. broad; branches brown and rather slender; the flowers are nearly naked at the top of the branches, and in whorls; the tube of the corolla is ventricose on the

Evergreen Trumpet Honeysuckle (*Caprifolium sempervirens*).

upper side, and of a beautiful scarlet colour outside, yellow inside, 1 in. long, and scentless; fruit reddish-yellow, and ripe in September. It is a native of North America, from New York to Carolina, in stony dry woods, and flowers from May to August. There are three varieties of this kind, viz., *C. s. major*, with roundish leaves and larger flowers; *C. s. minor*, with oblong leaves, acute at both ends, and much smaller flowers; and *C. s. Browni*, which has larger flowers of a brighter colour than those of the species, the latter a seedling variety raised several years ago by the late Mr. Charles Brown, of the Slough Nursery.

Evergreen Honeysuckle (*C. gratum*).—This is a vigorous-growing kind, with a woody stem and sub-evergreen leaves, which are obovate and glaucous beneath; they are reticulately veined and glabrous; the upper ones are connately perfoliate and the branches reddish-brown; the flowers are disposed in approximate whorls, the corollas are ringent, reddish inclining to scarlet outside and yellow inside; the berries are red and ripe in September. It is a native of North America, from Carolina to New York on the mountains,

rambling among rocks in shady, moist situations, and produces its flowers from June to September.

Tubular-flowered Honeysuckle (*C. tubulosum*).—The leaves of the Mexican Honeysuckle are evergreen, oval-oblong, obtuse at the ends, roundish at the base, and with the upper ones connately-perfoliate; the flowers are in close, verticillate, globular, terminal heads, and 1½ in. long, with an ample tube; the corollas are gibbous at the base, with equally divided lobes, and of an orange-scarlet colour. This kind has the habit of the scarlet Trumpet Honeysuckle, and is a native of Mexico, flowering in May and June. It is too tender for the open air, and requires to be grown in the greenhouse, where it forms a very pleasing object.

Bristly-leaved Honeysuckle (*C. hispidentum*).—This is a small, slender-growing plant, with small, cordate-ovate leaves, which are obtuse and glaucous beneath, sessile towards the ends of the shoots, and hispidly-pilose. The flowers are small, rose-coloured, scentless, and in pedunculate umbels; the corolla is smooth, two-lipped, which is longer than the tube. It is rather prostrate, from 2 ft. to 3 ft high, found on the north-west coast of America growing in woods, and flowering in July and August. This plant thrives best when planted in peat.

Kinds with Axillary Flowers in Pairs.

Chinese Honeysuckle (*C. confusum*).—The leaves are ovate, acute, rounded at the base, downy on both surfaces, as well as on the foot-stalks; the peduncles are axillary, two-flowered, longer than the foot-stalks, and disposed in something like a Thyrea at the tops of the branches; the segments are ovate and, as well as corollas, pubescent. The flowers are in axillary pairs, 1 in. long, two-lipped, and very profuse; they are whitish at first, but gradually change to a golden yellow colour; and hence it is called by the Japanese *Sin-Kadsura* and *Kinginka*, that is, the Gold and Silver flowered: it is a native of China and Japan, and flowers in July.

[Synonyms—*Nintooa confusa*, *Caprifolium japonicum*; Chinese names, *Nintoo* and *Sin-too*.]

Japan Honeysuckle (*C. japonicum*).—This kind forms a robust climber, with twining, flexuose, very hairy, opposite branches, bearing two leaves and two sessile flowers at the top of each. The leaves are ovate, acute, villose, pale beneath, and about 1 in. long, with the uppermost ones the smallest; the corolla is tubular, 1 in. long, red, white inside, villose on the outside, and very fragrant: it is a native of China and Japan, and flowers profusely from July to September.

[Synonyms—*C. flexuosum*, *Lonicera chinensis*, and *Nintooa japonica*.]

Long-flowered Honeysuckle (*C. longiflorum*).—This is a robust, twining plant, glabrous in every part; the leaves are oblong-lanceolate, shining above, pale beneath, on foot-stalks, and deciduous; petioles short, two-flowered, and about the length of the foot-stalks; the corollas are tubular, very long, filiform, and two-lipped; the flowers are at first snow-white, but finally change to a golden yellow colour: it is a native of China and Nepal, and flowers from July to September. It is tender, and requires the protection of a pit or to be kept in the greenhouse.

[Synonyms—*Nintooa longifolia*, *Caprifolium longifolium*, and *C. nepalense*.]

Short Flower-stalked Honeysuckle (*C. brachypodum*).—The branches of this kind are slender, flexuose, and very villose at the apex; the leaves of the variegated form are small, ovate-oblong, acute, glabrous, on short and villose foot-stalks, the upper ones the smallest, they are beautifully netted on the upper side with golden veins, and about 1 in. long; the flowers are few, almost sessile and axillary; the berries are distinct, globose, glabrous, pointed and black when ripe. It is a native of Japan, and flowers in June and July. This kind forms a slender climber or sub-prostrate plant, 3 ft. or 4 ft. high, and is the *Lonicera flexuosa* of Thunberg. It is very different from the one originally distributed by Dr. Siebold under the name of *C. brachypodum*, which bears a considerable resemblance to the *C. japonicum* (the *C. flexuosum* of Lindley and Leddiges). It has also been named *Lonicera nigra* by Thunberg, but is a very distinct kind from *L. nigra* of Linnæus, which is a European plant, with twin flowers and berries joined together at the sides. The variegated form is the *L. aureo-reticulata* of the nurseries.

Lonicera fragrantissima in Ireland.—In the neighbourhood of Dublin this sweet-scented Honeysuckle begins to flower on walls early in December, and continues a long time in blossom. Its period of flowering is greatly lengthened by skilful pruning, a kind of attention which it well repays.—*C. M. D.*

NEW HOLLYHOCKS.

THE production of new Hollyhocks in the south of England is now almost entirely confined to Mr. Chater, of Saffron Walden, whose seedlings are yearly looked forward to with much interest. The following are his new varieties for the coming spring, and as far as they have been seen in public they fully deserve all that has been said in their favour. First on the list is Achievement, an exceedingly pretty and distinct flower, the ground colour of which is rosy-red flushed in the centre with buff; it is of good size, full, and quite free from pockets. Crimson Queen is a fine deep hue of shaded crimson, and is considered by the raiser to be the darkest of all the crimson shades yet offered; it is large, full, symmetrical, and very attractive. It may be interesting to know that this variety forms a grand spike of flowers for show purposes. Her Majesty, a very large and bold flower of a bright rosy-red colour, also produces a fine spike, and its habit of growth is all that can be desired. Le Grand, a very fine flower, was offered in Mr. Chater's catalogue last year, but he was unable to supply it owing to insufficiency of stock. It is pale flesh-coloured with a salmon centre. This is probably one of the finest Hollyhocks yet raised. Vesuvius, glowing reddish-crimson, is considered by Mr. Chater to be the finest flower of its class, being excellent in form and striking in colour. Lastly comes Virgin Queen, a fine, bold, pure white-flowered variety, good in quality, and one which forms a long and noble spike. This, perhaps the best white Hollyhock yet raised, was awarded a first-class certificate at South Kensington in 1876.

The following is a selection of thirty-six fine Hollyhocks, well varied as regards colour and, generally of good habit of growth, viz., alba superba, pure white; Alfred Chater, mottled rose, flushed with carmine; Black Gem, glossy blackish-maroon; Competitor, deep rich purple; Conquest, deep crimson, very effective; Eclipse, bright rosy-red; Edward Speed, French white, suffused with deep purple; Eleanor, soft pale rose; Emperor, crimson-maroon; Enchantress, creamy-white, with a rosy-purple centre; exultum, rich shining maroon; Fascination, rosy-lilac, edged with silver; Fire King, bright glowing, reddish-crimson; Fred. Chater, pale yellow; Golden Drop, the deepest and brightest yellow, forms a remarkably fine spike; James Allan, beautiful bright plum; Jessie Dean, clear apricot, sometimes tinted with salmon; Joshua Clarke, brilliant cherry; Junia, pale primrose, suffused with purple, distinct and good; Leviathan, bright reddish rose; Lord Napier, deep glowing scarlet-crimson; Midnight, deep glossy maroon, very striking; Mrs. W. Chater, pale flesh, deeper in tint in the centre; Nonpareil, rich dark reddish maroon-purple; Nymph, white with purple base; Orange Boven, clear deep apricot; Perfection, delicate silvery flesh, a grand variety; President, yellowish but heavily suffused and edged with rose; Rose d'Amour, beautiful rosy-peach, an excellent flower; Ruby Queen, deep shining ruby; Triumph, very dark crimson; Tyrian Prince, rich crimson-purple; Victor, bright rosy-red; Walden King, bright scarlet, rich and striking in colour; Walden Queen, beautiful soft delicate flesh, flushed with rosy carmine; and Walden Primrose, clear, pale primrose.

The ravages committed by the Hollyhock disease deters many from attempting its culture, and it must be admitted that it is a sad sight to see a group of plants stricken with this fungus; it fastens on the leaves and robs them of all vitality, giving them quite a scorched appearance. In times of drought the disease appears to be more deadly in its operation than during moist weather, and this suggested to Mr. Chater that he should endeavour, by a careful system of culture, to make the plants as disease-resisting as possible. It has been the custom to plant out Hollyhocks in well-manured ground in April and May, planting on the ground-level. Now, Mr. Chater has large trenches dug out early in autumn in the form of Celery trenches, but broader and deeper, forking up the bottom, and mixing into the trench a good dressing of manure as the work proceeds. The soil thrown up roughly is acted upon by the frosts of winter, which pulverize it. When the season comes round for planting, the bottom of the trench is again forked over and the sides turned in, and then planted. By this method the Hollyhocks were kept moist and cool about the roots; they made good growth, and were robust and vigorous by the time drought set in. By means of the trench water could be given without fear of its running away, as is sometimes the case when the surface is hard and unbroken. Last season was the first time Mr. Chater employed the trench method, but the results were highly satisfactory; and he hopes, by perseverance and planting tholy in such trenches in exposed situations and by the employment of suitable mulching, to mitigate the effects of the disease.

Quo.

Mimulus moschatus Harrisoni.—This plant is a hybrid, obtained by Messrs. Harrison & Sons, of Leicester, who have ex-

hibited it at the principal floral exhibitions during the past year, and that it is a most valuable ornamental plant is in some measure attested by its having received first-class certificates from the Royal Horticultural and Royal Botanical Societies. The plant is a hybrid between the large-flowered Musk of our cottage windows and the spotted form of *Mimulus luteus*, known in gardens as *M. maculatus*; and when I say that it has the delicately-fragrant leaves of the first parent and the large showy flowers of the spotted *Mimulus*, some idea may be formed of its value as a plant for conservatory decoration, or even for the embellishment of the window garden, a fact which will render it peculiarly valuable to plant growers for market, as well as to amateurs and villa gardeners who grow their own flowers. As delicately perfumed as the Musk plant, it far exceeds it in its flowers, and possesses the additional merit of being more permanent, since strong roots can be forced at all seasons, and even during the winter months, when its fragrance recalls the days of early summer. Its culture is as easy as that of the common Musk plant of the cottager's window, and, considering its other points of excellence, it does not seem improbable that this variety will entirely supersede the other kinds when it becomes better known.—B.

Hybrid Pentstemons and their Origin.—"Quo" (see p. 69) attributes the origin of our hybrid Pentstemons, now so numerous and so lovely, to "careful seeding from such attractive species as *P. gentianoides*, *P. Cobæa*, and others, but these two mainly." That the so-called *P. gentianoides* (correctly speaking, *P. Hartwegi*) is the parent type no one will deny, and possibly *P. atropurpureus* and *P. atro-cærulescens* may have had some influence on the variations; but seeing that *Pentstemon Cobæa* had absolutely disappeared from cultivation before a single garden hybrid of this type was produced (the first and last plant I saw of the true species *P. Cobæa* was in the year 1844), it appears somewhat singular to associate its name with the origin of a plant, the earliest of whose variations date some eight or nine years subsequently. Undoubtedly the two species which I have just named had some influence in, as it were, breaking the specific type of *Hartwegi's* original plant; and the many variations are, in my opinion, to be attributed to careful seeding and judicious selection rather than to any direct and continued hybrid influence. I have tried for years to cross *P. Hartwegi* with *P. digitalis*—a species which belongs to the same section as *P. Cobæa*—but without the slightest result.—JAMES C. NIVEN, *Botanic Garden, Hull*.

Hybrid Echeverias.—Echeverias rank amongst the most popular of all succulent plants, being extensively used for edging the carpet beds and ribbon borders now so fashionable in public and even in private gardens. Some of the choicest species well deserve a place in every greenhouse, and among these *E. metallica*, *Peacocki*, *farinosa*, and *pulverulenta* may be named as distinct and handsome kinds. The two last are Californian species, their foliage being densely covered with white powder, which gives them a distinct character; and as this delicate covering enhances their beauty, care must be taken not to remove it by touching the leaves, or allowing water to fall upon them. *E. agavoides* is also a robust and desirable plant for pot culture. Two or three species have been separated under the generic name *Pachyphyllum*, but their consanguinity having been proved by the hybridiser, they may now be included in the genus *Echeveria*. Within the last year or two, Continental nurserymen have raised numerous beautiful hybrids, some of which, such as *E. imbricata*, *ovata*, *glauco-metallica*, *scaphylla*, *retusa-glaucia*, and *floribunda splendens*, are a great gain to our gardens.—F. W. B.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Drought-resisting Viola.—Has "T. S." (see p. 60) ever grown *Viola Blue Bell*? I venture to think that he would find this kind withstand any reasonable amount of drought. I have grown it for three seasons past, and have not yet known it to fail flowering continuously from March to November, notwithstanding that ours is naturally a dry, hot soil.—W. W. H.

Failure in Alternantheras.—It is said that we report our successes, but seldom our failures. I therefore make a beginning by saying that I have lost all my *Alternantheras*, and that I shall feel grateful to any kind friend who will send me some.—R. GILBERT, *Burghley*.

Early Primroses.—After reading Mr. Gilbert's note (see p. 60) respecting Dean's Primroses, I went to examine some plants that I had from the same source, and which are growing on a north border, when much to my astonishment I found two varieties in bloom and others throwing up their flowers. I can fully endorse Mr. Gilbert's recommendation of these Primroses, which are in every respect excellent.—W. W. H.

Cocoa-nut Fibre and its Uses.—This is largely used in market gardens situated near factories, where it can be got cheaply. It is usually spread on the surface of the ground as a mulching amongst bush fruits, &c. For plugging pot plants in, either out-of-doors or in propagating pits, it is invaluable; but as a manure in a fresh state, it should be cautiously applied.—J. G., *Henham*.

FLOWERS AND FOLIAGE.

THE judicious blending of flowers and foliage is one of the most important points to keep in view in connection with the arrangements of cut flowers either in bouquets or vases. Fern fronds are so generally used in such arrangements that they are thought to be in all cases necessary in order to insure successful results; but without questioning their value in many cases, there can be no question that a constant repetition of the same kind of edging or garniture will in a great measure neutralise that variety which constitutes the great charm of a bouquet. Many of our best flowers, such as those of Orchids and bulbous plants, must of necessity depend on extraneous aid in the way of foliage, but in cases it will be found that the leaves belonging to any particular flower used will be found to be the most appropriate and effective garnishing: Roses, for instance, always look best nestling among their own foliage. A half-expanded Rose, with buds and leaf entire, constitutes the best of button-hole bouquets, and a handful of Roses of various colours surrounded and intermixed with their own leaves is the best of all bouquets; or take a vase and fill it in the same manner, and no amount of fringing could add to its beauty or sweetness. The Lily of the Valley, another universal favourite, is exquisitely pretty when arranged along with its own leaves, but, robbed of them, it loses more than half its beauty. Violets are scarcely worth the name when culled without their leaves; and numerous other subjects might be enumerated which fail to give satisfaction when gathered without foliage. The saving in the case of the Ferns, too, should not be overlooked, for what with cutting for floral decorations, garnishing dessert, &c., a heavy drain is generally put on them during the winter season. A very valuable auxiliary in the way of greenery for mixing with cut flowers are the many kinds of scented-leaved Pelargoniums, Myrtles, Diosmas, &c., most of which, grown in a cold house, will last for a lengthened period after being cut; and many hardy subjects, such as Southernwood, Rosemary, &c., might be advantageously employed in the same way. The old-fashioned table bouquet, illustrated in your columns the other day (see p. 63), furnishes a good specimen of both a natural and graceful arrangement.

Henham.

JAMES GROOM.

Culture of Aphelexis.—This is a plant which is easy to grow, and which will last long in flower, and on that account it is well worthy of attention for conservatory decoration. Its flowers, even after being cut from the plant, retain their colours for a long time, therefore they are useful for the decoration of vases and for other indoor purposes. As regards the means of propagation, nothing beats a Cucumber or a Melon frame heated by fermenting material, say stable manure and leaves in equal proportions. The beginning of March is the best time to commence propagating the Aphelexis, cuttings of which are impatient of damp. The cuttings should be taken off with a sharp knife so as to avoid bruising them. They should then be inserted in well-drained pots in a mixture of silver sand and peat in about equal proportions; then place the pot containing the cuttings in another well-drained pot, but 2 in. wider at top outside measure. Fill the space between the pots with silver sand, which saves much time in watering. I find, indeed, that the less water the greater the chance of success. When the cuttings have become well rooted, they should be removed to a 4-in. pot, being careful not to disturb the roots more than can be helped. Well drain the pots, and use a mixture of broken brick and peat soil, to which has been added a little silver sand. I find broken bricks to hold water for a longer time than potsherds. After the young plants have become well established in 4-in. pots I should use the same compost as for the first potting, after which they should be potted in a compost of rough, turfy peat, broken brick, and silver sand. With a little attention to tying and training, young plants raised in this way will be found to give entire satisfaction. *A. hamilis* and *A. rosea*, as well as *A. macrantha* and *A. macrantha purpurea*, are the best kinds to cultivate. I should always use a galvanized wire trellis for *macrantha*, on account of its having long foot-stalks to the flower-stem and its being of a slender growth.—J. O.

Importance of Surface-stirring.—The persistent heavy rains of the past two months have had the effect of reordering the surface of most soils hard and close. It will therefore be more than usually necessary to stir vigorously between growing crops, an operation which should be done on the first favourable opportunity. The importance of this cannot well be overrated, especially after such weather as we have experienced this season.—JOHN CORNILL, *Brighton*.

PLATE LIX.

THE ROCKY MOUNTAIN COLUMBINE.

(*AQUILEGIA CŒRULEA*).

Drawn by Mrs. MILES, Bingham.

In a descriptive article (p. 384, Vol. IX.), wherein I enumerated the distinctive features of the more popular species of Columbine, special attention was directed to the beauty of the slender-spurred species from the Rocky Mountains under Nuttall's original title of *A. leptoceros*, of which I assumed the subject of the annexed figure to be but a mere variation; so beautiful, however, is it, and so fairly constant to the character indicated by James' specific title, *A. cœrulea*, and further, seeing that it has established itself in popular estimation under that title, there will, I think, for once in a way be no harm in waiving the right as regards priority, which the former title certainly possesses. A glance at the figure and a reference to the plate of the Alpine Columbine, which formed the illustration accompanying my article above alluded to, will indicate at once that in these two species we have well-marked types of the two sections into which the genus *Aquilegia* naturally divides itself. In the Alpine form we have the pendent blossoms, the short, incurved spurs, and the somewhat well-shaped form of the corolla; whereas here we have the flowers almost erect, long, slender spurs curved outwards rather than inwards, and a widely expanded corolla, and the individual blossoms measuring from 3 in. to 4 in. in diameter. The foliage is more acutely notched, and of a much more delicate texture than that of our common garden Columbine, and its flowering branches rarely exceed from 15 in. to 18 in. in height. Those who have cultivated it successfully speak in enthusiastic terms of its beauty, a fact amply corroborated by the very truthful representation of it given in the accompanying plate. Its natural habitat is in the ravines of the Rocky Mountains, where it enjoys a partial shade and a moist subsoil. These are two points which the cultivator would do well to bear in mind if he would realize its full beauty. Its naturally delicate foliage is very susceptible of injury from spring frosts and dry, cutting winds, and once nipped in this way, anything like free, vigorous bloom cannot be expected. Under favourable conditions, this plant produces seed freely, and may thus be readily increased, a far better plan than any attempt at division of the old roots. We are indebted to Mr. Thompson, of Ipswich, for the introduction of this lovely plant into European gardens. J. C. NIVEN.

Botanic Gardens, Hull.

Odontoglossum Londesboroughianum.—This in every way handsome and distinct Mexican Orchid has only quite recently flowered under cultivation for the first time in the Londesborough collection, and when exhibited at the Royal Horticultural Society's meeting on December 6 of last year, was awarded a first-class certificate as one of the best Orchids of the then waning year. It was imported by Messrs. Backhouse & Son, of York, nearly ten years ago, and is said to grow naturally in company with another charming and similar habited plant, *O. citrosimum*, the *O. pendulum* of some authors, and which it resembles in the drooping flower-spike and general contour of the flowers. Mr. Denning, who has the honor of being the first to bloom this graceful plant, informs us that the plant has a singular habit of shedding its foliage; so much so, that it might almost be called a deciduous plant, and that it grows well in a moderate temperature along with *Lycastes*, *Zygopetalums*, and *Cypripedium insigne*. The pale green, glossy, pseudo-bulbs are ovate and somewhat flattened, being produced along a creeping rhizome, and they are apparently one-leaved. The younger bulbs are sheathed at the base with the remains of the radical foliage. The plant as exhibited had a simple drooping spike, nearly a yard in length, bearing a dozen or more fully expanded flowers and prominent buds. The sepals and petals are enuculate, with crisped margins, the colour being greenish-yellow, with concentric chocolate brown bars. The reniform tip is more than 1 in. in breadth, and of a clear yellow colour. The column is bent, and is devoid of the anthers at the apex. The whole aspect, especially the colour of the plant, is like that of some of the larger-flowered *Oncids*, and in point of beauty it may well compare with *Oncidium Rogersi*, or its allies, *O. tigrinum*, *O. Marshallianum*, or *O. splendidum*.—B.

1911-12, p. 10. A.M. C. LEMMON. AD. 13. C. CERUEBA - JAMES

HARDY FLOWERS IN LONDON GARDENS.

THE few sunny days with which we have lately been favoured have been the means of bringing into bloom many spring-flowering bulbs and other plants, the colours of which are much brighter than those produced a few weeks ago. Crocuses in variety are flowering profusely in Mr. Barr's grounds at Tooting, especially the sweet-scented, purple-flowered *C. imperati*, *C. versicolor*, and *C. vernus*; Snowdrops, too, of various kinds are very pretty just now, as are also the golden blossoms

Winter Aconite (*Eranthis hyemalis*).

of the Winter Aconite (*Eranthis hyemalis*), which is flowering in great profusion in Mr. Parker's nursery, in which may also be found a bed of *Scilla bifolia* well furnished with dark blue blossoms. The Siberian Squill (*Scilla sibirica*), too, is flowering freely in the Hale Farm Nurseries at Tottenham, where Christmas Roses may also be seen in great beauty. *Primula denticulata* is just opening its bright lilac flowers in warm sheltered places, and the common yellow and purple Primroses, together with their double varieties, are also thickly studied with fully expanded blossoms. The Spring-flowering Meadow

Spring Meadow Saffron (*Bulbocodium vernum*).

Saffron (*Bulbocodium vernum*) is likewise producing its purplish-violet-coloured flowers in great abundance, and several varieties of *Hepatica* are coming freely into bloom in Messrs. Rollisson's Nursery at Tooting. Many plants of *Yucca gloriosa* have during the past week opened blossoms on spikes thrown up some time back, but which, owing to the sunless weather which we have had, have hitherto failed to expand satisfactorily. A few plants of the Great Pilewort (*Ficaria grandiflora*), growing in a border in Ware's Nursery, are producing numbers of bright yellow blossoms from amongst compact masses of healthy foliage, and the great Strap-leaved Saxifrage (*Saxifraga ligulata*) is throwing up strong spikes of delicate flesh-coloured flowers in large quantities. The new white Mule Pink, to which attention was lately directed (see p. 62), is still producing quantities of flowers. S.

COTTAGE GARDENING.

Out-door Cucumbers.

THERE are various expedients that may be readily adopted by those whose means are limited to shelter and protect outdoor Cucumbers in their early stages, and many handy contrivances suitable for cottagers have been designed within the last few years for the purpose of forwarding early vegetables, and I am quite convinced that a handy man, with plenty of time on his hands in the long winter evenings, could manufacture all he may require in this way. Small, light, square boxes, strongly nailed together, from 18 in. to 2 ft. square, with a couple of squares of glass to slide down to form a roof, will be as efficient, and, if kept painted, would last as long as more expensive substitutes. Frames, made of stout wire, in the shape of hand-lights, and covered with oiled calico, are cheap and useful for placing over the plants on cold nights and days in the early period of their growth, and inverted flower-pots will always be found very useful on an emergency. Where a few barrows full of fresh stable manure or any other material that will produce a little warmth can be had, a start should be made about the end of April or beginning of May. They may either be grown in a continuous ridge or on slight hills about 4 ft. or 5 ft. apart. In the former case open a trench 3 ft. wide, and about 1 ft. deep, wheel the manure in, and cover it evenly with the soil taken from the trench, and, if possible, bring some fresh mellow loam, in which to sow the seeds. The manure should be made into a moderately firm compact ridge, from 18 in. to 2 ft. thick if possible, and 6 in. of soil on the top will be ample, as the young plants can be earthed up afterwards as they make progress. A trial stick should be plunged about 1 ft. in the bed, and as soon as the soil is moderately warm the seeds may be planted in groups (five or six seeds in a group), so that a hand-light, flower-pot, or whatever protection may be employed, will cover them. The groups or patches of plants may be placed along the top of the ridge 3 ft. or 4 ft. apart. If the seeds all grow, the weakly plants can be nuprooted, leaving only two or three at something like equal distances apart. The Cucumber season in the open air is usually a short one, and a great deal of the future success in their development depends upon giving the young plants a fair start, taking care not to coddle and weaken them with too much warmth or too much covering. The covers may be kept on till the young plants push through, and then every fine day afterwards; if opaque covering be used, they should be lifted off, of course placing them on again at night, and keeping them on during cold, windy days. With hand-lights, or any other glazed covers, a little ventilation only will be necessary on bright days to keep the plants in a hardy condition until the time comes for the lights to be removed; this should be done gradually, first tilting up the south side on two bricks, and in the course of a day or two the north side as well, letting the young shoots run outside; and as soon as the weather becomes fairly warm and settled, the covers may be taken away, and the usual routine of stopping, pegging, and regulating the shoots, must be gone through; this, however, is not so important a matter with open-air Cucumbers as with those altogether under glass. The shoots of course should be pegged down to prevent the wind from blowing them about and bruising them. Any strong shoot that shows signs of monopolizing too much of the strength of the plant should be nipped at once at the point, and, during the growing season, if a little fresh loamy soil can be sprinkled over the surface amongst the growing shoots, and round the main stems of the plants, about once a week, it will benefit them considerably. Watering will at all times be an important point in their management; at the commencement of the season the water should have the chill taken off by the addition of a little boiling water, and as the quantity required will be small, this will not occasion much trouble; afterwards, when the plants are fully exposed to the air, simply standing the water in the sun for twelve hours will be sufficient. I need not say that liquid manure will be of great service to Cucumber plants when they commence bearing, nor yet that all fruit should be cut when fit for use, unless seeds are required. Wood's Ridge or the Stockwood Ridge will be found as good as any kind. There are certain market growers that by a long course of selection have secured improved strains,

but, as a rule, they do not care about parting with seeds; but what they have done others may do by using the same care in selecting the seed-bearing plants. In favourable situations Ridge Cucumbers may be grown—and, in fact, are grown—without any assistance in the way of bottom-heat beyond that supplied by the sun; but, as I have already stated, an early start, provided no sacrifice is made of health or vigour, means early production. I know a village in Norfolk where years ago a good many of the inhabitants used to plant their gardens principally with Ridge Cucumbers for the Norwich market, and the profit realized was always in proportion to the attention given, especially towards securing an early, healthy, and vigorous start. I am not much in favour of putting out plants that have been started in a hotbed in pots, though I am free to admit that if the seed be sown in single pots, and plunged in a gentle hotbed almost close to the glass, there is no reason why they should not thrive well, if carefully hardened off and planted out under hand-lights or other protection; but too often when raised in a hotbed in this way they are huddled up with other plants, and are ultimately turned out with a weakened constitution, and perhaps covered with insects, and half the season is gone before they recover sufficient strength to bear fruit, and should the season turn out unfavourable, many will perish without bearing fruit at all. A crop of Gherkins may be raised for pickling purposes by simply sowing the seeds in patches, five or six in a patch 4 ft. or 5 ft. apart, in well-prepared land early in June, without any special preparation beyond such good culture as is necessary for other crops of vegetables in garden cultivation.

Growing Vegetables for Market.

An industrious man near a town, with a garden large enough to occupy all his spare time may, and, in fact, often does, realize a profit from it beyond supplying his family with fruits and vegetables. Where circumstances permit of this being done, it will be better to deviate somewhat from the ordinary system of cropping, and to cultivate only those plants that experience has shown can be produced in each particular locality in the greatest perfection. Market gardeners often find it answer their purpose better to concentrate their attention upon one or two special articles, and do this well so as to obtain the command of the market for those particular vegetables or fruits, than to grow an extended selection, acting on the principle that excellence in only a few things is better than mediocrity in a larger number. On warm, dry soils early Potatoes are a paying crop, and they may be cleared off in time to plant the land with Veitch's Autumn Broccoli. The Broccoli would in most cases be off the land by Christmas, which would give plenty of time for ridging it up and preparing it for the Potatoes again; I need hardly add that ground cropped like this must be liberally manured, and the crops must be occasionally changed. Short-top and French Breakfast Radishes are a profitable crop when raised early, and would be cleared in sufficient time for Celery, and this arrangement would make a very good rotation alternately with Potatoes and Autumn Broccoli, as the Celery could be cleared off by Christmas. A good bed of Rhubarb, if well treated and sheltered with litter to encourage early growth, would not cost much to make, and would pay well, while there is always a brisk demand for Seakale in the season, which might profitably be taken advantage of by the enterprising cottager who had a turf-pit or frame with the means of raising a little artificial heat. Early Cabbages, to be cleared off by the end of June or earlier, and the land prepared for Turnips immediately thereupon, would be suitable for some soils, and a good patch of Red Cabbages for pickling will usually find a ready sale at a good profit. Onions sown in the autumn tolerably thick, and drawn green when they are a good size towards the end of May, to be followed immediately by Vegetable Marrows, will make a good change with some of the modes of cropping previously named.

There is one point in connection with gardening for profit I think so important that particular stress ought to be laid upon it, viz., as far as possible to secure the best and truest stocks of each particular plant intended to be grown. Any plant of a good true strain will pay better for the space it occupies, granting the outlay is more in the first instance

for the seeds than the inferior quality, even if the latter have equal germinating power; and with this object in view it may be advisable to devote some attention to the saving of seeds of any really good variety of vegetable, especially as, if this idea be carefully worked out, it may open up another source of profit, cottagers often experiencing a difficulty in securing really good seeds. A careful cottager, who has taken pains in the selection of his plants, will soon obtain a reputation among his neighbours for the excellence of his crops, and may, by saving seeds occasionally, add considerably to his profits. Of course, two of the same family must never be in blossom at the same time, or it will probably result in a crops that will spoil both; this is the main reason why some kinds of vegetables, especially the Brassica family, are so difficult to obtain true to their individual kinds. There are too many varieties (so-called) by half, and every year adds to their number, and renders the confusion still greater. Peas, unless very early or very late, are not as a rule profitable to grow in a small way; French Beans may answer for a change of crops, and the same may be said of Lettuces, and the latter may often be used as a catch crop amongst others; but the main reliance should be placed upon those subjects that are best suited to the soil, and for which the best demand exists in each particular neighbourhood, for the selection of which experience alone will be the surest guide.

There is still another source from which a profit may be realized by those who have some little knowledge of the cultivation of common hardy border flowers, especially those that flower early in spring. There is a large and increasing demand for the decoration of town gardens early in the season by means of Daisies, Wallflowers, Pansies, Pinks, Cloves, Carnations, Sweet Williams, Polyanthus, common Auriculas, &c. They are all easily increased by division, cuttings, or seeds. They may be grown to a flowering size in one year at a very small cost, and could be lited with little balls and conveyed anywhere without feeling much check; and if sold at a rate so as to bring them within the means of the very poor, not only would the transaction be profitable in a pecuniary sense, but it might help to brighten the homes of those who have not too many elevating pleasures. I feel convinced that anything that tends to popularize (if I may use the term) and extend the cultivation of flowers must, in the long run, benefit all concerned in their production. I have ever found that when once a beginning is made and interest aroused, even though in a very slight degree, other and choicer varieties are being frequently added to the stock whenever the means will allow.

Select Vegetables.

BEANS—Dwarf Fan or Cluster, Early Green Long-pod, Seville Long-pod, Broad Windsor. *French*—Long-pod Negro, Canadian Wonder, Scarlet Runners.

BEEF—Henderson's Pine-apple.

BROCCOLI—Dwarf Green Curled, Cottagers'.

BROCCOLI—Veitch's Autumn, Snow's Winter, Early Peuzance, Cooling's Matchless, Cattell's Eclipse.

BRUSSELS SPROUTS—Imported or any good strain.

CABBAGE—Atkins' Matchless, Cocoa-nut, Enfield Market, Red Dutch. *Savoy*—Dwarf Green Curled, King Koffee.

CARROTS—Early French Horn, James' Intermediate, Improved Altringham.

CAULIFLOWERS—Early London, Walcheren, Veitch's Autumn Giant.

CELERY—Sandringham White, Leicester Red, Sulham Prize Pink.

CRESS—Curled.

CUCUMBER—Telegraph, Wood's Ridge.

LEEKS—London Flag, Ayton Castle Giant.

LETTUCES—Paris White Cos, Hicks' Hardy White Cos, Brown Cos, Early Paris Market Cabbage, Tom Thumb.

MUSTARD—White.

ONIONS—White Spanish, James' Long Keeping, Globe, Tripoli, White Lisbon.

PARSLEY—Sutton's Matchless.

PARSNIPS—Hollow-crowned, Student.

PEAS—William the First, Unique, Huntingdonian, Culverwell's Prolific Marrow, Ne Plus Ultra, British Queen.

POTATOES—Ashtop Kidney, Myatt's Prolific, Early Rose Late Rose, Snowflake, Fenn's Early Market, Fenn's Early White Kidney, Patterson's Victoria.

RADISHES—Wood's Frame or Short-top, French Breakfast.

SPINACH—Prickly, or Flanders.

TURNIPS—Cattell's Silver Ball, Orange Jelly, Veitch's Red Globe.

TOMATOES—Orangefield, Hathaway's Excelsior.

VEGETABLE MARROWS—Long White, Moore's Vegetable Cream. E. HOBDAY.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Glass Houses.—Examine Cinerarias, Calceolarias, and Pelargoniums particularly, in order to see that they are free from aphides, for if a single plant be infested by them, they will spread in all directions, giving immeasurably more trouble than if prompt means were taken to destroy them as soon as they appeared. There are many hard-wooded plants, such as Boronias, Polygalas, Tetrathecas, and Aphelexis, upon which aphides will live, although they do not thrive, and yet upon such plants, especially Aphelexis, they are much more difficult to kill than when upon plants for which they have a greater liking, so much so, that Tobacco smoke, when applied in strength and sufficient quantity to destroy them on soft-wooded plants, has next to no effect on them. In such cases I have found nothing equal to a couple of washings with good strong Tobacco water, allowing it to dry on the plants and not washing it off, as is sometimes recommended; this will generally be sufficient to kill not only the mature insects, but also their eggs. A few Gloxinias and Achimenes should now be started; pot the Gloxinias in good loam, to which add some sand and leaf-mould. Achimenes are best treated as follows:—Get some seed-pans, drain them, and let the soil used consist of three parts sifted loam and one-fourth of leaf-mould and sand. By using material of this description their roots do not get broken when shifting them into the pots in which they are intended to bloom. They will be ready for potting when they have grown 2 in. Both Gloxinias and Achimenes should be accommodated with a temperature of not less than from 60° to 65° at night, with a rise of 6° or 8° during the daytime. Till they commence to grow and push leaves they must receive no more water than will keep the soil slightly moist; they are apt to rot if too much be given them.

Pits and Frames.—Fresh stable manure, sufficient to make a good bed for a one or two light frames in which to raise Cucumbers and similar plants, as well as for making beds for Radishes, Potatoes, and Early Carrots, ought now to be got together; it is well to mix the manure with as much in bulk of leaves, as when thus mixed it does not heat so excessively, is ready to use sooner, and keeps its heat better than when manure only is used. The material for these beds, whether it is manure alone or mixed, ought to be well shaken, thrown into a heap, and watered if necessary. In this state let it remain for five or six days, then turn and shake it, an operation which ought to be repeated a second time in a similar way soon afterwards. Rhubarb, that is growing, must have plenty of water, for if neglected at all in this respect it will not come nearly so strong as if properly attended to. Seakale roots, after being forced, ought to be put in sand or ashes; if there be a scarcity of young roots for planting some of these will do when the time arrives for putting them in. A little Lettuce and Cauliflower seed should now be put in in boxes and placed in a house or pit, in which there is a little warmth, if not in a cold frame in a sunny situation where, when the plants are up, covering material can be used for protection if required.

Peaches, Nectarines, &c.—Amateurs who have good fruitful trees of Peaches, Nectarines, or Apricots, will do well this season to bestow an increased amount of labour upon them; the almost unprecedentedly mild winter which, up to the end of January, has given us no frost, is now beginning to show its effects in the bloom-buds, which are pushing unusually early. Where movable coverings exist for the protection of the expanded blooms in spring it will be advisable to put them on at once, and to draw them over the trees every day on which there is any sunshine; thus the already too early movement in the buds will be retarded, a circumstance which will tend more to secure a crop than any amount of protection that can be given to the bloom when it opens too soon. Be sure that in all cases the covering is secured to stakes driven in the ground at the base of the trees, but at such distance from them as to prevent the possibility of the wind causing it to chafe the shoots, or more harm than good will be the result. Where movable shading such as that now advocated is not available the trees will be better left to

themselves than any attempt at this retarding process being made by the use of evergreen branches or anything of a fixed character which has the certain effect of weakening the bloom. Early Apricots that have their bloom very forward had better be pruned and nailed, otherwise, from its advanced condition, it will be sure to be a good deal knocked off in the operation.

Bush Fruits.—Where a mixture of lime and soot was dusted over Gooseberry and Currant bushes about the close of the year, in order to prevent birds from attacking the buds, the continuous rains will have washed it off considerably; and as the time is approaching when these little feathered marauders commence their attacks, it will be well to give the trees another dusting. Where white threads have been strung over these bushes for a similar purpose and have become discoloured, a few more strands should be run across them, as upon the fresh white appearance of the material depends its deterrent powers. Any pruning that yet remains to be done in regard to the above fruits—Raspberries, Apples, Pears, Plums, or Cherries—either in the open ground or on walls, should at once be brought to a close.

Peas sown in the open ground about the beginning of the year on slightly elevated ridges, and covered as then recommended with dry material, will, except in moisture-holding soils, be secure, but where there are any doubts, it will be well to examine the seed, in order to see that it is not rotten through the excessive rainfall to which it has been subjected; where this is found to be the case, a fresh sowing should be made immediately, otherwise there will be a blank in the crop. Of Turnip Radishes another bed should now be sown, covering it with litter, as recommended for the first sowing. As Brussels Sprouts and Savoys are cleared off the ground, it should be manured and dug; but if there be not a good stock of Cottagers' Kale, Curled Greens, and Coleworts, it is not advisable to remove the old stools of these, for if left, they will furnish a supply of sprouts during the spring that will be found very serviceable.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

February 5.—Sowing a few Sweet Peas and Syon House Cucumber. Potting off Melons and plunging them in sawdust to keep them from slugs; also potting off some Mignonette for Tree Mignonette and placing it in a light, cool place. Shifting first Cucumbers and potting second lot. Potting Hydrangeas and Miss Nightingale Heliotropes, and placing them in heat. Pricking-off Lobelia speciosa cuttings. Examining blocks in Cattleya and Odontoglossum houses. Re-doing up Lælia autumnalis in Moss and charcoal. Putting in some double Senecio cuttings; also those of Coleus and of Centaurea gymnocarpa, C. candidissima, and Stephanotis. Putting in likewise more cuttings of Patunia, Verbena, Cerastium, and scented Verbena. Planting Box trees in shrubbery borders; also some Cauliflowers under hand-glasses, giving three shovelfuls of manure to each glass; likewise some Horseradish on ridges, laying the thongs horizontally. Placing another crop of Keen's Seedling Strawberry plants in heat. Covering up some Rhubarb and Seakale with boxes and embedding them in leaves. Shifting Borage into larger pots to get it into flower. Finishing nailing Apricots and beginning to nail Peach trees.

Feb. 6.—Sowing Walchereu and Early London Cauliflower in frame; also Capsicums and Chrysanthemum carinatum fl.-pl. Potting off Heliotropes, and placing them in heat; also potting off young Gazanias, and putting them into heat. Potting Rhododendrons in peat for forcing. Potting Disa grandiflora in peat. Putting in another batch of Asparagus. Raising Cattleya-house to 58° at night and 63° by day. Red-leading Peas to keep birds off them. Putting ashes over more Peas just coming up. Top-dressing the inside borders of second Muscats and Hamburghs with manure. Putting some manure to Asparagus beds. Mixing up some manure and leaves for Cucumber-pit. Making a new Vine border of good sandy turf only. Sooting between rows of Cabbages. Stirring up the soil about young Mignonette. Graveling walks and rolling new gravel. Top-dressing Peppermint-beds with leaf-soil. Looking over wall-tree coverings, making new ones, and repairing old ones. Making canvas coverings for Green Gage Plums. Earthing-up the first Peas.

Feb. 7.—Sowing Bromham Hall Melon, Parsley, and Viola Intea. Potting Salvia splendens and Guaphalium. Putting in more cuttings of Achyranthus, Fuchsia, Scutellaria, and Tropæolum called Crystal Palace elegans. Putting in another forcing of Rhubarb. Putting a few pots of Musk in heat. Looking over Apple stores. Top-dressing pot Vines with manure. Levelling Vine

borders and putting on a dressing of bones. Making some frames ready for Heaths. Clipping Holly hedge. In flower out of doors—Snowdrops and *Eranthes hyemalis*.

Feb. 8.—Sowing *Wigandia*, *Polymnia*, *Hedychium*, and *Phorium tenax*; also East Lothian Stocks, *Nasturtium canariense*, *Petunia*, *Cyclamen*, Golden Feather *Pyrethrum*, and *Rhodantho*; also sowing *Chilias*, *Borage*, *Marjoram*, *Basil*, *Egg Plant*, and *Tomato*. Potting cuttings of *Croton variegatum*, *Sericographis*, *Salvia patens*, first-struck *Fuchsias*, *Verbenas*, *Mangles' Pelargoniums*, and second-sown *Cucumbers*. Re-doing-up *Saccolabium guttatum*, using crocks and Moss. Potting *Dendrochilum filiforme* in Moss and peat. Putting old *Fuchsias* into heat for cuttings. Putting dwarf *Roses* into second *Peach-house*; also shading to *Odontoglossum-house*. Giving first *Peach-house* trees a good watering; also a good top-dressing to *Roses*, young *Apple trees*, *Tulips*, and *Hyacinths*. Manuring *Black Currants*. Raising second *Peach-house*, which is in full flower, to 55° at night.

Feb. 9.—Sowing *Verbena venosa*, *Chamæpeuce diacantha*, *Echeveria*, *Melianthus*, and *Cineraria acanthifolia*. Potting *Gazania splendens*. Putting in a few cuttings of *Lavandula dentata*; also some *Willow cuttings*. Planting four lights with sprouted *Ash-top Potatoes*. Dusting *Plum trees* with soot, as birds are injuring the buds. Earthing earliest *Potatoes*. All pot *Hampshire Grapes* ready for thinning, except *Foster's Seedlings* which is setting.

Feb. 10.—Potting *Gloxinias* and *Caladiums*, and putting them into moist heat. Dipping *Strawberry plants* for green fly. Camel-hair brushing flowers of *Strawberry plants* in *Fig-house*. Sending away *Lady Downe Grapes*. Topping and otherwise trimming *Turnips*, and placing them in a cool place in ashes. Top-dressing *Peach trees* in pots with half *cow-manure* from farmyard and half *barut refuse*. Cleaning up *wood-walk sides*. Keeping *East Indian Orchids* drier than usual, in order to induce them to flower.

Orchids.

Barkerias are among the most troublesome plants with which the *Orchid grower* has to deal, not so much perhaps on account of their being difficult to manage, for when placed in a suitable temperature and position that is not the case, but because, owing to the smallness of their growth, they are particularly liable to be affected by excess of either heat or cold, or to be irretrievably injured by the rays of the sun in summer; thus it is that many *Orchid growers* who know well the culture of these plants frequently lose them by misadventure, and the large importations which are from time to time received in a couple of years dwindle down to a few specimens. The *Barkerias* thrive best when fastened to blocks without *Sphagnum Moss* or other material. They are very impatient of dry heat, and should be suspended on the shady side of an intermediate-house within a few inches of the glass. If a moist wall exist in either the intermediate-house or the warmer end of the cool *Odontoglossum-house*, the safety of the plants may be insured during both the growing and resting seasons by having them suspended as near the glass as convenient, and within 1 in. or so of the brick wall. By this means the frequent waterings and alternations between wet and drought, so injurious to the plants, will be avoided; and having a genial humid atmosphere around them at all times they will seldom require water during the resting season, but will be preserved from being dried up, and during the growing season, when they should be kept wet, they will receive the full benefit of the water given them, which would evaporate in a few hours if the plants were placed in a dry situation. *Barkerias*, like many other small-growing *Orchids*, are rather capricious; and once having found a situation in which they thrive well, the cultivator should be very careful about moving them to another place. The temperatures during February should be—*East Indian* or warm house, 65° by day and 60° at night; *Cattleya* or intermediate house, 55° by day and 50° at night; *Odontoglossum* (*New Granada*) or cool house, 50° by day and 45° at night; the day temperature being allowed to rise 5° to 10° by sun-heat, admitting air on every occasion when the weather outside will permit. Those who have but one house should treat it as an intermediate one.—JAMES O'BRIEN.

SMALL SIZE OF THE TREES IN PARIS.

The French deserve praise for so liberally embellishing Paris with trees, yet though they have been planted for many years it is a curious fact that there are no big trees in the streets or avenues of Paris! And not only no big trees, but scarcely a medium-sized one! It is not the fault of the poor trees, or the soil, or the air. It is caused by a system of management apparently based on the notion that trees, like soldiers, are best arranged in close order, or like the poor fellows who find a last rest in the *Fosse Commune* without any earth between the boxes. There is no evidence whatever that any one responsible for the street trees of Paris has the least idea of the beauty of hardy trees when well developed. At best they are only seen a little better grown than in the nursery garden. They are everywhere with heads crowded together—starving for want of space above and below. Two or three *Planes* usually stand where one fairly-developed tree would be sufficient. Often the *Planes* may be seen running up before the tall houses in the finer streets with a stem before every window. Some of the trees on the *Thames embankment*, although only a few years planted, are now almost as large as the best in Paris. If we only thin in a bold and timely manner, a very few years will see the embankment trees better specimens than any in Paris. The *Plane trees* in our squares are far finer than any there, owing to the fact that they had room to grow and were not pruned. Pruning, to throw the strength of a tree or shrub into fruit or flower or into some shape desired by the cultivator, is a rational and often very successful process, but nothing of the kind can be said of the pruning of any grown forest or ornamental tree: to prune them is to destroy their beauty, individuality, and dignity. In Paris pruning into a miserable uniformity is carried out to a deplorable extent. It would be difficult to make Parisians understand how much beauty they are thus deprived of. Few of them have any idea of what a grown tree really is. Their trees are only sticks with leaves at the top, much like the ostrich, which wears a few graceful plumes by way of apology. These remarks apply to trees in open spaces as well as in the street, which are, however, often wide enough to admit of fair development. If this system is to go on, it will be wise of the educational powers now doing so much for young France to plant a few acres with native and hardy trees to be allowed to assume their full size and natural development. One does now and then see in the etchings in the shop windows a portrait of a fine tree, but where it is so easily done it is desirable to have living examples. It has been said to the writer that fine trees cannot be grown in Paris, but that this is not the case is proved by the existence of occasional good specimens in courts and small gardens, which the municipal pruners did not visit. Sometimes, when "demolitions" are in active progress, a fine old tree may be now and then seen as the houses are taken down around it. In such positions the conditions are by no means so favorable to tree-growth as in the many open streets and wide avenues. Along the quays, too, where the trees might throw their arms over the water on one side, and over a wide hot road on the other, they are just as prim and as unlike fine trees as they are anywhere else; no doubt, in some narrow streets very wide-spreading trees are not desirable, but in such cases the right way is to select species and varieties which will suit the position without needless mutilation. V.

Hemlock Spruce Hedges.—The *Hemlock Spruce* can scarcely be excelled in form, health, or vigour for hedges. We ("Moore's Rural") have seen one 300 ft. long, and 6 ft. high. It was planted eight years since, the soil trenched 2 ft. deep and 4 ft. wide, well enriched, and small plants less than 1 ft. high were set in the centre of the prepared space. Not a plant died the first season or since. Its beauty and vigour we attribute to two things—thorough preparation of the soil before planting, especially the trenching, and the annual pruning in spring. There is certainly no secret in this, and there is no good reason why just such hedges should not be seen upon every property, the owner of which has an eye for ornaments of this kind. There is certainly no hardy evergreen equal to the *Hemlock Spruce* for ornamental hedges.

Rose Stocks and Spring Frosts.—Mr. Richard Smith, of Worcester, who grows many thousands of *Tea Roses* every year, propagates them in heat by grafting them on the *Manetti stock*. The operation is begun during November, and many of the plants when grafted flower the following May. The *Manetti stock* is, however, very easily excited into growth in spring, much more easily, indeed, than the common *Brier* and other *Rose stocks*, and as a consequence *Roses* on the *Manetti* suffer from spring frosts under conditions in which the same varieties worked on *Brier stocks* escape injury.

THE LATE CANON KINGSLEY'S HOUSE AND GARDEN.

THAT the late Canon Kingsley was devotedly fond of plants of all kinds, none who knew him or who have read his books will doubt, but his heavy clerical and literary duties prevented him from paying that attention to horticulture which otherwise he would doubtless have done; still, that he entertained a taste for the beautiful in matters pertaining to gardening will be seen by the annexed view of Eversley Rectory. The engraving shows the south front of the Rectory, the open glass door being the entrance to Canon Kingsley's study. The house is literally covered with vegetation, consisting of Magnolias, Wistarias, Japanese Honeysuckle, Ceanothus, Roses, and Ivy. The garden, which is but of small extent, consist of a mixed border of hardy flowering plants and Creepers, seen on the right of the picture, and a solitary circular bed on a Grass plot at the opposite end, filled with similar plants. The eastern

ECCENTRICITIES IN AURICULAS.

I AM at present engaged in making a collection of what, for want of a better term, I have designated "eccentricities" in Auriculas, *i.e.*, departures from what we have come to regard as correct forms. A remarkable illustration of the singular variation to which Auriculas are liable occurred last spring in the vicarage garden, Kirkby Malzeard, Ripon, the residence of that well-known Auricula cultivator, the Rev. F. D. Horner. Mr. Horner had crossed two very fine stage Auriculas: one a very fine grey-edged sort, the other an equally fine green-edged kind, and among the progeny was a number of exceedingly nondescript forms, having the paste white, the ground colour yellow, and the edging of a lovely green. Some were pure yellow selfs, and many had broken into other forms as grotesque as they were varied. It seemed as if the pollen of a yellow self like Gorton's Stadtholder had been used to fertilize one of the fine-edged Auriculas, though Mr. Horner

The late Canon Kingsley's House and Garden.

or carriage front of the house is also clothed with plants, the front entrance being through a small greenhouse in the form of a verandah, and on the lawn are three fine Scotch Firs, the top of one of which is seen in the engraving. Under the shade of this tree lie the remains of the late Canon, the churchyard wall being also the boundary of the rectory garden, a fit resting place for one who in life was so attached to what he termed "dear Eversley." The rectory and church, and also the surrounding scenery, are all of the most picturesque description. The walls of the churchyard are completely covered with Ivy, Cotoneasters, Wild Roses, and Honeysuckle, intermixed in the most charming manner. At the entrance is an avenue of Irish Yews, and on either side of the path leading from the rectory to the church porch, are some very fine specimens of Chinese Junipers. Tall Lombardy Poplars covered with Ivy, large Yews, Arbor Vitas, and Portugal Laurels, are so intermingled as to render the late Canon's garden well worth a visit.

W. W. H.

stated that nothing of the kind had occurred. I quite envied Mr. Samuel Barlow, Manchester, the possession of a basket of these singular seedlings that he took with him, and he has a large collection of these grotesque forms that are of a most interesting character. Mr. Horner sent me one peculiar green flower which he called "Jolly Green." It bears self-green flowers of great size, with a slight zone of white paste round the tube. One wonders what progeny seed taken from this variety would be likely to produce. Another eccentric seedling I have is, to my mind, very charming: there are the yellow tube and the white paste, but instead of the dark ground colour a broad band of silvery grey reaches to the very edge. The foregoing are but a few of many forms that I am gradually gathering together. The Alpine flowers also have yielded some singular novelties, some as yet only prematurely developed, but full of promise of a quaint originality. The more grotesque they are the greater is the interest which they possess.—Quo.

TREES AND SHRUBS.

IMPROVEMENT OF PARK SCENERY.

SUFFICIENT attention is not directed to park planting, with a view to render the landscape scenery picturesque and varied, when marginal masses, young plantations, clumps, or groups are being formed in new parks; it is also necessary from time to time to fill up blanks in park plantations occasioned by high winds or the decay of trees, if a succession of healthy growing timber be desired throughout the country. Before selecting the subjects to form the principal masses, it is essential to have some knowledge of the trees most suitable to the various conditions of soil, geological formation, and climate; as a general rule, it is the safest and perhaps the wisest plan to plant the park belts, marginal masses, and the larger clumps and groups with those trees that are found to thrive best and to develop into the finest timber in the locality where the planting is intended to be carried out. Trees suitable for forming the principal masses in the park may be divided into two classes, thus:—Oak, Elm, Lime, Horse and Sweet Chestnut trees, for rich, loam, and clay soils, and somewhat sheltered sites; Beech, Sycamore, Norway Maple, and Birch trees for thin poor soils and in exposed sites. Among Conifers (though not strictly park trees) the Wellingtonia, Silver Firs in variety, Douglas and Menzies Spruces, and Pinus austriaca, Laricio, Benhamiana, Jeffreyi, ponderosa, macrocarpa, and many other hardy and tall-growing varieties, may be planted on the declivities of hills in groups amongst the marginal masses to give variety, contrast, and shelter; they can also be planted in groups to form a background to deciduous trees on prominent hills in the distance to break the hard, level, sky outline. The best and at the same time most pleasing and picturesque effect in park planting is to be produced by grouping with distinct species bold, sweeping masses of different sizes and irregular shapes to avoid giving similarity in size and form of groups of each distinct kind of park tree, and by planting smaller groups of the newer and more beautiful varieties of each species in front of the common sorts, distributing these latter at wide and irregular distances apart from tree to tree, so as not to add a stiff and clump-like appearance to the larger masses. By a judicious arrangement of groups of ornamental trees and dwarf tree forms, they should exhibit a different outline to the eye on every side; and although they should be planted at wide distances apart to allow every tree sufficient room to develop its special features of habit and foliage to the fullest extent, yet still these, when viewed at a distance, should blend into one group. Clumps of park trees are generally round or oval in shape, and mostly planted on prominent knolls. They should be composed of one distinct variety or species. Groups of dwarf trees may be advantageously used to soften down abrupt outlines of clumps. Mixed groups of fine-foliaged and flowering trees, of silvery and dark-foliaged, of rich autumn-tinted and the more quiet coloured, and the round-headed with the fastigiated forms, the weeping with the irregular or oblong forms, should be tastefully distributed throughout the park, advantage being taken of the undulating surface by planting the groups on the rising ground, leaving the hollows or valleys to form grassy glades. These latter may occasionally be broken when too great a breadth of grass is visible, by planting groups of dwarf trees in the foreground. Thorns and other dwarf trees should also be planted near carriage drives, and on each side of sharp curves of park roads and drives in scattered groups of various sizes from a triplet to a score or more. These dwarf-tree forms, when planted judiciously, give variety without abruptness and a more natural appearance generally to the planting. Single specimen trees of distinct and marked features should be planted on well-chosen spots, but care must be taken not to plant too many so as to give a speckled or chessboard-like appearance to the park. The leading features to be aimed at in park planting should be variety, with distinctiveness, and system of arrangement without formality. Conifers are only suited for park adornment at a distance from the mansion, on the sides of hills or prominent high-lying outskirts; when planted in the foreground or in the low-lying

sites of parks either in clumps, groups, single specimens, or to form avenues, they are altogether out of character with true English park landscape planting. The only exception to this rule is the Cedar of Lebanon, which may be tolerated near a mansion, but even this only when the style of architecture is Elizabethan, Tudor, Jacobean, or of some other allied type.

The following is a list of trees suitable for park planting, arranged under the following heads. Those marked (*) are of a shrubby habit of growth; they should be trained to one stem to form dwarf trees, or grafted on standards.

Trees

With Beautiful Foliage, Singularity of Habit, or otherwise Remarkable, suitable for Grouping.

Ailantus glandulosa	Quercus macrophylla
Alnus glutinosa imperialis and laciniata—Alder	Quercus macrophylla Albertsi
*Aralia spinosa	Quercus paunonica
Betula asplenifolia—Fern-leaf Birch	Quercus panosa
*Broussonetia papyrifera	Quercus pectinata
*Carya alba—White-nutted Hickory	Quercus Cerris
Catalpa syringifolia	*Rhus glabra laciniata—Cut-leaved Sumach
*Celtis australis—Nettle Tree	Salix annularis—Ring-leaved Willow
*Corylus Colurna—Constantinople Hazel	Salix Basfordiana—branches and twigs rich orange-coloured
Dimorphanthus Mandshuricus	Salix fragilis
*Euonymus verrucosus—Wanted-barked Spindle tree	Salix monspeliensis
Fagus asplenifolia—Fern-leaf Beech	Salix pentandra—Sweet-scented Willow
Fagus cristata—Crested Beech	Salix Russelliana
Fagus ferruginea—American Beech	Salix sanguinea—Red-twigged Willow, very brilliant
Fraxinus americana latifolia	Sophora japonica
Fraxinus heterophylla	*Staphylea trifolia—Bladder-nut Tree
Fraxinus lentiscifolia	Tilia dasystyla—handsome variety; foliage keeps green, and hangs on till late in autumn
Gleditschia horrida	Tilia heterophylla
Gleditschia triacanthos	Tilia microphylla
Juglans macrophylla	Tilia rubra—Red-twigged
Juglans nigra	Tilia laciniata
Juglans regia laciniata	Tilia anrea—Yellow-twigged
*Paliurus aculeatus	Ulmus suberosa vulgaris
Paulownia imperialis	Ulmus campestris viminalis
*Planera Richardi—Zelkova tree	Ulmus suberosa effusa
Platanus occidentalis	Ulmus montana glabra
Platanus orientalis	Ulmus montana major
Platanus orientalis acerifolia palmata	*Nantboxylum fraxinenum—Tooth-ache Tree
Populus tremula	*Zizyphus vulgaris—Jujube Tree
Populus angulata	
Populus balsamifera	
*Pterocarya caucasica	
*Ptelea trifoliata	
Quercus Egilops	

Remarkable for their Autumn Tints.

Æsculus, of sorts—Horse Chestnut	Cratægus Layi
Acer saccharinum—Sugar Maple	Cytisus alpinus—Scotch Laburnum
Acer rubrum—Red Maple	*Euonymus europæus—Common Wild Spindle Tree
Acer platanoides—Norway Maple	*Euonymus latifolius
Acer spicatum—Spike-flowered Maple	Fagus, of sorts—Beech
Acer colchicum rubrum—Colchic Maple	Fraxinus excelsior anrea
Acer striatum—Striped-barked or Snake-barked Maple	Liquidambar styraciflua—Sweet Gum Tree
Acer tataricum—Tartarian Maple	Liriodendron tulipifera—Tulip Tree
Acer macrophyllum—Large-leaved Maple	*Parrotia persica
Acer platanoides laciniatum—Eagle's Claw Maple	*Pavia, of sorts—Smooth Horse Chestnut
Acer pinnatifidum—Pinnatifid Maple	Quercus coccinea—Scarlet Oak
Acer platanoides dissectum—Cut-leaved Norway Maple	Quercus rubra—Red Oak
Carpinus Betulus—Hornbeam	Quercus alba—White Oak
Carpinus Betulus incisa—Hornbeam	Quercus nigra—Black Oak
Castanea, of sorts—Sweet Chestnut	Quercus tinctoria
Cerasus sylvestris—Wild Cherry	Quercus falcata
*Cornus mas tricolor—Dogwood	Quercus americana laciniata
Cratægus cordata	Quercus imbricaria
Cratægus coccinea	Quercus macrophylla
Cratægus Crus-galli	Quercus palustris
Cratægus flava	*Rhus typhina—Stag's-horn Sumach
Cratægus flava trilobata	*Rhus vernix—Swamp Sumach
Cratægus grandulosa	Salisburia adiantifolia—Maiden-hair Tree
Cratægus purpurea	Taxodium distichum—Deciduous Cypress
Cratægus rigida	Ulmus, of sorts—Elm
Cratægus tenacetifolia	*Virgilia lutea
Cratægus nigra	*Viburnum Lantana
Cratægus prunifolia	*Viburnum opulus

With Silvery or Glaucons Foliage.

- **Elæagnus argentea*—Wild Olive
- **Elæagnus hortensis*—Wild Olive
- Fraxinus argentea*—Ash
- **Halimodendron argentea*—Silver Salt Tree
- **Hippophæ rhamnoides*—Sea Buck-thorn
- **Hippophæ salicifolia*—Sea Buck-thorn
- Populus alba* (Abele)—White Poplar
- Populus canescens*—Grey Poplar

- Populus argentea*—Silver Poplar
- Pyrus domestica*—True Service
- Pyrus Aria*
- Pyrus salicifolia*
- Pyrus nivalis*
- Pyrus pinnatifida lanuginosa*
- Salix alba*—White Willow
- Salix caudata*
- Salix regalis*
- Salix Huntingdonensis*
- Tilia argentea*—Silver Lime

Flowering and Fruit or Berry bearing.

- Æsculus Hippocastanum*—Horse Chestnut
- Æsculus Hippocastanum rubra*
- Æsculus Hippocastanum fl.-pl.*
- Æsculus Hippocastanum laciniata*
- **Amelanchier Botryapium*
- Amygdalus domestica*
- Amygdalus persica*
- **Calophaca wolgarica*
- **Caragana arborescens*
- **Caragana grandiflora*
- Carpinus Betulus*—Hop-flowering
- **Cerasus Padus*—Bird Cherry
- Cerasus sylvestris*—Wild Cherry
- **Cercis siliquastrum*—Judas Tree
- Cerasus multiplex*—Double Pink Cherry
- **Cornus alba*—Dogwood
- **Cotoneaster affinis*
- **Cotoneaster acuminata*
- **Cotoneaster frigida*
- **Cotoneaster nummularia*
- Cratægus Oxyacantha fl.-pl.*—Double White
- Cratægus Oxyacantha coccinea*—Single Scarlet
- Cratægus Oxyacantha punicea fl.-pl.*—Paul's Double Scarlet
- Cratægus Oxyacantha rosea fl.-pl.*—Double Pink

- **Kolreuteria paniculata*
- Magnolia glauca*
- Magnolia glauca Thompsoniana*
- Magnolia tripetala*
- Magnolia macrophylla*
- Magnolia acuminata*
- Magnolia cordata*
- Malus alba fl.-pl.*—Double White
- Malus floribunda*—Many-flowered
- Malus rosea fl.-pl.*—Double Rose-flowered
- Malus spectabilis*—Chinese Crab
- Malus prunifolia*—Siberian Crab
- Morus rubra*—Red Mulberry
- Morus nigra*—Black Mulberry
- Morus alba*—White Mulberry
- **Pavia macrostachya*
- **Pavia discolor*
- **Pavia flava*
- **Pavia rubra*
- Prunus triloba*—Double Pink Plum
- Prunus virgata*—Double Pink Plum
- Prunus alba-pleno*—Double White Plum
- Prunus spinosa*—Single White Sloe Tree
- Pyrus aucuparia*—Mountain Ash
- Pyrus vestita*
- Pyrus torminalis*
- Robinia Pseudo-Acacia*
- Robinia Pseudo-Acacia hispida*—rose
- Robinia Pseudo-Acacia lutea*—yellow
- Robinia Pseudo-Acacia purpurea*—purple
- Robinia Pseudo-Acacia Decaisueana*—rose
- Robinia Pseudo-Acacia Bessoniana*—Besson's
- Robinia Pseudo-Acacia monolifera*
- Robinia Pseudo-Acacia inermis*
- Robinia Pseudo-Acacia macrophylla*
- Robinia Pseudo-Acacia viscosa*—rose

- And many others
- Cytisus Laburnum*—English Laburnum
- Cytisus alpinus*—Scotch Laburnum
- Cytisus serotina*—Autumn-flowering Laburnum
- Cytisus quercifolia*—Oak-leaved Laburnum
- Cytisus purpurea*—Purple-flowered Laburnum
- Cytisus flore-alba*—White-flowered Laburnum
- **Euonymus europæus*—Common Wild Spindle Tree
- **Euonymus latifolius*—Broad-leaved Spindle Tree
- Fraxinus Ornus*—Flowering Ash
- **Gymnocladus canadensis*—Kentucky Coffee Tree
- **Halesia tetraptera*—Snowdrop Tree
- **Halimodendron subvirescens*—Salt Tree

- **Viburnum Opulus*—Snowball Tree
- **Viburnum laevigatum*
- **Viburnum prunifolium*
- **Viburnum Lantana*
- **Viburnum plicatum tomentosum*
- **Viburnum cassinoides*
- **Viburnum Lentago*

With Variegated Foliage.

- Acer Negundo variegatum*—Maple
- Acer Pseudo-Platanus variegatum*—Sycamore
- Acer Pseudo-Platanus purpureum variegatum*
- Carpinus Betulus variegata*—Hornbeam
- Castanea vesca variegata*—aurea
- Castanea vesca variegata*—argentea
- **Cerasus Mahaleb variegata*—Mahaleb
- **Cercis Siliquastrum variegata*—Judas Tree
- **Cornus mas variegata*—Dogwood
- **Euonymus latifolia variegata*—Broad-leaved Spindle Tree
- Fagus sylvatica variegata*—Beech
- Fraxinus excelsior variegata*—Ash
- Fraxinus excelsior argentea variegata*
- Liriodendron tulipifera variegata*—Tulip Tree

- Platanus occidentalis variegata*—American Plane
- **Ptelea trifoliata variegata*—Trefoil Tree
- Quercus Cerris variegata*—Silver-edged Turkey Oak
- Quercus pedunculata variegata*—Oak
- Quercus Ilex variegata*—Oak
- Sophoris japonica variegata*
- Tilia ulmifolia variegata*—Lime
- Tilia argentea variegata*—Lime
- Ulmus campestris variegata*—English Elm
- Ulmus suberosa variegata*—Dutch Elm
- Ulmus montana variegata*—Scotch or Wych Elm
- Ulmus major variegata*—Scotch or Wych Elm

With Rich Deep-coloured Foliage in Summer.

- Catalpa syringifolia aurea*
- **Corylus Avellana purpurea*—Purple Hazel
- Cytisus Laburnum aurea*
- Cytisus alpinus aurea*—(Smith's new)
- Alnus glutinosa aurea*—Golden Alder
- Acer colchicum rubrum*—Red Maple
- Acer purpureseus*
- Acer polymorphum roseum*
- Acer polymorphum rubrum*
- Acer Pseudo-Platanus purpureum*
- Acer Pseudo-Platanus rubrum*
- Betula purpurea*—Purple Birch

- Fagus sylvatica purpurea*—Purple Beech
- Fraxinus excelsior aurea*—Golden Ash
- Populus canadensis aurea*—Golden Poplar
- **Euonymus europæus purpureus*—Purple Spindle Tree
- Quercus concordia*—Golden Oak
- **Sambucus nigra aurea*—Golden Elder
- Ulmus campestris purpurea*—Purple Elm
- Ulmus campestris Rosseelsi*—Golden Elm

Suitable for Avenues.

- Elm—English
- Elm—Dutch
- Plane—P. orientalis
- Plane—orientalis acerifolia
- Plane—occidentalis
- Lime—Red-twigged
- Lime—Yellow

- Lime—*Tilia dasystyla*
- Oak—Common
- Oak—Scarlet
- Beech—Common
- Tulip Tree
- Horse Chestnut
- Sweet Chestnut

Weeping.

- Almond
- Ash—Common
- Ash—Mountain
- Birch—laciniata pendula
- Birch—Young's New
- Beech—Common and Purple-leaved
- **Caragana pendula*
- Cherry—*Cerasus pendula*
- Elm—American
- Elm—English
- Elm—Camperdown
- Elm—Scampston
- Elm—myerophylla pendula
- Elm—Dutch
- Elm—Scotch
- Gleditschia pendula*

- Hornbeam pendula
- Laburnum—English
- Lime—Common and Silvery
- Populus tremula pendula*
- Populus grandidentata pendula*
- Quercus ægilops pendula*
- Quercus americana pendula*
- Quercus pedunculata pendula*
- Robinia Pseudo-Acacia pendula*
- Saphora japonica pendula*
- Thorn—*Cratægus pendula*
- Juglans regia pendula*
- Willow—American
- Willow—Babylonian
- Willow—Fox's New
- Willow—Kilmarnock

Evergreen and Sub-Evergreen.

- Castanea chrysophylla*
- **Cotoneaster frigida*
- **Cotoneaster affinis*
- **Cotoneaster acuminata*
- **Cotoneaster nummularia*
- Quercus Lucombiana*
- Quercus Pseudo-Acacia crispa*
- Quercus Lucombiana dentata*
- Quercus Lucombiana suberosa*
- Quercus Lucombiana incisa*

- Quercus fulhamensis*
- Quercus Wheeleri*
- Quercus Thuneri*
- Quercus Pellois*
- Quercus Ilex*
- Quercus Ilex latifolia*
- Quercus Suber* in variety
- Quercus virens*
- Quercus Fordi*
- Ulmus chinensis*

Habit or form of Head.

FASTIGIATE.

- Birch, fastigate
- Cypress, deciduous (*Taxodium distichum*)—pyramidal and spiral
- Elm, fastigate
- Elm, columnar
- Elm, Dampier's pyramidal
- Lime, pyramidal
- Locust Tree, pyramidal
- Oak, pyramidal
- Oak, fastigate
- Plane, pyramidal
- Poplar, fastigate
- Poplar, fastigate giant
- Pyrus, pyramidal
- Salisbury, spiral

ROUND-HEADED.

- Ash
- Beech
- Elm, Scotch
- Elm, Dutch—round when old
- Elm, English (oblong and irregular when young)
- Horse Chestnut
- Lime—pyramidal and oblong when young
- Oak
- Robinia Pseudo-Acacia inermis*
- Sweet Chestnut
- Sycamore
- Plane
- Maple
- Willow

Longleat.

GEORGE BERRY.

Destroying Stumps of Trees.—The following receipt is reported to have proved very successful in the backwoods of America:—In the autumn bore a hole 1 in. or 2 in. in diameter and 18 in. deep, put in 1½ oz. of saltpetre, fill with water and plug up close. In the following spring put in the same hole half a gill of kerosene oil, and then light. The stump will smoulder away without blazing, even down to every part of the roots, leaving nothing but ashes.

Laburnum in Flower in the Isle of Wight.—A large Laburnum tree growing at St. Helen's, a little village about 2½ miles from Ryde, is now in full flower. I have not had time to go and see it myself, but I am told it is quite a picture, looking more like May than January.—H. EWBANK.

A FEW MORE GOLDEN VARIEGATED DECIDUOUS TREES.

THE list of golden variegated trees given in your last issue (see p. 79), appears to me to be incomplete without the enumeration therein of the following beautiful varieties of recent introduction, chiefly from Continental nurserymen:—(1) The new Golden Variegated Dogwood (*Cornus mas. elegantissima*), recently sent out by Messrs. Lee & Sons, of Hammersmith, quite one of the most constant and beautiful, as well as one of the most profusely marked variegations I have yet seen, all the leaves being broadly and clearly margined with gold, besides being sometimes towards the end of the season also streaked and spotted with rose colour. (2) *Ptelia trifoliata aurea*, a most distinct, conspicuous, and beautiful golden variegated form of this comparatively well-known shrub, and though as yet new and scarce in this country, it is apparently of by no means recent introduction in Belgium, if one may judge from the low price at which it is offered by the nurserymen there. (3) The Golden Poplar (*Populus vulgaris aurea* Van Geerti), a beautiful all-golden form of the Common Poplar, sent out by the well-known Belgian nurseryman whose name it bears. (4) The Golden Laburnum (*Cytisus Laburnum aureus*), a most distinct and beautiful all-golden-foliaged tree, recently sent out by Mr. Richard Smith, of Worcester. (5) *Weigelia Loozmansi aurea*, a fine novelty, with golden-yellow leaves usually surrounded with a slender edging of fine carmine-red, very constant in its variegation, and now being distributed by M. Van Houtte, of Ghent. (6) *Clerodendron Bungei variegatum*.—This, though hardly deserving enumeration among golden variegated hardy shrubs, still comes next door to them, as it is clearly and distinctly blotched with a most beautiful cream-coloured variegation, which seems very constant, and renders the plant likely to prove a great acquisition to our ornamental shrubs. A distinction should, I think, also be pointed out which exists between the two variegated forms of the golden variegated Golden Tree (*Liriodendron tulipiferum*), only one of which is mentioned in the list in question. This, however, seems from its description to be by far the most beautiful and distinct of the two, and was sent out by M. Van Houtte two or three years ago under the name of *Liriodendron tulipiferum aureo-marginatum*, being well figured in vol. xx. of the "Flore des Serres," t. 2801. The other, a decidedly inferior variety, which can be had at less than a quarter of the price of the above-named, is correctly named *Liriodendron aureo-vittatum*, being only more or less sparingly blotched with gold. W. E. G.

Hæmanthus cinnabarinus.—This is one of the rarest, and, when well grown, most gorgeous of all bulbous plants, and as such is deserving of more extended cultivation in our gardens. It is a native of the western coast of the African continent, and has, on one or two occasions during the past year, been exhibited by Messrs. Jas. Veitch and Sons, of Chelsea. The Hon. and Rev. J. Townshend Boscawen, of Lamorran, Probns, has also been most successful in its culture. The inflorescence is frequently more than 18 in. in circumference, and of a vivid, cinnabar-scarlet colour, tinted here and there with carmine; indeed, scarcely any illustration could well represent the colours, since they have the sparkle and lustre of a Guernsey Lily, or some of the glowing *Masdevallias* of the M. Veitchi or M. ignea type. Mr. Boscawen had fertilized some of the flowers, and the seed-vessels had begun to enlarge ere the spike was cut, so that it seems probable that it may be increased by seeds. There are several other remarkably beautiful species in this genus well worth more general culture, but none better than the plant now alluded to since, apart from its value as a somewhat stately-habited stove plant, its star-shaped flowers and coral-tinted buds are admirably adapted for mixing with pearly white *Eucharis*, Lily of the Valley, or other choice bouquet flowers. Its season of blooming varies under cultivation from March to November, and it continues fully six weeks in bloom.—S.

Hybrid Fuchsia (Earl of Beaconsfield).—This is one of the most floriferous of all the modern hybrids in the graceful genus to which it belongs, and has been obtained by Mr. John Laing, of the Stanstead Park Nursery, Forest Hill, its parents being the old *F. fulgens* (now rarely seen except in country cottage windows), and one of the modern florists' varieties, grown under the name of *Perfection*. It is both distinct and attractive, and likely to be much sought after, not only as a permanent ornament in conservatories

and corridors, but also as a plant well suited for pot culture for markets. The plant is of a dense pyramidal habit, branches freely, and each shoot is terminated by a raceme of carmine and cinnabar-tinted flowers and buds contrasted with ample foliage. The plant has received a first-class certificate from the Royal Botanic Society as being eminently suited for decorative purposes. Fuchsias are always graceful and attractive, but never more so than when trained up the rafters of a moderately warm conservatory, and allowed to hang from the roof in pendent festoons of flowers and foliage. They are so grown at Kew, in the Camellia corridor at Chiswick House, and in the conservatory at Hatfield, and nowhere have we seen the beauty of these plants to greater advantage. The luxuriant and floriferous habit of the plant would seem to render it especially suitable for such positions, apart from its extensive culture in pots.—B.

AN IMPROVEMENT IN WHEELBARROWS.

THE wheelbarrow, it is said, was invented by the eminent Italian artist, Leonardo da Vinci. That it was the production of so capable a man is possibly the reason that it has remained for centuries unaltered, and considered so far incapable of improvement. Nowadays, however, our wants are so many and our wishes so exacting, that for some uses the present wheel-

A new Wheelbarrow.

barrow is not satisfactory. In the garden the wheelbarrow is very useful even in its ordinary construction, but in the shape in which it is presented in the accompanying illustration it will be still more useful. The additions and improvements here described are the result of the ingenuity of Mr. Beach, of Hartford, Connecticut. They are as follows:—A rubber wheel-tire, by which more quiet and easy rolling is secured; two springs fitted to the axle, which prevent jolting; a wheel-lifter, or a second pair of longer legs, by which it may be lifted over obstructions by pushing forward the leg-frame and bearing down upon the handles; a movable water-pail hook; drawers for seed, &c.; a seat with a socket for an umbrella or sunshade, to be used while resting; four buckled-strap loops for holding tools; four partitions for various uses; two sliding doors for quickly emptying it of its contents; four baskets fitting into the partitions; and lastly, a movable cover made to fasten by a latch or catch. Each and all of these may be removed at will, except the rubber-tire. Some of these appliances will be found useful for any wheelbarrow, and others are intended for special work in the garden and orchard, where one wishes to have all the tools he is likely to need at hand in a convenient manner. It is really converting a wheelbarrow into a portable tool-house. Mr. Beach writes us ("American Agriculturist") that he has spent three years in perfecting his wheelbarrow, but that he will be sufficiently repaid if the public appreciate his invention.

THE KITCHEN GARDEN.

ASPARAGUS BEDS IN CLAYEY SOIL.

ASPARAGUS, besides having the great merit of bearing for a long season, can be had in good supply over six months in the year, by commencing to force in November, so as to cut the first dish for Christmas. Our forefathers considered it necessary to take as much care in preparing Asparagus beds as they did a Vine border; yet, although its culture is so simple, I do not think that the cultivation of any vegetable is so little understood by the majority as that of the Asparagus. Some look upon its culture as a mystery, and never make an attempt, while others, from the costly preparations they are given to understand it requires, and the uncertainty of success, abandon the idea of cultivating it; but these fallacious ideas may all be dispensed with, and the amateur may cut as good a dish of Asparagus as the professional cultivator, if he will but give a slight amount of attention to its preparation in the different seasons.

Asparagus requires a good depth of soil and plenty of manure; where the soil is shallow, waste sand or any other open material may be mixed with it. When I first came here, I found the garden without Asparagus beds; so I made choice of a sheltered corner, well exposed to the south, and staked out a large square of clayey ground, which I covered with waste sea-sand, that had been used for grinding glass, 2 ft. deep, and on this I placed a good layer of decomposed horse manure; a trench having been formed at one side, the whole was turned over with a good layer of clay thrown on the top to get pulverized for a few weeks, and when this became dry it broke up quite fine, when the whole bed was again turned over and well mixed, and when the sides were squared up the beds stood well up above the ground-level, insuring a good drainage, without which no beds will succeed. This being done in the month of April the alleys were trodden out and the seed sown at once, and no preparation could have been more satisfactory either as regards quantity or quality than these beds have been during the last four seasons. In fact, the secret in high culture is shelter, good drainage, a loose soil, and plenty of good manure.

I prefer sowing the permanent beds with seed in rows 18 in. apart, and as soon as the plants are 3 in. long thin them out to about 12 in. asunder in the row, leaving the most promising; in this way the plants never receive a check and always make up well in the autumn. In planting the beds with one or two-year-old roots April is the best time, when the young sprouts are about 1 in. long—not more (I never cover them more than 3 in. deep), which keeps the crowns strong and healthy and the heads eatable the whole length. During the growing season liquid manure is used by many, but if the beds be well made at first they may be considered self-acting. On the appearance of rain, three or four times in the year I throw a few handfuls of salt over the beds. Asparagus should be allowed to grow in the beds three seasons without cutting, which treatment insures a permanent establishment of the plants, and a good crop may be expected the following season. Great discretion is required in cutting Asparagus, so as to make the season as long as possible. The following is my plan of operations:—Supposing that I have six beds ready for cutting, from three I only cut the finest heads, and leave the remainder to grow, which keeps the roots in action, and strengthens the buds for the following season, but it shortens the succession, and cutting is soon over; the remaining three beds I cut all the heads for the first three weeks, which causes every bud to push and produce a good late crop; in the following season this mode of proceeding is reversed. Any beds that are wanted for forcing the following season, I encourage a good crop of the earliest shoots to grow upon, and after that cut all the remainder to the end of the season, as the early growths make early buds, and the late ones are not wanted, as the roots all go to the refuse-heap as soon as the crop is gathered. Where a quantity of roots is wanted for forcing every year, new beds should be made to take their place; the beds must be covered with littery manure in the autumn to protect the crowns from frost. With regard to forcing, a brick pit or roomy frame on a bed of fresh horse manure or leaves turned over two or three times to

sweeten, or spent tan, answers well for bottom-heat; but the principal agent in producing good heads will be found in strong, well-prepared roots, full of vigour, which have not been cut more than three or four seasons; old worn-out roots never pay for the trouble of cultivation. Well-prepared roots of Asparagus enjoy a bottom-heat of 70°, not more, and as soon as the heads are through the soil, give air as freely as the weather outside will allow, as it bestows both strength and flavour to the plants. Sharp frosty air or cutting winds must be avoided; a good covering on the glass in severe weather is very essential, as it keeps the temperature uniform, which should not be more than 50°. For filling in amongst the roots, nothing is better than some old spent manure, such as has come from the Vine borders, and has been laid for some time previously in a heap; the fibres will then revel in it till the manure becomes quite white, which gives strength to the heads. In giving water avoid liquid manure; a small handful of salt may be put in each can, which benefits the plants without injuring the flavour. JAMES SMITH.

Waterdale.

Smooth-tubered Jerusalem Artichokes.—A correspondent (see p. 486, Vol. X.) speaks of Jerusalem Artichokes as articles of food, and as being unsuited for cultivation by cottagers, on account of their irregular form and the great waste there is in peeling them. I believe this may often be traced to the kind of sets used for planting, which in many cases are nothing more than the refuse of the previous years' crops. If your correspondent will procure a few smooth tubers about the size of hens' eggs, and plant them whole in well-trenched ground, and in lines 3 ft. apart and 1 ft. asunder in the row early in March, and earth up the plants when they are 2 ft. high, he will find, as I have done for many years, that the produce will be smooth-skinned and well-shaped tubers, and by a careful selection of good sets annually, he will be rewarded with heavy crops of excellent Artichokes, of good appearance and quality, without waste.—JOHN CLARKE, *Cork.*

How to Grow Fine Parsley.—Sow the seed towards the end of August in comparatively poor but well-drained soil; and if circumstances prevent such selection, choose the ground which comes nearest to it. It may be sown either in lines where it is to remain, or in seed-beds; but in any case it must be transplanted, for Parsley succeeds much better, and lasts longer in that way than by any other method. It will be fit to transplant in March, and should then be put in whatever positions it is desired it should remain. The plants so transplanted will be found excellent to put into pots and boxes for the winter, as is the rule in gardens where a winter supply of Parsley is indispensable in all weathers, or for any other purposes for which Parsley is used. Edgings of Parsley near a dry walk or alley are desirable for the convenience of picking when the ground is soft and sticky, and will not admit of being walked upon without clinging to the feet, and being thus brought on to the walks.—C. S.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Sowing Early Peas.—In order to gather Peas the last week in May and the first week in June, the following has been my practice for the last thirteen years:—I sow now in boxes, and put them in a cold frame under glass, giving plenty of air at all times. When 3 in. high I plant them out on a warm border, and stick them as the planting progresses. I have this day (Jan. 27) sown Sutton's Kingleader, Dickson's First and Best, and Dr. McLean; the last named is one of the best Peas in cultivation.—R. NISBET, *Aswarby Park.*

—Peas, sown in November, have now tendrils 2 in. long, which makes one almost dread the cold cutting winds which are sure to follow the present mild weather. In the event of frost, what is the best mode of protecting them?—N. F., *Oakham.*

Winter Salad Plants.—Witloof is highly appreciated here for this purpose. We took the roots up in October, and they were treated the same as Carrots. When put into the Mushroom-house the tops soon blanch, and, when mixed with Endive, make a good salad; nor are they to be despised when cooked like Seakale, and used as a vegetable. The Improved Round-leaved Endive has proved the best with us; blanched out-of-doors under small Seakale pots, or placed in boxes in the Mushroom-house for a few days, a good salad may in this way be had by all, even where glass is limited. Owing, doubtless, to the wet, Lettuce plants have done very badly in frames this season.—J. ALLAN, *Ashurst Park, Tunbridge Wells.*

—With me Witloof, Chicory, and Endive are all great favourites. I force and blanch the Witloof in a temperature ranging from 50° to 60°, and I am inclined to think that thus managed the bitterness is less than if it were brought on slower. The Endive is grown in cold houses. I should be glad to know what difference, if any, there is between Witloof and Chicory; they appear as near alike as to be hardly distinguishable. Mr. Gilbert would find a small quantity of Celery improve the flavour of the salad bowl of which he speaks (see p. 56), and with the Tropæolum blooms he should put a few slices of crimson Beet.—N. F. F.

CROCUSES AND MICE.

IN common with other Crocus growers I have suffered sorely from the ravages of mice; they devour my seedlings by potfuls, and my full-grown bulbs by the dozen. The little wretches do not confine their depredations to Crocuses; only a week or two since they devoured a whole potful of bulbs of *Bloomeria aurea*, which I had just received from California, and another of *Brodiaea volubilis*. The house mouse, the long-tailed field mouse, the short-tailed and barb voles, and the common shrew are all, I believe, more or less mixed up in the mischief, the three latter attacking small seedling bulbs; but the greatest depredator of all is the long-tailed field mouse, which abounds in some seasons to a most alarming extent. I once caught seventy in six weeks among my Crocus beds.

My rows of Peas, too, in spring suffer frightfully. Mice are also most destructive pests to the farmer, devouring greedily all kinds of grain. I have not the least doubt that they are far more common than they otherwise would be in consequence of the senseless way in which every species of owl is destroyed. There are four species of owls fairly common in the British Isles—at least they would be so if left alone—viz., the barn owl, the brown owl, and the long and short-eared owls, and all of them live mainly upon vermin—rats, mice, moles, weasels, snakes, &c.—but all are ruthlessly shot down by gamekeepers. All the owls are nocturnal in their habits. The only species which flies in the daytime, and that but rarely, is the short-eared one. At night young partridges and pheasants are safe brooded under their mothers' wings; the owls could not get them if they wished. The brown owl may occasionally pick up a small leveret or young rabbit, but what is that compared with the myriads of mice, young rats, and weasels which it destroys? It is principally, however, in defence of the common buff or barn owl that I take up the cudgels. When I first came to my rectory here my out-buildings were in a very ruinous condition, and I could not afford to rebuild them all at once. My stable had a thatched roof covering a dark loft; through a hole in the thatch a pair of barn owls had free entrance to the loft, and here for several years they regularly reared four or five young ones—in fact, till I was forced to pull the stable down and rebuild it. I have often watched these owls feeding their young ones. For several hours after sunset, every three or four minutes they would bring in a mouse or young rat, or some other kind of vermin. And yet this is the bird ruthlessly shot down by squire, gamekeeper, farmer, and poacher alike, and eagerly bought by every bird-stuffer for the ornamentation of ladies' hats or the manufacture of feather screens. It is unquestionably a disgrace to the country that these things should be permitted. Is there no member of Parliament sufficiently instructed to get an Act passed prohibiting the destruction of the barn owl altogether, and protecting the other three species for the greater part of the year? Upon looking at the schedule of the Wild Birds' Protection Act, I see the term "owl" amongst the rest. Auyhow, it is in this respect a dead letter, and the sooner it is actively enforced the better.—H. HARPUR CREWE, *The Rectory, Drayton-Beauchamp, Trin.*

UNDERGROUND HOT-WATER PIPES.

ALLOW me to offer a few observations on the subject of boilers and underground hot-water pipes with especial reference to Mr. Groom's remarks (see p. 75). It has been my experience, and I find I am not alone, that it is most difficult for amateur gardeners to get any definite information as to boilers and fuel before they have earned their own experience by paying for it. About two years ago I wished to heat a small, very narrow house, some 30 ft. long by 5 ft. broad, and selected for the purpose a common vertical boiler, which I placed in the corner of a coach-house immediately under its work. This boiler heated its quota of 50 ft. of 4-in. pipe fairly well, but the firm from whom I purchased it fitted it with only a 4-in. flue pipe, and the draught was accordingly deficient, and by no possible treatment could I get a coke fire to keep in all night. After a good deal of perplexity I was recommended to use culm instead of coke, and with that fuel there was no difficulty in keeping in the fire from ten o'clock at night to seven o'clock next morning. This heating apparatus would not have been disturbed had I not erected a 12 ft. by 20 ft. span-roofed plant-house some 40 ft. distant from the house already men-

tioned, and I determined to try the experiment of heating both houses with one boiler, although it would have to be connected with each house, owing to the configuration of the ground, by more than 60 ft. of pipe. After a diligent study of the advertisements in THE GARDEN, I obtained the boiler that appeared to me the soundest in principle, and erected it in an outhouse in my stableyard midway between my two houses. It is my firm conviction that in spite of the more than 120 ft. of 1½-in. connecting pipes, the new boiler heats the two houses with the same amount of fuel consumed by the old one to heat the one house. The design of the vertical boiler is simple in the extreme, so simple, indeed, that a great deal more heat passes up the flue than into the water-pipes; the new one is so constructed that the fire heats the water instead of performing any other less desirable function. The old one was fastidious as to fuel, the new one scarcely keeps itself supplied with ashes sufficient for banking, as it clinkers everything. Then, as to the saving of time and trouble, the fire is left for the night during ordinary weather at five o'clock, and a good fire is found burning at half-past seven next morning. By way of experiment I had, some weeks ago, the fire banked up at nine o'clock one morning to see how long it would go; that fire was not touched until after seven a.m. the next morning—more than 22 hour; the boiler was then heating only 50 ft. of 4-in. pipe, and the difficulty was to keep in for so long a time a sufficiently small fire. There is no doubt that long connecting pipes waste a certain amount of heat, but seeing the vast amount of heat wasted in the best boilers by the draught necessary to produce combustion, the heated air being a total loss after it passes out of the boiler, I think the connecting pipes must be very long and very badly fixed to turn the balance of heat-saving in favour of a second boiler with a second heat-wasting flue. The old boiler, so simple in its design, and so wasteful in its work, has been erected in my cellar, where it occasionally heats with a new 6-in. flue-pipe about 40 ft. of piping in a conservatory some 15 ft. distant, and a coil of 40 ft. more in my entrance hall—through about 80 ft. of 1½-in. pipe, including flow and return. As a continuous fire is not needed, and the boiler can get attention when required, it answers the purpose, there being no lack of heat generated; but if ever it breaks down I shall certainly study THE GARDEN advertisements once more and look out for a boiler combining economy in fuel and strength in construction rather than simplicity of design, which can scarcely be obtained without corresponding loss of heat. I may say, in conclusion, that I have not a particle of coke on the premises.

A. R. H.

NOTES AND QUESTIONS—VARIOUS.

Early Broad Beans.—The earliest and best long-podded Bean is the Seville; it is four or five days earlier than Early Long-pod, and I grow it for my earliest crop.—W. G., *Bradford, Dorchester.*

Opuntia vulgaris Hardy.—This plant is quite hardy in the Paris Garden of Plants, where it has spread into a wide, vigorous tuft. It seems a somewhat stronger grower than *O. Rahnesequiniana*. The plants are protected with a wire cage to prevent injury to the succulent leaves, which otherwise would be in danger of disfigurement in a crowded garden.—V.

Premier Runner Bean.—What is the experience of cultivators in regard to this Bean? I was induced last year to try it, but I must admit that it proved worthless. Instead of sowing my usual quantity of the Scarlet Runner I sowed two-thirds Premier with the result just stated, while the Scarlet Runner by the side of it bore, as usual, a good crop.—R. B. FULLER, *Highbury.*

Veitch's Self-Protecting Autumn Broccoli.—"J. W." (see p. 68) wishes to know at what time I sow this Broccoli, as with him it does not come in at the same time as with me. Allow me to state that I sow in the second week in April in the open border, in which the plants succeed perfectly, with two or three good waterings about planting-out time should the weather prove dry. Mine were planted on a south border.—W. G., *Bradford, Dorchester.*

Ficus repens in the Open Air.—As in various cases about London, *Ficus repens* has crawled out of one of the houses in the Paris Garden of Plants, and covered the adjacent walls in all directions. This proof of hardiness is, however, scarcely wanted, as in Colonel Turbe's garden at Woodstock, in Ireland, it has long been a vigorous wall plant. It would be well to know if the more delicate and graceful creeping Fig (*F. minima*), introduced by Mr. Hogg from Japan, is also hardy; if it prove so, it will be a pretty addition to the rock garden and hardy Fernery.—V.

Propagation of Double Primulas.—Few plants are more useful than Primulas, more particularly the double kinds. We have just now (Jan. 27) plants of them in full bloom which have been in that condition ever since last October. We strike them now and onward until May. We divide the crowns, taking care to secure to each piece a heel, and then put in single thumb-pots, which we plunge in heat under hand-lights. The secret of success is to give no water until they are struck.—R. GILBERT, *Burghley.*

Royal Aquarium, Westminster.—Mr. Bennett, of the Rabley Nurseries, Shenley, Herts, has been appointed to succeed Mr. Wills as floral director of this institution. Several alterations as regards the floral display are contemplated, and amongst others the permanently-planted side beds, already alluded to in our columns as being so difficult to maintain in health, are to be done away with. The floral display in this part of the building will, however, continue to be carried out in the shape of ornamental, rustic, and fancy wire designs, the idea being that in this way more variety of colour and a larger quantity of blooming plants can be introduced than heretofore.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

SOME OF THE PRESENT ASPECTS OF GARDENING.

Nothing is immutable, nothing stationary; nor is this a subject for regret, for without changes there can be no progress. Judging from present appearances, there are not wanting signs that in ornamental gardening the bedding system, as it has been called, has passed its zenith, and that there is a prospect of its being reduced at no distant day to reasonable limits; in fact, in many places, reductions have already been made, to the satisfaction and advantage of all concerned. I admit that the bedding system has, in a certain sense, given an impetus to gardening, but in far too many places it has been at the expense of other and more important matters. A writer in "The Gardener" for January last says:—"There never was a time when so many places were to be met with in a half ruinous condition as now, weeds in many cases overrunning the less than half-cropped ground in kitchen gardens;" this, he adds, "may be seen in the majority of places in every county"—a result, doubtless, either directly or indirectly traceable to the undue prominence given to carpet and other beds of a similar character, so extensively used for summer decoration. Vegetable and fruit-growing have had to be neglected from the sheer impossibility of getting through the work. Vineries and Peach-houses have been so filled up with bedding plants during winter and spring, as to almost preclude the necessary attention being given to the inside borders. And after all, what good has been effected beyond encouraging a vitiated taste for lavish display? A constant repetition of the same designs, planted with the same materials, has destroyed all individuality as regards independent thought or action, and has had a baneful influence upon the cultivation of all plants that could not be turned to account in the way of brilliant display. The future, however, is full of hope that this state of things will be altered, at least to some extent, and in that case the culture of fruit and vegetables will doubtless receive increased attention, not merely for the purpose of astonishing people at exhibitions—although it is well to have the best results of our labours frequently set before us—but rather to supply abundance of fairly good produce for daily use at home. Summer flower gardening, however, need not be wholly dispensed with; on the contrary, a few beds tastefully planted, properly situated, and thoroughly well managed, have always a striking effect during favourable weather in July and August; it is the too prevalent tendency to cut up every bit of green turf into stars, diamonds, and similar devices, and to encircle every bit of shrubbery with ribbon borders, that is so much to be deprecated. There may in some gardens be architectural features in connection with the mansion that will not bear reduction; these must remain, but in the majority of cases no such necessities exist. Where the design, from its intricacy, will not bear reduction without destroying its proportions, it is best to wholly discard it, and lay down a few plain, simple figures of a size proportionate to the place. I always think flowers look best on cool, green turf; and how easy it is when the designs are laid down on a turf base to effect an entire change. A large garden may, in the matter of brilliancy, eclipse a small one, but size or extent is not essential to beauty, although, in a certain sense, it may be to magnificence.

There is, perhaps, no department in gardening more important, or that requires more knowledge or judgment than the selection and arrangement of the trees and shrubs that are to form the permanent adornments of the home grounds; not only is a thorough acquaintance with the soil necessary, but also a full knowledge of the life history of each species which it is intended to plant, in order to secure the necessary conditions to obtain a successful result, and it is probably due to a lack of this knowledge that cultivators still continue to make use of only the commonest trees and shrubs that have been proved to flourish in any soil or situation. This is to be regretted, for the trees and shrubs form what may be

termed the outside furniture of the residence. Other features, such as beds of flowers, come and go, but the trees and shrubs are permanent, and, viewed in this light, the subject is deserving of more consideration than it receives. In far too many places the shrubberies are simply eyesores. There are positions in which a tangled thicket may be appropriate enough, but near the mansion, or in juxtaposition to the overwrought masses of flowers, thickets consisting of common-place materials produce an incongruous effect. In the majority of cases it would not cost much to make openings here and there in uninteresting, monotonous blocks or masses of plantation, and introduce some of the better kinds of deciduous and evergreen trees and shrubs. Of course some pains must be taken to give them a fair start; all old roots must be grubbed and picked out, and a little fresh, loamy soil, if possible, brought in which to plant them. Many of the hardy trees and shrubs introduced during the last thirty years would even, if sparingly planted, quite alter the character of our garden scenery. Of course, in some places there will be difficulties to contend with; trees and shrubs have their peculiarities like all other living things; some will only flourish on the side of a hill where the drainage is free and rapid; others again delight in moisture, or require to be sheltered from the keen biting blast. But the best kind of knowledge comes by experience, and how interesting it is to watch the annually increasing beauty of a handsome young specimen tree or shrub when it has room for a fair amount of development, so as to show its true character! Such subjects are capable of giving far more interest and satisfaction than can ever be obtained from beds of Pelargoniums or of similar plants, showy though they may be. There is, too, a steady demand springing up for old-fashioned plants and flowers, and in connection therewith we can have our rock garden, which can either form a part of the wild garden, or be a distinct feature artificially created. Rockwork should not, however, be placed under the windows of the mansion, but should be erected in a retired spot, where the surface is naturally uneven. The most perfect rock garden which I ever saw was one hewn out of the natural rock; it was approached by steps and winding walks, disclosing fresh objects of interest at every turn; and the almost perpendicular and sometimes overhanging rocks were richly draped with creepers. The hand of time had also covered the rough faces of the stones with Mosses and Lichens, which, to the student of Nature, had an interest of their own apart from the choice gems gathered there from Alpine regions, and which were cultivated in pockets and nooks. Among the stones and their decaying débris, with compost added suitable for each species, many classes of hardy plants may appropriately find a place in a rock garden or in its immediate neighbourhood, and there should be a tank or basin for aquatic plants, in order that plant-lovers of all kinds might meet there as on common ground, sure of always finding something to interest and instruct.

E. HOBDAV.

Hardy Wall Shrubs at Kew.—The single-flowered *Kerria* (*Corchorus*) *japonica* is now in beautiful condition on a wall in the herbaceous ground at Kew, its leafy autumnal shoots being studded with golden star-shaped flowers. Close beside it a vigorous specimen of the Himalayan *Berberis* (*Mahonia*) *nepalensis* is very attractive, its tufts of thick, glaucous, pinnate foliage being surmounted by large panicles of yellow flowers. The Whitewashed Bramble (*Rubus biflorus*) is even more interesting now than during the summer, but its bare white stems, as seen against the brickwork, are not nearly so attractive as when contrasted with Ivy or other evergreen wall shrubs. *Cydonia japonica* is, of course, covered with rosy-scarlet flowers and coral-tinted buds, and a plant of the orange-scarlet-berried *Solanum pseudo-capsicum* has quite a fresh appearance on the open wall, and is bearing a few berries. Two of the most beautiful and desirable of all the wall plants at Kew are *Phygalea capensis* and *Veronica Andersoni*, the latter being still attractive, as are also the golden and silvery-leaved varieties of *Eunonymus* on the sunny walls of the Economic-house. *Solanum jasminoides* always flowers well on the wall of the herbaceous ground, and it ought to find a place in all sheltered London gardens. In some of the villa gardens near Kew railway station it may be remarked that excellent use is being made of the common *Laarustina*, the white flowers of which are judiciously contrasted with the scarlet-berried *Skimmia japonica*.

B.

NOTES OF THE WEEK.

IRIS RETICULATA PURPUREA.—A bed, planted with this winter-flowering Iris, may now be seen in Ware's nursery, Tottenham, studded with bright purple, orange-streaked blossoms. When grown in rich, well-drained, sandy soil, as it is here, this is undoubtedly one of the most valuable hardy, early-flowering bulbs which we possess. In pots it would also be found useful for the decoration of the conservatory for a few weeks in midwinter.—C.

FORCING THE WHITE LILAC.—It is pleasant just now to enter one of the houses devoted to the forcing of White Lilac in Paris, the delicate odour of the opening blossoms pervading the darkness. The plants are placed on pots and benches, kept warm and moist, and the glass covered with straw mats, so as to keep the house quite dark.—V.

NEW DOUBLE CHINESE PRIMULA.—This is now in flower at Pine-apple Place, and seems likely to prove an acquisition. Its flowers, which are large and double, and of a rose-lilac colour, margined with white, are produced in whorls on vigorous stalks that rise well up above the leaves, which are elegantly cut. It is named Miss Eva Fish.—M.

ODONTOGLOSSUM CRISPUM.—A fine plant of this lovely *Odontoglossum* growing in a cool house at Leyton is now bearing five or six strong flower-spikes, on each of which are from nine to twelve large fully-expanded blooms. Mr. Ward asserts that he has never seen without flowers of this Orchid either winter or summer during the past four years. Plants of this description can scarcely be too extensively grown or too highly prized, when we consider that any one who possesses a warm, moist greenhouse may grow them successfully.—C.

THE JAPAN QUINCE IN GROUPS ON THE GRASS.—One of the prettiest effects now to be seen in the gardens of Paris is a little colony of bushes of the Japan Quince (*Cydonia japonica*) irregularly grouped on the Grass near to, but quite free from, the margin of a shrubbery. This is one of the ways in which our beautiful hardy flowering shrubs may be best enjoyed—one of the alternatives from the dismal system of crowding everything together.—W.

ROGIERA GRATISSIMA.—This seems to be as scarce in gardens as *Luculia gratissima*, notwithstanding the fact that it is much more easily managed. Several well-grown specimens of it in the gardens at Wimbledon House are now loaded with blossoms, which are borne in large trusses similar to those of *Habrothamnus elegans*. The *Rogiera* is, however, not quite so rampant a grower as the *Habrothamnus*, and its flowers are deliciously scented.—S.

FICUS LANCEOLATA.—This forms a good companion to the well-known India-rubber Tree, so useful in large towns for window decoration. *F. lanceolata* which is a somewhat more compact-growing plant, has long, narrow, lance-shaped leaves, graceful in appearance, and will stand smoke and dust equally as well as those of *F. elastica*. Mr. Reeves, of Acton, who has quantities of it, expects to find it one of his best market plants.—W.

IRIS STYLOSA AT KEW.—A strong tuft of this evergreen winter-blooming Iris is just now in flower in the long herbaceous border at Kew, where it bears some ten or twelve fully-expanded blossoms. It is one of the largest-flowered and most ornamental of all Irises, and it may be added that blooms of it cut in the bud state open well and retain their beauty for two or three days in a glass of water.—B.

A GRACEFUL INDOOR CLIMBER.—*Clematis indivisa* is now beautifully in flower in the greenhouse at Kew, where it covers a rafter 15 ft. or 16 ft. in length, its drooping leafy branches being thickly studded with star-like flowers of snowy whiteness. Each six-rayed blossom is the size of half-a-crown, and being freely produced among glossy leaflets, the effect is excellent. As a climber or wall plant for a cool greenhouse this *Clematis* has few equals at this season, and it would doubtless succeed out-of-doors in the mild climate of Devon, Cornwall, or the Isle of Wight, where it would be found useful, flowering, as it would probably do, a month or two before its four-rayed ally, *C. montana*.—B.

HARDY FLOWERS IN THE ISLE OF WIGHT.—The following, gathered from my garden at Bonchurch to-day (Feb. 7), will serve to show what our climate has been this winter. Among them will be found several beautiful forms of *Narcissus tazetta*, hardy Heaths, *Gazania splendens*, Clove Pinks, *Cytisus racemosus* and its near ally *Coronilla glauca*, Persian Cyclamen, *Cliantus panicus*, Mignonette, and a lovely bloom of General Jacqueminot Rose, together with Stocks, *Anemone coronaria*, Purple Mesembryanthemum or Fig Marigold, *Vinca major*, and the ever-blooming *Veronica Andersoni*, one of the most floriferous of all sea-side shrubs. The General Jacqueminot

Rose is from a plant trained in a south aspect, but the Clove is from quite an exposed situation; the *Cliantus* grows against a wall facing the east. I have never seen during fifteen years' experience in the garden here so many plants in blossom so early as we have this season.—J. BANTING.

DENDROBIUM CRASSINODE AT KEW.—A specimen of this delicately coloured species is just now the most attractive of all the Orchids in the Kew collection. It bears about forty pure white, carmine-tipped flowers on four of its thick knobbed pseudo-bulbs, and seen in this condition it is certainly one of the most beautiful of all *Dendrobes*.—S.

ANTHURIUM SCHERZERIANUM ALBUM.—This white-flowered form of a well-known and extremely ornamental stove plant is now blooming abundantly with Mr. Ward at Leyton, and although it is questionable whether it will ever become so universal a favourite as the scarlet-flowered kind, yet the two intermixed are strikingly effective.—C. S.

FERULAS AT TOTTENHAM.—These are planted at Ware's on a large earth-mound, which their bright green and feathery-looking foliage completely covers. They commenced to push through the ground late in autumn, and all through the winter have formed an interesting feature amongst hardy plants.—P.

DENDROBIUM EUDOCHARIS.—This new hybrid *Dendrobe*, raised by Messrs. Veitch & Sons, is now flowering freely in their nursery at Chelsea. Its flowers are of the purest white with a yellow and purple-tinted throat; it is a cross between *D. japonicum* and *D. heterocarpum*, and partakes of the strong-growing habit of the latter. It will doubtless prove a useful addition to winter-flowering Orchids.

HONEYDEW IN PLANTS.—Dr. Hoffman, of Giessen, has recently published the results of his observations on the formation of honeydew upon the leaves of plants, and has come to the conclusion that it is not to be attributed to aphides or other insects. A healthy *Camellia*, 1½ ft. in height, without blossoms, which afforded an instance of the phenomenon, was found to be entirely free from insects. The so-called honeydew consisted of a sticky, colourless liquid, which possessed a sweetish taste, and contained, principally, gum.

GARDENING IN VICTORIA.—The returns for 1874-5 show 11,083 acres under gardens and 6317 acres under orchards, as against 9912 acres under gardens and 6148 acres under orchards in the previous year. Ten acres under Olive trees and 6 acres under Mulberry trees were recorded in 1873-4, but no Olive grounds, and only 1 acre under Mulberry trees, appear in the returns of the year under review.

NARCISSUS TAZETTA FLORIBUNDUS.—When in Cornwall a few years ago I obtained some of the roots of the white-limbed yellow-corollaed *Narcissus tazetta floribundus*, which grows so freely at St. Michael's Mount and elsewhere. These roots always throw up their flower-stems before Christmas, but are usually destroyed by frost; this year, however, I have a fine clump in exquisite bloom still continuing to throw up flower-stems. In the extreme south surely this early-flowering plant might be grown profitably for its flowers, which might be gathered and sent to market in quantity. Spring-flowering plants are plentifully in bloom, but I have nothing more charming than this *Narcissus*.—L. C., *Sydenham Hill*.

DOUBLE-FLOWERED PEACHES.—Few plants used for forcing are more effective when in flower than these, yet they are comparatively seldom met with in ordinary gardens. In a cool house at Kew may now be seen many varieties of them, consisting of white, pink, and rose-coloured kinds, the leafless branches of all of which are thickly set with bloom. The plants range from 6 ft. to 8 ft. high, and from 2 ft. to 3 ft. through, and contrast well with the numerous kinds of ornamental-foliaged and other flowering plants with which they are associated.—S.

HARDINESS OF CRINUM CAPENSE.—Both the forms of this handsome Amaryllid, alluded to by Colonel Trevor Clarke (see p. 51) are quite hardy in the open border here (Wigtonshire), and flower freely every year. It never occurred to me that they should be treated as aquatics; they grow luxuriantly in deep but well-drained peat, occasionally getting a bucket of water in summer. The price is very much less than your correspondent mentions. The Dutch nurserymen quote them at 5d. each for the rose and 9d. for the white, and they are well worth importing. As the bulbs are very large, the base of each should rest 1 ft. under the surface. The foliage is bold and ornamental, but if the plants be in a small garden or near a window it is a good plan to plant *Commelina cœlestis*, *Nemophila insignis*, *Lobelia cardinalis*, or other graceful bright flowers round the *Crinum*, at a distance of 2 ft. or 3 ft., which come up through the long leaves and form a beautiful group.—H. M.

HARDY FOLIAGE FOR LARGE VASES.

At this season of the year some little difficulty is often experienced in obtaining foliage—and especially hardy foliage—for arranging in large stands and vases along with cut flowers. In sheltered positions the common Hart's-tongue (*Scolopendrium*) and Hard Ferns (*Polystichum*) still furnish fresh and somewhat stately fronds, admirably adapted for such purposes; and as a contrast to their vivid greenness, I can find nothing at all equal to the young silvery leaves of the Globe Artichoke, which I highly esteem as a fine-foliaged plant, even in shrubbery borders and wild gardens grouped with *Ferulas* and other early-growing fine-foliaged Umbellifers. Leaves of the Artichokes may be selected of various sizes from 9 in. to 2 ft. in length, and, apart from their delicate glaucous or silvery tint, their gracefully arched contour is an additional advantage. I have now foliage of this plant quite fresh, after having been cut for three weeks and used for several relays of flowers. I have placed the small leaves or points and sprays cut from the larger ones in shallow dishes of early blooming Crocuses, Snowdrops, Violets, *Iris reticulata*, *I. stylosa*, and *Hellebores* of various kinds, and I find that in this way the arrangement is far prettier than when exotic Ferns are employed. Some of the larger leaves in a tall vase look well wit' a drooping fringe of the common Ivy

The Artichoke as a Fine-foliaged Plant.

around the sides, and here and there a few clusters of the coral-berried Gladwyn Iris. A duplicate vase is filled with Ivy spray and Iris pods, a long-stemmed flower of the white Arum Lily being inserted amidst the green-leaved Ivy. The annexed illustration shows the general effect of the silvery-leaved Artichokes as seen at this season; and of all hardy fine-foliaged plants this must be regarded as one of the most distinct and useful during the winter and spring months. B.

Cordyline vivipara Hardy in Ireland.—This species of *Cordyline* has proved perfectly hardy in the south of Ireland during these last two years. Last autumn twelvemonths I had a basket of it, which was very badly infested with mealy bug, so badly indeed that I determined to throw it away, which I accordingly did. The place where it happened to be thrown was immediately in front and partly under a Laurel hedge which surrounds the frame ground. Here by chance it remained undisturbed all through the following winter and spring, and I was certainly surprised to see it show signs of life in the ensuing May. Although it must have been frozen during the winter, early in the month just named it began to send out shoots from the old ball, these, as they advanced, fastening to the adjacent shoots of the hedge from which they hung very gracefully. The plant continued to grow vigorously all through the summer and autumn, and up to the present time it is looking perfectly healthy. I should have stated, however, that as soon as I noticed signs of life in it I had some soil placed around the ball, but otherwise it was in no way disturbed. So satisfied am I of its hardiness that in the coming spring (about the end of April) I purpose planting out several clumps of it permanently in different positions. I agree with Miss Hope (see page 61) that the stove is not the most suitable place for it, but it is admirably adapted for hanging baskets in a conservatory; this combined with its utility as a room plant, should render it a general favourite.—E. R. Q. P.

THE PARTRIDGE-BREADED ALOE.

(A. VARIEGATA).

THIS handsome, early spring-flowering plant, is so interesting, both as regards foliage and flowers, that special attention ought to be directed to it. It is a hardier plant than is generally supposed, for in my cold greenhouse it invariably gets frozen during very severe weather, but then I always keep it very dry during the winter in common with other succulents with which it is associated. It is a singularly strong-rooting plant, and when well established throws out numbers of suckers at the end of a long vascular growth, which frequently cannot be detached from the parent plant without taking it out of the pot. These suckers, if potted off singly in small pots, soon acquire a considerable size if kept in a warm, moist place for a time. A suitable soil for it is one made up of sandy loam and a fourth part of dry mortar beaten up into a rough powder. In order to increase its size stove treatment is requisite, after which, to secure a good head of bloom, it should be transferred to an ordinary greenhouse. If required to flower, the plant must be strong and richly clad with succulent leaves, which in a good plant are handsomely marked. My best plant is in a 24-sized pot, which it has occupied for two years without change, and as it is in a perfect state of health it will not be necessary to shift it: it produces every year three or four fine spikes of flower. It is probable that if the plant had full exposure and a dry period during July and August, and afterwards a sunny shelf in a stove, with a fair supply of water, it would produce a larger quantity of flowers than when grown entirely in a cold greenhouse. It is an excellent window plant, inasmuch as its thick fleshy leaves may be scrubbed with soap and water to get them clear of dust without injuring them. It will bear great exposure to sunshine, and it may be kept dry for a considerable time without injury. It is a plant that should be distributed amongst the denizens of thickly populated cities and towns by those interested in promoting window gardening, for, as far as its foliage is concerned, it is as pleasing in character at midwinter as at the height of summer; and it appears to be as little affected by damp as it is by sun-heat and drought. D.

Hedychium coronarium and its Culture.—It is to be regretted that this beautiful stove plant is not grown more extensively. The little trouble entailed in its cultivation, and the freedom with which its flowers are produced, together with their delicious fragrance, should render it a universal favourite; nevertheless it is seldom seen even in good collections. Let a plant of it be procured now and started into growth. A soil consisting of equal parts loam, leaf-mould, and dry cow manure, with a liberal addition of silver sand and charcoal broken fine, will be found to suit this plant perfectly. The size of the pot used must of course be regulated by that of the rhizome to be potted, but as a general rule it is safest to employ a rather small-sized pot in proportion to the size of the root, as there is in that case less danger of the soil becoming sodden before the plant starts into active growth. I need scarcely say that when dormant water should be applied with caution, but when once growth has fairly commenced, too much can scarcely be given. During spring and summer it should be shifted into larger pots as may be required, but at all times be careful to supply plenty of drainage. As the autumn advances it should be induced to go to rest, by placing it at the coolest end of the stove, and gradually withholding water, and in this dormant state it should be wintered. If properly treated during its season of growth, the advancing heat in spring and summer will be sufficient to induce it to flower. A temperature of 55° will suit it in winter, and one ranging from 60° to 80° during its period of growth—the former to be accompanied by a dry atmosphere, the latter [by abundance of moisture. This *Hedychium* may be readily increased by division previous to being started into growth in the spring. *H. maximum* and *H. Gardnerianum* are also species well worth growing: the former bears white flowers similar to those of *H. coronarium*, but is a stronger grower; the latter produces yellow flowers and is also a strong grower; the flowers of all the three are deliciously fragrant. The treatment recommended for *H. coronarium* will be found to suit all the other species.—E. R. Q. P.

Rose Garden.—I am just now engaged in remodelling our Rose garden, and should like the opinion of some good rosarian as to the advisability of planting stock rather than worked Roses, budding them of course next summer.—R. GILBERT, *Burghley*.

THE FRUIT GARDEN.

LARGE v. SMALL-FLOWERED PEACHES.

At this season of the year Peach-houses form one of the most attractive sights in the fruit-forcing department, not only on account of the individual beauty of the blossoms, but for the promise of an abundant harvest of fruit which they usually present, for under glass few plants that are grown for their blossoms alone can rival the Peach in the abundance of its floral wealth, which frequently presents a difficulty in the way of pruning by the absence of growing or wood buds to which it is desirable to prune. To a casual observer the large-flowered section, of which the Noblesse is a prominent type, always presents the most inviting aspect; the petals, being large and showy, seem to denote a much more abundant crop than an equal number of flowers on the small-flowered section, of which the Violette Hâtive and Stirling Castle are well-known and highly-esteemed examples. Yet I have observed on many occasions, more especially in early forcing houses, that the small-flowered section set much more freely than the large, the pollen being usually much more abundant; in fact, the pollen of the small-flowered section is more relied upon for setting the large ones than their own pollen. Some difference of opinion exists as to the merits of what may be termed the dry and wet methods of treating Peaches and Nectarines when in flower; I adopt the former and am well satisfied with the results, but probably all other points being equal, the same amount of success would attend either method if skilfully applied. In selecting varieties for a house intended for early forcing, precedence should be given to free-setting kinds of robust habit like the small-flowered varieties named above, as they cannot fail to give satisfaction; for although I consider the Noblesse and similar large varieties excellent as midseason or late-house varieties, they are by no means so satisfactory for early forcing. There are many new varieties highly recommended for early work, but at present I cannot speak confidently of their merits. Amongst the large-flowered section there are few that excel the Grosse Mignonne, either for the quantity or quality of its produce. There is one advantage in forcing Peaches which does not attend the culture of many subjects under glass, viz., the health and well-being of the trees are more generally insured than in the case of those in the open air. Of course an excessive and unseasonably early forcing will eventually destroy any plants, but as a rule Peach culture under glass is one of the most successful in fruit-forcing generally. My impression is that the thorough ripening of the current year's wood is the primary cause of success under glass, and a want of it is the forerunner of most of the evils from which trees grown on open walls eventually suffer.

Henham,

JAMES GROOM.

LATE GRAPES.

I DIFFER from Messrs. Grieve, Wildsmith, and Fish upon some points in regard to these, but especially as to placing Lady Downe's first in order of merit among late-keeping sorts. As a cultivator of Grapes for the last twenty-five years, I have found nothing yet to surpass Gros Colman. I place it first in my list of late-keeping black Grapes for three reasons, viz. — (1) size of berry; (2) size of bunch; (3) for duration or long-keeping qualities; and the late Mr. W. Leaf, of Park Hill, Streatham, considered it first in point of flavour in the class specified above, and he was an authority and a connoisseur in Grapes. Next to Gros Colman, I place Alicante; it is what cultivators term a good feeder, easy of culture, sure to bear a crop—more certain perhaps than almost any other Grape, not excepting Black Hamburg. With me it is always first-class in colour, keeps better than Lady Downe's, which has a tendency to shrivel; it is a well-shouldered, good-coloured, long-keeping kind. I place third Mrs. Pince's Black Muscat, a Grape which has hitherto had but a partial trial. In the class in question it has no equal in point of flavour. I have cut many bunches of this delicious Grape in January, but it is not so certain as the foregoing in point of crop, which is an important consideration with those cultivators who have but a small house and a large demand to supply. I place fourth Lady Downe's, which is inferior to the last-named in flavour and size of berry and bunch. Madresfield Court I could not classify in this list. The accompanying Table may possibly more fully

explain the respective positions in which I place these Grapes:—

	Flavour.	Size of Bunches.	Size of Berry.	Colour.	Quantity.	Keeping Qualities
Gros Colman ...	1	1	1	1	1	1
Alicante	2	1	1	1	1	1
Mrs. Pince	1	1	1	1	2	2
Lady Downe's ..	1	2	2	1	-	1

J. PEED.

Pruning Gooseberries.—Many complain that birds strip the buds off their Gooseberry bushes, and on making inquiries it usually turns out that the bushes have been pruned about Christmas, and in some cases even earlier. This may be termed courting disaster. We never prune here until the bushes are bursting into leaf, and yet we always have heavy crops. It is a good practice to get work as forward as possible during the winter; but some discretion should be exercised as to the right and wrong subjects to be dealt with, or more harm than good may ensue. As regards keeping bullfinches from destroying buds, the best remedy is powder and shot. All kinds of guards except clove netting are useless.—J. GROOM, *Henham*.

Forking amongst Strawberries.—An old Strawberry-grower is scarcely just in his remarks (p. 86) concerning this practice as recommended by Mr. Baines, as the latter was careful to say that "with the exception of loosening the ground to let the rains in, the less digging the better." Mere surface-forking, however, as recommended by Mr. Baines, can be productive of but little injury to Strawberry plants. It is obvious that, during the fruit-gathering time and the after-cleaning off of weeds and runners, that the soil between the plants must get exceedingly hard, especially in the case of stiff soils. Now admitting that in the work of forking a few of the surface-roots are disturbed, do not the remainder and the entire plant generally derive great benefit from the admission of warmth and air to the soil? Still farther, does not the top-dressing of manure, on which your correspondent lays so much stress, get more speedily incorporated with the soil, and consequently food for the roots, than if the surface remained hard and unbroken? And if a few roots be injured, how many fresh ones are thereby induced to grow?—A. DEAN.

—"R. S. C." asks how Strawberries are to be dug without disturbing the roots. Near the collars of the plants the soil should not be moved deeper than would be done by hoeing; further away, in the more central space between the rows, where the roots are fewer and deeper, and where the ground has been more solidified by treading upon it, forking a few inches deep will do little harm. What Mr. Myatt does on his land, rendered comparatively porous and open by the large quantities of manure which market gardeners use, is a very different thing from that which is necessary to be done on newly broken-up clayey soils, which are so adhesive, that through trampling upon them at gathering time, weeding and clearing away runners during the summer, they become impervious to rains, almost as a mass of concrete, especially where the land slopes; it is on such ground as this alone—as "R. S. C." might have seen had he read what I said on the subject attentively—that I advocate a little surface-stirring. On such soils as these, where the precaution has not been taken of breaking up the surface in the way I have described, so as to allow the rains to penetrate them, I have seen in a dry season half the plants die right off a fortnight after the crop was gathered. Strawberry culture with me has been a hobby: I have grown Strawberries successfully on all sorts of land, from light sandy loam and soils of a peaty nature, to the heaviest clay, and I have found it necessary in this, as in other matters pertaining to gardening, to adapt my practice according to circumstances, without which good results need scarcely be expected.—T. BAINES.

Fruit Prospects.—As far as blossom-buds are concerned everything is as yet most promising. Nuts and Filberts are literally laden with male and female blossoms. The buds of Apricots are just showing colour, and Peaches and Nectarines are swelling fast. Apples, Pears, and Plums are not much more forward than usual; for, although we have had such a mild, wet winter the absence of sunshine has somewhat checked vegetation. The protection of choice fruits will soon require attention, and whatever covering is adopted, it should be got in readiness without delay, as bright days, when they do come, will probably be followed by frosty nights.—J. GROOM, *Henham*.

Preservation of Fruit.—De Luca states in the "Répertoire de la Pharmacie," 1876, as the result of repeated experiments, that fruit will keep for a longer or shorter time in close vessels, whether the air-space within the vessels is filled with carbonic acid, or hydrogen, or ordinary atmospheric air, or is a vacuum; that fruit so placed undergoes a sort of slow process of decomposition by disengaging carbonic acid and sometimes hydrogen, and forming alcohol and acetic acid without the interposition of a ferment; that in air-tight vessels the process of decomposition is less complete, owing to the increased air-pressure set up within the vessels by the disengaged gases; that flowers and leaves act like fruit under the same conditions; that fruit, flowers, or leaves in closed vessels may be kept in a state of imperfect preservation for some time, either in carbonic acid, hydrogen, or atmospheric air, by increasing the air-pressure sufficiently; but although these outward appearances may remain unaltered the taste and smell will be impaired.

VILLA-GARDEN ARCHITECTURE.

LANDSCAPE GARDENERS have long known how to adorn our gardens with turf and tree beauty; but too often the house itself, in the hands of speculative builders, is far from being beautiful, and on that account has to be hidden as much as possible by vegetation, instead of being itself an object of interest, contributing its due share of effect to the landscape in which it is placed; Bacon, indeed, tells us that men came to "build stately" sooner than to "garden finely;" but the oft-quoted saying is no longer strictly true. The annexed illustration, from a sketch made on the platform of the Wandsworth railway station, shows how the builder's art (albeit borrowed from more sunny climes) may be made agreeable to the eye and by no means an undesirable object in a garden landscape. The garden itself is shut in by a varied fringe of trees, and at the time when the drawing was made—one sunny morning during the past summer—the principal tower, in its setting of purple, gold, and olive-green leafage, and associated with tapering Poplars, formed a feature unhappily too rarely met with in the neighbourhood of our large towns. At the present time one side of the Common at Wandsworth near the railway station is fringed by a belt of forest trees; but among these the builder is at work, and next summer they will doubtless be exchanged for a row of red brick houses. The same course was pursued at the Crystal Palace, to the utter ruin of one of the finest garden sites in the world. We have at command the vegetation of all temperate climes wherewith to enrich our gardens with both form and colour, but much of this beauty of vegetation is lost through being too often associated with ignoble modern buildings. Amongst living ornaments with which our gardens abound, trees gain most by being associated with appropriate surroundings. A Weeping Willow, for example, on a dry suburban lawn, is necessarily inferior as regards effect to a similar tree planted by a brookside, and while a sombre Yew is rightly placed near a church porch or old abbey wall, how different are the impressions which it produces when contrasted with the bare walls and iron railings of a modern villa! The trees in the annexed sketch consist only of the most common types, but they are amply sufficient, when associated with good architecture, to produce an agreeable effect in a landscape, otherwise of the most common-place character.

F. W. B.

Camellias Out-of-doors at Llanover.—We have Camellias here which have been the admiration of all who have seen them. One measures 15 ft. in width and 10 ft. in height. This year it has been later in coming into bloom than usual. The first bloom was cut from it on January 4, and we have been cutting two or three times weekly ever since, and there are still some 400 or 500 flower-buds on the plant. The old double white kind, planted against the east end of a Pine pit, does remarkably well, and it is coming finely into bloom. Last year we cut from it eight dozen flower-buds; another Camellia, a scarlet kind, grows on a wire trellis exposed to all weathers, and, notwithstanding the hardships to which it is subjected, it becomes covered with beautiful bloom every April. In my opinion Camellias are perfectly hardy if properly planted and well attended to during the summer months.—EDWARD M. DAVIS, *Llanover, Abergavenny.*

THE EDELWEISS AT DANGSTEIN.

HAVING read "H. A. D.'s" remarks (see p. 42) in reference to this plant, I have thought that some account of ours at Dangstein might prove interesting. Towards the end of 1874, Lady Dorothy Nevill had a bouquet of Edelweiss flowers given her by a friend, and wishing to preserve it in a fresh state as long as possible, she had it placed in water. The thought having struck her one day that some of the flowers might contain seed, she examined them, and found her surmise to be correct. After making this discovery, she carefully changed the water herself and daily collected the seed, some of which was sown immediately, while the remainder was kept until spring. It was sown—in both instances—in shallow pans in a compost of sandy peat, leaf-mould, and brickdust, and the pans were placed in a cool orchard-house, where the seeds germinated by scores, those sown in spring turning out the best. The seedlings remained in the pans until autumn, when they were transplanted three or four together into small thumb-pots, in which they were kept until the following spring, when they were again shifted into larger-sized pots. In autumn they were planted out in the Alpine ground—which is warm and sheltered—in a prepared bed of sandy peat, leaf-mould, the siftings from the potting-sheds, and a little rotten manure. Here they stood all the winter without any protection, except during the occurrence of the most severe frosts, when they were lightly covered with bast mats. Many predicted that our attempt to cultivate the Edelweiss in England would turn out a failure; some being of opinion that without its natural protection of snow it would perish in winter with its alternate frosts and rain. Others again thought that the summer would be too hot for it; but notwithstanding these forebodings, our success was complete. The plants grew most vigorously and flowered abundantly, some of the stems being from

9 in. to 12 in. in height and carrying fine branching heads of bloom 5 in. or 6 in. across. They stood the burning heat of last summer without any protection, excepting during a few of the hottest days, when they were shaded with thin canvas thrown loosely over a temporary wooden framework. The flowers that were not gathered were allowed to produce seed, which was collected and has just been sown in the manner already described. We are, therefore, in hopes that our plants of the Edelweiss will be as fine next summer as they were last. We were afraid that the heavy rains this winter might have destroyed the old plants, but on examination we found them still alive, and within these few days they have commenced to grow a little. It is needless to say that last summer they were the admiration of all who saw them, and it was a source of much pleasure to Lady Dorothy Nevill—who was in London at the time—to receive among other flowers a weekly bouquet from her Edelweiss bed at Dangstein. L. T. VAIR.

Cedars of Lebanon and Architecture.—I am glad to benefit by the writings in *THE GARDEN* of so good a forester as Mr. George Berry, but I desire to protest against the idea that the tree or any other tree may be planted in association with one kind of architecture and not with another. Such laws are merely, I think, baseless fancies, which through long repetition pass current without examination.—V.

A Villa near Wandsworth Common.

THE INDOOR GARDEN.

POT-CULTURE OF THE CAMELLIA.

Few plants have increased so much in value during late years as specimen Camellias. Good plants—that is, bushes of tolerable size—are procurable only at high prices, and specimens of the old double white are at a premium, £10, £20, and £30 being common prices for them. One reason, and the principal one, of their increased value is the ever-increasing demand for cut flowers, not in London only, but in every town throughout the provinces. A collection of good Camellia plants is a first-class investment at the present time, either to the nurseryman or private grower. They are not dead stock, like many other plants which realize a profit only when they come to be sold, but yield a handsome return annually, and increase in value at the same time and at a rapid rate, a good, healthy, and fast-growing plant sometimes more than doubling its value in a couple of years. It does not require a very old or large plant, if the branches be annually tied out, so as to form a well-furnished bush down to the pot, to produce 1000 flowers annually, and if sold between November and February, they will fetch a sum about equal to the value of the plant. In several manufacturing towns with which we are acquainted, from 4d. to 8d. were the lowest wholesale prices we ever received for flowers of the Old Double White and Lady Hume's Blush, and we could have sold quantities at those prices, and Reds for a little less. For the above reasons the Camellia is now cultivated in pots perhaps more than ever it was before, though it is a more difficult subject to manage when so grown than when planted out. Success is, however, only a question of care and a little intelligence in potting, watering, shading, and temperature, and to these we shall now refer, and as shortly as possible.

Soil and Potting.

Many and elaborate have been the recipes on the subject of soils and composts, which has given rise to the idea that the Camellia is very particular in that respect; but this is not so, and the fact that it grows luxuriantly in ordinary good tolerably light garden soil, wherever the climate suits it out-of-doors, proves this conclusively. We have seen plants which left nothing to be desired in the way of health growing in a common loam in the foreground of a shrubbery, where they had been for many years; and such instances are quite common. When cultivated under glass, of course, and with an object, it is desirable to give the Camellia as good compost as possible, and this may consist of two-thirds of rotten, light, turfy loam, one-third of peat and leaf-mould together, and a liberal addition of river or silver sand, if the loam and peat be not themselves of a sandy description. Some use peat alone, but the plants do not thrive long in it; and there is not the least reason for supposing that it is ever found in peat in its native habitat, where it grows under the shade of trees, like the undergrowth of our own woods. The best time to pot the Camellias is just when the plants have done flowering, or when they have completed their growth, but before the flower-buds have matured, otherwise they will probably drop unexpanded. We have potted small and large plants frequently just when the young shoots had made their length, and when the buds were in the rudimentary stage, and never had any mishap with them. The pots should be very carefully drained with clean potsherds, putting the largest pieces at the bottom and the smaller ones on the top. Large pots or tubs should have 3 in. or 4 in. of drainage, and the smallest-sized pots should not have less than 1 in. The Camellia in a healthy state is a vigorous rooter, and may have a good shift when it is repotted; for it is not desirable to shift the plants often, especially after they get large, good top-dressings being sufficient afterwards. Small plants may have 1 in. more room, and large ones may be allowed from 3 in. to 6 in. all round, accordingly as they are weak or vigorous; and it is sometimes better, in the case of unhealthy plants with few roots, to reduce the ball of soil, and put them into less pots than before; but growing plants must have more or less additional room. Before potting it must be ascertained whether the ball of soil is dry or not in the winter—a thing likely to occur; and, if so,

it should be steeped in water until there is no doubt about it being soaked through. In potting, the soil should be pressed moderately firm round the roots; but beating it hard with rammers is unnecessary. Plenty of room should be left for water, 3 in. or 4 in. in large pots, and proportionately less in small ones, but enough always to hold a sufficient quantity to soak the roots at one watering. After all the plants are potted they should be set, whether by themselves or among other plants, so closely together that the pots will be completely shaded and cool; or, what is better, they should be plunged in ashes or soil. If neither of these arrangements can be carried out, then some means should be taken to shade the pots, and prevent alternations of heat and cold and drought, which the Camellia is not able to endure.

Watering and Shading.

The dropping of the buds of the Camellia is frequently due to neglect or excess in watering, and general ill-health may often be traced to the same cause. The soil in the pots should never be allowed to become dry, in the real sense of the word, and neither should it get sodden or sour. It is difficult to convey to the unpractised hand what is meant by a "healthy" or "sweet" soil; but we should like to do so, and we can liken such a soil to nothing better than newly turned-up soil out-of-doors after it has been well drenched with a thunder shower, supposing the ground to have been parched previously. The danger most to be feared, however, is dryness at the root unless much spongy peat has been used, and then there may be danger from over-watering, but, as a rule, ample watering should be supplied, if the drainage be safe and sufficient, for in an ordinary soil all superfluous moisture soon drains off. Out-of-doors in this country the Camellia does not appear to suffer seriously from continued bright sunshine, but under a clear glass roof it does suffer without doubt, both in the old and young leaves. Ground glass has been tried in the roofs of Camellia houses, but the shade afforded by such means is scarcely dense enough, as we happen to know from experience, and we would prefer either a cotton shading or a coating of whitewash; but the cotton shading, which should be thin, is the best, as it can be removed in dull days and in the evenings, for it is only bright sunshine that the Camellia dislikes: it enjoys abundance of subdued light. The plants should therefore be shaded from the direct rays of the sun as soon as they gather strength in the morning, and the shading should not be removed till late in the afternoon.

Temperature.

When the plants are wanted to flower from November onwards through the winter, they should be started about March in a genial temperature of 55° min. to 60° or 65° max., with regular ventilation, avoiding draughts; and these temperatures may be continued till summer advances, and then they can be kept up without fire-heat. So treated the plants will grow and mature their buds by October, and they will open without forcing, which the Camellia does not like; or the plants may be pushed on in a Vinery, which is started about April, and with the higher temperature of this they will be brought forward earlier than otherwise. At one time we grew a number of large plants in a late Vinery, where they remained all the year round. The summer temperature of the Vinery, which ranged from 65° to 80°, seemed to suit them, and they always used to begin flowering in October of their own accord, and continued to do so most of the winter, the house being kept at a temperature of 45° or 50°, and dry for the sake of the Grapes. In other respects the Camellia will do well in a cool greenhouse or conservatory, but here it does not begin to flower till February or March.—"Field."

Cyclamens and Sun-heat.—In Mr. Cornhill's article on Cyclamens (see p. 83), the following sentence occurs:—"The exposure of the Cyclamen in any period of its existence to strong solar heat and an arid atmosphere appears to me to be subjecting it to a treatment quite foreign to its nature." Now, not far from Athens I have seen a large tract of wild ground covered with flowering Cyclamens in the latter part of October; the air was filled with the fragrance of this exquisite flower, and the bright, yet delicate, colouring is strong in my recollection after the lapse of some fifteen years. In Greece the sun is hot, and the air arid.—CHRISTINE.

THE KITCHEN GARDEN.

NOTES ON THE BEST NEW VEGETABLES.

SINCE December 14, when the first seed catalogue for 1877 arrived, I have received no fewer than sixteen, every one of which is excellent in its way, but to the inexperienced, who wish to make a limited selection of the best seeds only, considering the numerous novelties described, large catalogues must be perplexing in the extreme. To such a few notes concerning the best kinds of vegetables may perhaps serve as a guide, as they are written from practical experience of all here named, except the Radish and Dwarf White Celery.

POTATOES.—Fenn's Early Market, at once the earliest, handsomest, and finest-flavoured round Potato yet in commerce, is sure to become a favourite with Potato-growers. There is in certain quarters a tendency to underrate Mr. Fenn's seedling

Early White Stuttgart Giant Radish.

Potatoes, on the ground of want of size and productive properties, and with some few of his first seedlings perhaps justly; but of late Mr. Fenn has made wonderful advance in the way of size, and though Early Market is not a large Potato, its productive qualities are immense, and it has the additional recommendation of having a haulm rarely exceeding 1 ft. in height. Early White Kidney is another of Mr. Fenn's seedlings, and an excellent companion to the foregoing; it is much earlier than Lapstone, and possesses all the good qualities of that deservedly popular variety. Amongst recent American introductions of the Potato none can compete with Snowflake. It is both handsome, prolific, and of good quality, being more akin to the English kinds in flavour than any previously introduced—for without exception all the American kinds are wanting in this one essential element, viz., flavour.

RADISHES.—The Early White Stuttgart Giant Radish is highly recommended by Messrs. Vilmorin, of Paris. It is remarkable for size and rapidity of growth—even in a few weeks it attains the size of the Round Winter Purple Radish; it is somewhat later than the Summer Yellow kind, but the root is much larger.

PEAS.—There are many claimants for "the finest in cultivation" position, and in Dr. McLean (Turner) we have decidedly one of the finest; it is of sturdy growth, attaining a height of from 3½ ft. to 4 ft., and the pods of Peas literally cover the haulm: it is of excellent flavour, but in this latter respect Sutton's Duchess of Edinburgh bears the palm, for it is certainly of as fine a flavour as can well be conceived; it seems closely allied to British Queen, and, like that variety, continues

in bearing a long time. Of first early kinds, Laxton's The Shah and Laxton's William the First, being wrinkled Marrows of the finest quality and within a few days as early as Ringleader or Daniel O'Rourke, must eventually oust those varieties, and not on the ground of earliness and quality alone, but also by reason of their greater productiveness. As a good standard midseason and late kind, none yet equals in all points Veitch's Perfection.

FRENCH BEANS.—Canadian Wonder is a decided acquisition to the extensive list of this desirable vegetable, having pods of large size, with no falling off as to numbers on a stalk; it is a grand variety to sow for a main crop.

BROCCOLI.—Among these there are two or three kinds of recent introduction that are worth noting: the first is Veitch's Self Protecting Autumn. I grew a quantity of it last season, and began to cut the first week in December, and have only just finished; it will take the place of the favourite, Snow's Broccoli, as it turns in earlier, and is not so quickly over. As a late Broccoli Sutton's Late Queen deserves a prominent position; this kind and Lander's Goshen Late Protecting are indispensable if Broccoli be in request till the early Cauliflower is ready at the end of April and the beginning of May. Another kind which is not so generally grown as its excellence would warrant, is Sutton's White Sprouting, which produces abundance of small rosette-like heads all through February and the early part of March; it is hardier than the ordinary kinds of Broccoli, and serves well as a substitute for that in the event of scarcity.

CELERY, too, has obtained a place on the novelty list, and the best I have tried is Major Clarke's Solid Red, a sturdy-growing

New Dwarf White Celery.

kind and of fine flavour. Messrs. Vilmorin likewise speak well of a Dwarf White Celery, of which the annexed is a representation, but I have not as yet tried it. This Celery differs materially from the kinds usually cultivated; the size of its stalks makes it resemble the Early Dwarf White, but it is more erect, a quicker grower, and the stalks are wider and closer, which makes them blanch more readily with but little artificial aid. One of the great advantages of this variety is that it does not form any suckers, and thus all the strength of the plant is thrown into the heart. On account of the latter peculiarity, and its very early and erect growth, this Dwarf White Celery can be planted much closer than other kinds.

ONIONS.—The New Queen Onion is also worthy of notice, especially by those who experience a difficulty in securing picklers on account of the bulbs getting too large, as being

but small when fully grown, no difficulty is experienced on that score; another recommendation is its quick growth, for if sown in the month of February it may be harvested early in June.

I have thus summed up in as few words as possible my impressions of a few of the novelties contained in the vegetable seed lists that are really acquisitions to an already ample variety, but the cry is "Still they come;" and every year the so-called novelties get more numerous and the catalogues grander and larger. Would it not be discretionary on the part of seedsmen to make a halt? W. W. H.

POTATOES FOR EXHIBITION.

WHILST every successive season shows small but valuable additions to the list of exhibition Potatoes, it is certain that some old kinds hold their own against the new comers, both in the matter of shape and excellence for the table. Certain people who condemn Potato shows, maintain that the beautifully-formed tubers seen at the Alexandra Palace and elsewhere are inferior for eating purposes to coarser-looking kinds. This is, however, a mistake, based upon a very imperfect knowledge of the qualities of what are popularly known as "Show" varieties. Take the singularly smooth, handsome Lapstone, for example, one of the most popular kinds for the table, of superb quality, and yet inevitably found in the front rank of White Kidneys on the exhibition table. There are also the beautiful-coloured Kidneys, Bountiful and Late Rose; coloured Rounds, Scotch Blue and Blanchard; and white Rounds, Onwards and Schoolmaster, all well known for their specially good qualities when cooked, and fair examples of the quality of Show Potatoes; and yet when these are seen in all their beauty on the exhibition table, excelling larger and coarser, deep-eyed kinds, some people will exclaim, "Ah, they are very beautiful to look at, but not fit to eat!" But apart from all considerations of table quality, there are many persons who are cultivators of the Potato for precisely the same reasons that other persons grow flowers, not for their own consumption or for profit, but because they love to cultivate them, to watch their growth, to note their respective produce, and to exhibit with pride the beautiful tubers they have raised. It is rather to this class of connoisseur cultivators that I invite attention to exhibition tubers, because there are many who are only too pleased to obtain useful information respecting new kinds of Potatoes that may be worth a trial during the ensuing season. Of White Kidneys the finest of new kinds are International Kidney, Covent Garden Perfection, Success (a large American kind of the Snowflake type), and Edgecote Seedling (a very fine strain of the old Lapstone). White Rounds—Porter's Excelsior, although generally assumed to be but the old Handsworth, is still the handsomest of White Rounds, but it is closely pressed, and probably may soon be beaten by White Emperor and Schoolmaster, the first not yet in commerce, and the latter only sent out as late as last year; in reality, no new White Round exhibition kinds are being offered this season. Coloured Kidneys find two valuable additions in Superior, a new Red American kind, and Garibaldi, a very fine Red Kidney, resembling a large Bountiful; Keystone is another recent introduction from America, a large flat pale rose-coloured Kidney, and is well worthy attention; Ruby, a very pretty early Red American Kidney, will probably be seen more largely on the exhibition table this season, last year having been too dry to bring it to its full size. Some Scotch growers exhibited at the Alexandra Palace last September a handsome Purple-red Kidney under the name of Crimson-Walnut-leaf; this is not known in the south either by name or appearance, but appears to be a distinct and acceptable variety. Then of Coloured Rounds, perhaps the handsomest acquisition is Lye's Favourite, a singularly handsome kind, having a white skin with rich rosy-red blotches of colour about the eyes; Lady Webster, somewhat similarly marked, but of paler tints and flattish in shape; and Grampian, a very fine Red Round, evidently intermediate between Red Emperor and Red Regent, are the most striking of new Coloured Rounds. Allow me to add a selection of twenty-four varieties in their respective sections, the best which I know for exhibition:—

WHITE KIDNEYS—Snowflake, International, Lapstone, Waterloo Kidney, King of Potatoes, Covent Garden Perfection.

COLOURED KIDNEYS—Purple Ashleaf, Garibaldi, Late Rose, Salmon Kidney, Ruby, Bountiful.

WHITE ROUNDS—Porter's Excelsior, Schoolmaster, Rector of Woodstock, Model, Onwards, Bresee's Prolific.

COLOURED ROUNDS—Lye's Favourite, Red Emperor, Scotch Blue, Early Oneida, Blanchard, Vermont Beauty. A. D.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Orchids.—Amateurs are frequently deterred from attempting the cultivation of Orchids through the prevalent opinion that they are difficult to grow, and that they require houses especially for themselves, besides being very expensive. No doubt all these objections hold good so far as relates to many species, but there are numbers quite equal to the best varieties in the beautiful character of their flowers and the freedom and profusion in which they are produced that succeed just as well in an ordinary cool stove associated with other plants as they will if grown in separate structures. They also have the merit of being cheap, being little or no higher in price than many hard or soft-wooded stove subjects. The undermentioned are a few that any amateur who has an intermediate-house or cool stove, and who has had some experience with the plants usually grown therein, need not fear failure in the production of good specimens. The first I may mention is *Cattleya Mossie*, with its numerous forms, the principal difference in which consists in the degrees of brilliancy and purity of their colours, but the most inferior forms would be considered magnificent in the absence of the finer varieties; it blooms for several weeks in the spring. *C. amethystina* is another fine species, producing large spikes of numerous amethyst-coloured flowers with darker spots, also a spring-flowerer; *C. Loddigesii*, another very free-blooming kind with violet-coloured flowers, produced freely in summer and autumn. With these may be classed *Lælia purpurata*, one of the grandest Orchids ever introduced; intense purple, with a little orange on the purest white; it is also a spring and summer flowerer. The above plants require much the same treatment: pots one-third filled with clean crocks for drainage; soil, good fibrous peat with a fourth of small crocks mixed therewith. Their growth is made in the summer and autumn, during which time give them a night temperature of 60° or 65°, with 10° or 15° higher in the day according to the weather, slightly shading them from the sun, and keeping the soil somewhat moist but not too wet. In the winter, after they have completed their growth, a night temperature of 50° is ample; at this time the roots must be kept almost quite dry until the flowers begin to push up in the spring. The two most useful and easily-grown *Dendrobiums* are *D. moniliforme* and *D. nobile*, the former flowering early in the winter, and lasting six weeks in beauty, the other succeeding it in the spring and summer, the flowers equally lasting. They commence to make their growth after blooming, when the soil must be kept quite moist, and a little shade be given, with the temperature similar to that of the *Cattleyas*. After their growth is completed in the autumn, they should be kept perfectly dry at the root, till the flowers push in the spring, when a very little water must be given; they will bear in the winter as low a temperature as 45°. The pots must be well drained, and the soil as recommended for the *Cattleyas*. *Cypripedium insigne* is the commonest but most useful of the family, especially for cutting, in which state its flowers will remain fresh for three weeks or a month; it requires 2 in. of drainage in the bottom of the pots, and good yellow loam with a little sand makes the best compost for it. It never should be re-potted or the roots disturbed at all until it absolutely needs more room; it flowers in the autumn, and requires plenty of water during the spring and summer, but very little in the winter. *Zygopetalum Mackayi* and *Z. cinnabarinum* also thrive best in loam; they are free-blooming plants with finely-marked, exquisitely-scented, large flowers; the principal colour is white streaked and spotted with dark bluish-lilac; they should be kept moderately moist in the spring and summer whilst making their growth, and somewhat drier in the winter. These latter plants will succeed during the winter and summer with a similar temperature to the former. For bouquets and vases, the blooms of all the above-mentioned are amongst the most prized.

Stove and Greenhouse Plants.—If *Bougainvillea glabra*, *Allamandas*, and *Clerodendrons* have not yet been started, that operation should be commenced at once, as half their usefulness depends upon giving them a long season. The soil during the winter having been kept quite dry, the balls will need a thorough soaking before starting; there is no better way of effecting this than placing them for a few hours in a bucket of tepid water. *Allamandas* ought to be attended

to in the matter of potting; they like good loam well enriched with rotten manure, and as much sand added to it as will keep it open, the soil being made quite solid. *Clerodendrons* and *Bougainvillea glabra* must not have their roots disturbed much, or the flowering will be greatly interfered with. *Ixoras* ought to be now potted in good peat mixed with a sixth part of sand. *Fuchsias* struck in the autumn, that have filled their pots with roots, must be moved on into others before they become at all pot-bound; they may have a 4-in. shift; let the soil consist of four parts good loam and one part leaf-mould and rotten manure in equal proportions, with a fair amount of sand, but it must not be made too light, as *Fuchsias* thrive best when the material in which they are grown is pretty strong; make the soil quite firm in the pots, and syringe overhead every afternoon; this will keep down red spider as well as encourage growth; by stopping the shoots they will be kept bushy. *Camellias* that through excessive cutting have got into a straggling, scraggy condition, may be headed down, an operation which they bear better than many subjects, and after which, if well treated, they very soon form handsome heads. It is a good plan, should these plants have got into the state above described, to head some down every year till the whole are by this means refurnished. This operation should not be delayed any later than the middle of February. The place where they have been grafted will generally be visible not many inches above the collar; they ought to be cut down to within 2 ft. above the graft, then put them for seven or eight weeks in a cool house, and, if the soil be not too dry, do not give them any water; after this remove them to a genial, growing temperature, and when the eyes break, all those that are more than 8 in. or 9 in. above the grafted part must be rabbed off: there will be quite sufficient left to make a good head. As soon as the growths are 6 in. long, the stumps must be cut down to the point from which the topmost shoot springs; the reason for not cutting so low as this at first is that stronger growth is pushed when a good length of old stem is left till they have broken. If the roots be not in a good state, this heading down must not be attempted.

Kitchen Garden.—It will be well to go over late Potatoes intended for use during the spring and rub off the sprouts, which, if allowed to stay on till they get long, spoil the tubers. Keep them where it is dark and as cool as possible; also see to Carrots, Beet, &c. Whatever may be the material in which these vegetables are stored, it should not be at all wet, as such a state encourages them to throw out shoots. If some roots of Rhubarb be placed in a shed they will soon push and be ready for use before that left outside. A portion of the crowns out-of-doors may have a few inches of litter put over them, by which means they will be protected from spring frosts, and be more forward by a fortnight than if entirely exposed. Of Onions a good crop can only be obtained by early sowing, and as the ground should always be dug at least several weeks before the seed is put in, if not prepared in the previous autumn, it should be dug as soon as it is sufficiently dry to be trodden upon, liberally manuring it, a considerable portion of which should be got down about 12 in. or 15 in. deep. After the land has been dug a sprinkling of fowl manure should be strewn on the surface and remain exposed to the air until a few days before sowing and then pointed in 6 in. deep, with 1 in. of soot and a little salt. This treatment should produce a heavy crop of large bulbs, which are much milder and generally preferred to small-grown examples, that are hot and stronger-flavoured. Radishes sown outside and protected with litter will not be long before they are up if the weather continue mild. As soon as they are aboveground the litter must not be allowed to remain over them in the daytime; it should be taken off carefully in the mornings and put on again in the evenings till they are strong enough to bear full exposure.

Raspberry Beds ought to be gone over with the hoe and all the weeds removed; they should then have a good mulching with manure. To grow Raspberries well they need more manure than other bush fruits; 3 in. put on the surface each year will not be too much.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

February 12.—Potting off variegated *Pelargoniums* struck in boxes; also *Verbenas*, and putting them into heat; and a batch of *Gloxinias*. Shifting *Hollyhocks* and *Centreas* into larger pots, and placing them in orchard-house. Putting in cuttings of *Iresine Lindeni*, *Impatiens Jerdoniae*, *Salvia patens*, *Fuchsias*, *Coleus*, and *Gesneras*, the latter consisting of leaves. Making hills for *Cucumbers*, in order that they may get warm and ready for planting. Dividing *Dactylis glomerata* var. and *Poa trivialis elegans*. Tying down first

Muscat shoots. Staking early Peas. Strawing up ice-house doors and making safe against sudden change in the weather. Fumigating greenhouse for fly and thrips. Examining *Stephanotis* for scale. Applying a mixture of lime and soot to Pear trees and Red Currants, as birds are attacking their buds. Taking up *Artichokes* and *Par-snips*. Giving first Muscat and first *Hamburgh Vines* a top-dressing of cow manure and well watering it in. Manuring Rose border ready for digging. Making up last Potato bed. Stopping bedding *Calceolarias*. Weeding walks.

Feb. 13.—Re-arranging *Odontoglossum*-house. Putting in cuttings of *Salvia* and *Mesembryanthemum cordifolium*. Getting all bulbs out that have been plunged in ashes, and putting them where they can be just protected from frost. Dusting *Apricots* with soot and lime to prevent sparrows from eating their buds. Thinning *Peaches* in earliest house. Raking up worm-casts on Grass. Plants ready for house decoration—*Hyacinths*, *Narcissus*, *Lily of the Valley*, *Primulas*, *Heliotropes*, Scented-leaved *Pelargoniums*, *Deutzias*, *Tulips*, *Imantophyllums*, *Lilacs*, *Sweet Briers*, *Dielytras*, *Azaleas*, *Gardenia* blossom, *Crocuses*, *Snowdrops*, and *Callas*.

Feb. 14.—Preparing a bed under south wall for *Radishes*. Potting off *Chrysanthemum Sensation*, *Veronica variegata*, and *Gazania*. Putting in *Verbena* cuttings. Planting *Seakale* for next season's forcing. Regulating *Creepers* in conservatory. Top-dressing *Lapagerias* with good peat and sand. Starting third *Peach*-house at 55° at night.

Feb. 15.—Digging among *Currant* trees. Sowing *Melons*. Potting *Zonal Pelargoniums* into their flowering pots. Potting *Lilacs*. Shifting some potted-off *Petunnias* into 48-sized pots for early flowering. Putting in cuttings of scented *Verbena*. Planting *Artichokes*. Emptying and re-filling another pit with heating materials for cuttings. *Cucumber* plants sown in October coming into bearing. Raising first *Muscat*-house to 70° at night.

Feb. 16.—Potting *Gladioli* in 60-sized pots, and placing them under greenhouse stage to start. Potting *Lycastes* in peat and Moss. Planting spare cases with *Cauliflower*. Putting in more *Keen's Seedling Strawberries* to force. Shifting young tree *Mignonette*. Tying up climbers on verandah. Pricking manure into *Asparagus*-beds. Earthing up second pit of *Potatoes*. Raising *East Indian Orchid*-house from 65° to 70° at night, from 70° to 75° by day fire-heat; and raising *Dendrobium*-house to 60° at night and 65° by day fire-heat, both being allowed to rise higher with sunshine.

Feb. 17.—Potting off young *Fuchsias*, *Lobelias*, *Chrysanthemums*, and *Tuberoses*, putting the latter in heat. Pricking out earliest *Celery* in a one-light frame; also *Tomatoes*, seven to a pot. Putting in *Mrs. Pollock Pelargonium* cuttings; also *Pink* cuttings in manure-bed, and some *Plumbago*. Shutting up *Maréchal Niel Rose*-house to induce the plants to bloom. Putting *Daturas* into *Peach*-house. Going over *Muscats* in flower daily with a camel's hair brush. Syringing *Cherry* trees with soap-suds to kill any fly which may be lurking in crevices. Thinning a great many fruits off early *Peach* trees. Finishing the pruning of *Gooseberry* trees. Keeping *Phalenopsis* at 70° at night, *Dendrobiums* and *Cattleyas* at 60°, and *Odontoglossums* at 55°, allowing a fall of some 3° or 4° towards morning. Raising second *Vineries* to 60° at night, buds mostly burst and showing fruit.

Orchids.

Some apply warm water to *Orchids*, and recommend that hot-water pipes should be laid through the tanks in *Orchid*-houses. My own experience, gained both by observation and experiment, has convinced me that such a course is wholly unnecessary. Although water heated slightly by artificial means may not be perceptibly injurious to plants upon which it is used, cold rain-water stored in nubeated tanks of good size in the *Orchid*-house, will be found to be more beneficial to the flowers, and its temperature will not differ greatly from that of the house all the year round, whereas the temperature of the water in tanks having hot-water pipes passing through them will be in accordance with the heat of those pipes, and consequently the water may sometimes have to be used cold; and at other times, when the heating apparatus has to be kept going briskly, or when there is but little water in the tanks, its temperature will be increased to a high degree, higher often than even an advocate for the use of warm water for *Orchids* could wish; nevertheless, there being no other at hand, it is used, and the plants suffer accordingly. The worst feature as regards the system of running hot-water pipes through tanks in which water is stored is that the temperature of the water is highest throughout the coldest and driest part of the year, when the greater portion of the plants are at rest; the result, therefore, is that warm water is applied during the resting season and cold at the height of the growing season, while in carrying out the warm-

water system correctly, the very reverse of this would be necessary. The plants most liable to be injured by the treatment referred to are the occupants of the cold *Odontoglossum* and intermediate houses; those of the East India-house seem better able to resist its evil effects; and hence it is that we often see healthy subjects in a house, the tank of which has a hot-water pipe running round it. This is often done, too, with the view of increasing the humidity of the atmosphere, and in this respect it may at times be slightly beneficial; but at the present time, when the East India-house should be drier than usual, it would be injurious. There remains, therefore, only one course to pursue in a house so arranged, and that is, to shut off the heat from the pipe running through the tank in order to prevent the moisture rising from the water. The inconvenience of this will be seen at a glance; those plants which have hitherto received warm water will have to be supplied with cold for a time, or the water being kept warm as usual the atmosphere of the house will be too moist, and many of the plants will not be prepared for flowering. It is better, therefore, to class the East India-house with the other houses, and to have the tanks in it unheated and to trust for humidity to other means. I am convinced that cold rain-water stored in tanks in houses (not taken from outside) is the best for all plants, and I have seen disastrous results accrue to plants from the application of water at a high temperature.—JAMES O'BRIEN.

PLATE LX.

THE CRIMSON SATIN-FLOWER.

(*BRODLEA COCCINEA*).

UNLESS our friend Dr. Bolander can boast of a more phlegmatic temperament than is usually associated with an enthusiastic love of botanical pursuits, it can hardly be doubted that his first glimpse of the *Brodiaea coccinea* gave rise to sensations of a most agreeable character; for among the dwarfier plants of the prodigally endowed region of which it is a native it would be hard to find another offering in its flowers so striking and so unrequited a combination of colour, to discover which one must travel far southward to the Peruvian Andes, where, among the *Amaryllids* peculiar to that range, the same deep crimson colour, effectively contrasted with vivid green, occasionally obtains. The *Brodiaea coccinea* is not only uncommonly showy—a feature which it shares with some other beautiful *Liliaceæ* from the same State—but, unlike some of them—for instance, the *Calochorti*—it is a most manageable bulb, and has shown a disposition to adapt itself to the vicissitudes of our fickle climate, so that the amateur who may be tempted to invest a few shillings in its acquisition need not fear to see his bulb becoming year by year small by degrees and beautifully less, until finally it becomes conspicuous by its absence, and vanishes to the limbo, surely now well tenanted, of lost bulbs. It appears to succeed in soil of almost any description between the extremes of very light and very heavy, but makes the most vigorous growth in substantial but friable, silicious loam; and the accommodating character of this handsome plant is further shown by the fact that the bulbs may be kept out of the soil for at least six months, that is from August to February, without injury. It is not, however, desirable to delay planting beyond October, as the flowers of the late-planted bulbs are scarcely so fine as they otherwise would be; and once planted they may remain undisturbed for several years, unless raised for the purpose of division. Offsets are produced in some quantity, and the plant may also be increased by seed, which vegetates pretty freely after an interval of some weeks, the resulting bulbs attaining a flowering size in from three to four years. As the plant is of slender habit, the flowers being usually produced on a naked scape $1\frac{1}{2}$ ft. high or more, not less than three bulbs should be grouped together, and five or six will produce a still better effect; a single Osier rod placed in their midst will suffice to support the somewhat fragile stems. In some soils, notably those of a light, sandy character, the foliage is sometimes liable to disappear, or at least wither partially, by the time the flowers are in perfection. This may probably be remedied by sowing a few seeds of some neat annual of dwarf habit, which would carpet the soil around the stem, and bloom subsequently to its removal, or in the case of the early-flowering annuals, such as *Limnanthes*

and *Leptosiphon*, simultaneously with the bulb. The general aspect of the plant is well shown in the accompanying figure, though it is, perhaps, matter for regret that the specimens from which the drawing was made were somewhat too far advanced, as indicated by the pale and straightened tips of several of the flowers. From an early stage, and up to the period of expansion, the limb of the flower is of an agreeable green tint, which it loses as the flower fades, until it assumes the appearance shown in the uppermost blooms on the plate. Botanically the genus *Brodiaea* is characterized by having a funnel-shaped or tubular perianth, with a six-lobed limb varying in length, three linear anthers, more or less sessile in the throat of the tube, alternating with which are three flattened, yellowish-white bodies, or abortive stamens, termed staminodes, which may be observed, in the illustration of *B. coccinea*, to project beyond the tube. The ovary is sessile or shortly stalked, having from four to six ovules in each cell, with a straight, slender style and capitate stigma. It matures into a membranous, oblong, three-angled capsule, opening by three valves, each cell containing from two to four small black three-angled seeds. In all, the flowers are produced in an umbel from a many-leaved spathe, or erect or nodding pedicels, which are articulated at the summit. It includes but five species, viz., *B. grandiflora*, with flowers of a deep violet blue, on which the genus was founded by Sir James Smith, and of which there are several forms, differing chiefly in stature and the size of the flowers, all being very desirable and pretty hardy bulbs; *B. congesta*, with smaller flowers, in a crowded head, of a reddish-violet colour, less ornamental than the preceding; *B. multiflora*, a species differing from the last chiefly in the blue colour of its flowers, and in the staminodes being lanceolate and entire instead of quadrate and bifid; *B. volubilis*, a remarkable plant, with a long, twining scape, and a crowded umbel of rather small rosy-purple flowers; and, lastly, the *B. coccinea*, the subject of the foregoing remarks. All of them are natives of Western America, occurring chiefly in California, Oregon, and British Columbia, and have been long known to botanists. *B. coccinea*, even though first introduced to cultivation by Dr. Bolander, was, it seems, first discovered by Mr. W. Lobb, but does not appear to have been sent home in a living state. W. THOMPSON.

Ipswich.

Finely-flowered *Eucharis amazonica*.—About two-and-a-half years ago I furnished some account of three of the best plants of this which I had then seen. The best plant, according to my note-book, had forty-one spikes upon it, and within nine months the same plant had about seventy spikes; on each of these spikes I counted five flowers, making in all 350. The size of the pot in which they were growing was about 16 in. Just now there is a plant here with twenty-four spikes, and a smaller plant just going out of flower on which there were nine spikes. Such plants as this latter, not extra large, but neat and proportionate, are quite as useful, and in some respects more so, than larger plants.—ROBERT MACKELLAR, *Abney Hall, Cheadle.*

Roman Hyacinths the Second Year.—Everybody is well aware that Dutch Hyacinths are not worth the trouble of planting a second year after they have once flowered; but what about white Roman Hyacinths, are they worth retaining? and if so, how should they be treated from this time until next autumn?—*North Devon.* [I must confess that hitherto Roman Hyacinths have not succeeded with me a second year, but this season I am planting them out in very dry, sandy ground immediately they have flowered, and I am in hopes of being more successful. I have planted them before, but if the land be at all wet they all rot and disappear. I imagine it will be necessary to take them up and store them in May or June, and replant them in September. For several years both Dutch *Narcissi* and Hyacinths did not succeed a second year with me, but since I have tried planting them in very dry, sandy soil, the Dutch *Narcissi*, such as *Queen of the Netherlands*, &c., flower every year, and the bulbs increase both in size and number, and altogether do just as well as imported ones. I do not take *Narcissi* up, but allow them to remain in the ground all the year. Dutch Hyacinths I always plant out and lift again in June, and replant in October, and always with great success; the same treatment holds good with regard to Tulips of the early Dutch sort, as well as with several other kinds of bulbous plants.—W. DENNING.]

THE CRIMSON SATIN FLOWER (BRODIAEA COCCINEA - A GRAY.)

LILY BULBS.—I.

It would be difficult to name any family of hardy flowers which has attained so much popularity in our gardens and garden literature in so short a time as that of the Lilies, and one of the reasons for this, apart from the stately beauty and variety of these plants, is doubtless the increased interest now being taken in the more beautiful plants of all temperate climates, although not a little of the attention which Lilies now receive is due to Mr. Baker, who, by his "Review," directed many European collectors to their natural habitats. To Herr Max Leichtlin, of Baden Baden, is due the credit of introducing many species to our gardens, and here Mr. G. F. Wilson, Mr. J. McIntosh, and other private growers have done much in the same direction; while the activity displayed by Mr. Bull, Mr. Barr, the Colchester Bulb Company, and others, has resulted in the more general cultivation of Lilies everywhere. The main bulk of Lily literature, whether pictorial or otherwise, has been devoted to the above-ground growth of the plants to the flower-stem and its burden of green leaves and graceful flowers, and, seeing that this is so, we have decided to devote a little attention to the underground growth or bulb development, but not so much with the idea of directly instructing our readers, as to show that the whole subject of underground plant growth is worthy of their own personal observation, since it is only by obtaining records from many different soils and climates, or systems of culture, that we can hope to add to what is already well known of Lily bulbs by most cultivators. Any such observations or sketches of bulbs (better still, the loan of the bulbs themselves) will be welcome; and as it is self-evident that we must learn to grow plump, perfect bulbs before we can hope to see Lily flowers in all their possible beauty, the importance of looking to what Mr. Barr tells us is "the root of the matter," that is to say, the bulb, will be apparent. All our sketches hereafter to be given were made during November of last year, the bulbs having been selected as type specimens and kindly lent to us by Mr. G. F. Wilson, Mr. Peter Barr, Mr. W. Bull, and the Colchester Bulb Company. After our sketches and notes were taken, the whole were again compared with fresh bulbs in Mr. Barr's collection, so it will be seen precautions have not been spared to insure their approximate correctness, and consequent value to Lily cultivators.

Form, Colour, and Uses of Lily Bulbs.

The form of Lily bulbs, even of the same variety, is liable to vary according to different phases of their growth; thus young bulbs, before flowering, have plump, closely imbricated scales, but when the flower-stem pushes up the scales become thinner and wider apart, owing to part of their substance having been attracted to the flower-stem. Imported bulbs are generally loose and open, especially if they have been kept in a dry atmosphere, just as the scales of Pine cones open under similar conditions. It is, perhaps, impossible to discover why the flat-scaled American Lilies, such as *L. Washingtonianum*, *L. purpureum*, and one or two others, have assumed the sub-rhizomatous or oblique-creeping habit so characteristic of the thick short-scaled bulbs of *L. pardalinum*, *L. canadense*, *L. parvum*, and others. I saw over a thousand of *L. Washingtonianum* bulbs, and considerable quantities of *L. Humboldtii* and *L. Bloomerianum ocellatum* at Mr. Bull's, all showing this oblique sub-rhizomatous habit; and those of *L. Washingtonianum* in particular looked as though they had grown among flat rocks or shale found in some Californian districts, embedded under 8 in. or 10 in. of the soil in upland localities. Whatever the object of this bulb extension may be, however, matters but little, the result of it being that the hungry young roots are enabled to push their way in fresh soil every year. Different conditions of nutriment again, as supplied by more or less suitable soils, affect both the size, shape, and colour of all Lily bulbs, although not so much as to remove the almost indescribable characters by which the practised eye distinguishes them. The colour of Lily bulbs in different soils is very variable, this variation depending in a great measure on the oxidation due to atmospheric exposure, this exposure being regulated by the density of the soil, or its permeability to light and air. That there is some other inherent cause for this colour development, however, is shown, since, in precisely

the same soil, bulbs of *L. Browni* turn purple on exposure, while bulbs of the *L. Martagon* and European Turk's-cap Lilies as invariably become yellow under the same treatment. The whole question of local colour predominating in any part of the plant, as shown in some Lilies, is very interesting, and often is an aid to garden nomenclature, when the colours of the flowers alone fail us. Thus, as Mr. Barr informs us, he was long in arriving at any tangible characters by which to distinguish the different varieties of the extremely variable *L. speciosum*, until he observed the local colour of the flower-stems, leaves, and anthers of the flower which simplify the whole matter. The Dutch growers expose most of their bulbs so as to give them a good colour, but, apart from mere appearance, the practice is not a desirable one; indeed, the purchaser has to pay for the colour in the shape of lessened vigour, due to the evaporation consequent on exposure. Of course this drying and colouring process is essential where bulbs have to be stored for months, so as to be ready for transit or sale, but all cultivators are now tolerably well agreed that the sooner Lily bulbs are re-planted after they are moved from the soil the better. Colour alone cannot be taken as a character in determining Lily bulbs, since in *L. speciosum* we find white, yellow, orange and brown, reddish-purple, and even dull crimson bulbs, all yielding precisely the same coloured flowers; or perchance we find that a white bulb produces dark rosy-crimson spotted flowers, while the white-flowered *L. speciosum album* often has bulbs of a deep purplish-crimson colour. The yellowish-white bulbs of some of the orange Lilies, as in the forms of *L. elegans*, become bright purplish-crimson if fully exposed to the sun and air for a few weeks, and the same is observable in imported bulbs of *L. Wallichianum*, the bulbs of which are yellowish-white when removed from the soil. Perhaps the forms of *L. Martagon* are most constant in colour, their bulbs being of a bright yellow colour, as are those of *L. albanicum*, *L. pyrenaicum*, and other European Turk's-cap Lilies. *L. Browni* frequently has an oblate purple bulb dotted with dark markings; some, however, are yellowish-white, and while *L. Washingtonianum* and *L. Humboldtii* generally (and I have seen them in heaps of several hundreds together) have pale greyish or yellowish-white bulbs, *L. Bloomerianum ocellatum* (a variety of *L. Humboldtii*) has purple-dotted bulbs very similar to those of *L. Browni* in colour and dotted in the same manner. The most delicate colour I have seen in any Lily bulb is observable in the fresh young bulb growth of *L. superbum*, where the white scales are suffused with soft rose colour; *L. canadense* and *L. pardalinum* have yellowish scales; while *L. canadense parvum* has scales as white as dogs' teeth, and not unlike them in shape, only much jointed. The curious and sharp-pointed scales of the bulbs of *L. avenaceum* (true) are clear yellow in colour, and being jointed in the middle the jointed part is readily broken in potting or digging up the roots, and then one could readily imagine that the husked fruit of Avena or Oats had become mixed with the soil. The white-flowered Lilies of the *L. longiflorum* type, such as *L. neilgherense*, *L. Wallichianum*, *L. philippinense*, the European *L. candidum*, and the Japanese varieties of *L. longiflorum* itself are somewhat similar in the shape and colour of their freshly dug bulbs, the form being the ordinary ovoid type, with white or pale yellow scales.

As to the uses of Lily bulbs, apart from their flower-yielding properties, but little needs to be recorded. The bulbs of *Lilium ciliosum* and those of *L. tigrinum* are eaten by the Japanese, who boil, roast, and preserve them in various ways. The bulbs of some of the American Lilies are, or have been, also frequently eaten by the Indians.

Structure of Lily Bulbs.

I cannot do better than quote Mr. Baker's summary of bulb structure from his "Revision of the Genera and Species of Tulipææ," p. 219, where the main points of interest are thus set down:—"Firstly, throughout the tribe the bulbs are strictly determinate and monocarpic, the main axis elongating into a flower-bearing stem, and the bulb, the cycle of existence of which is from one to three years, either dying or remaining, but in either case developing a new bulb in the axil of one of its scales. In what is called a perennial squamose bulb the

old scales remain, and a new bulb is developed into a flower-stem in their centre; in the third and fourth types the old scale or scales die, and the new floriferous stem is developed outside them. Secondly, we get in the tribe, side by side with a general uniformity of flower structure, every range of transition, from a typical squamose bulb (Lily) through a typical tunicated bulb (Tulip), to a tunicated corm (Erythronium), the difference between them depending upon the breadth and thickness of the enlarged bases of the leaves, their duration, their uniformity or difference in texture, whether they all, or some only, grow out to produce leaves aboveground, and whether some only, or all, are dilated below the surface into reservoirs of nutriment. Bulblets or bulbilla, quite similar in structure to those produced in the axils of the underground leaves, are regularly present in the axils of some of the leaves of the stem in *Lilium bulbiferum* and *L. tigrinum*, in *Fritillaria macrophylla*, and in the Mexican species of *Calochortus*, and are occasionally developed in some other Lilies if the inflorescence be injured." The nearest allies of the Lilies are the Fritillarias, which present two types of bulb culture—the one set, as in *Fritillaria Meleagris*, having a couple of thick, leaf-bearing scales or thickened petioles enclosed in two or three membranous tunics, "which have never produced leaves or fulfilled nutritive functions. This type of structure," says Mr. Baker (see "Revision of the Genera and Species of Tulipeæ," p. 216), "is scarcely varied throughout half the genus *Fritillaria*, and it is the type that is distinguished as having tunicated bulbs. But in the American *Fritillaria* there are no outside tunics, and the scales are numerous. * * * Upon this difference Dr. Kellogg has proposed to separate the American *Fritillarias*

Bulb of *Fritillaria recurva*.

as a genus under the name of *Liliorhiza*, but there is no difference in flower structure between the Old World and New World species, while the bulb of the New World *F. pudica* is sometimes barely distinguishable from those of the *F. Meleagris* group; and we get the *Liliorhiza* group represented in Asia by *F. kamtschateensis*; and in the Old World *F. imperialis* and *F. persica*, which were classed as Lilies by the pre-Linnean authors, we get a large, perennial, squamose bulb, without any tunic, not materially different in any way from that of *Lilium*, with the scales as thin, but not so regularly formed, and broader at the base; so that it will be seen that *Fritillaria*, which has been little studied from this point of view, presents great variety and much interest in its bulb structure, and runs over the line of transition which separates the squamose (or scaly) from the tunicated (or coated) type."

We may here again quote from Mr. Baker's "Revision of the Genera and Species of Tulipeæ," pp. 215-216, with advantage:—"The squamose perennial bulb is exemplified in all the Old World species of *Lilium*. This consists in its mature form of a large number of thin, flat, lanceolate or oblong-

lanceolate scales tightly pressed against one another, face to back, and spirally arranged around a central axis, which is not produced, either vertically or horizontally. From the under side of the central axis proceeds downwards a dense tuft of fleshy fibres, and from the upper side is produced the flower-stem of the year, its lower part, between the summit of the bulb and the surface of the soil, giving off copious radicular fibres, which assist greatly in procuring the nourishment and strengthening the hold upon the ground of the developed flower-bearing stem. This underground root-bearing portion of the stem above the bulb is often vertical, but in some species, as for instance *Lilium Leichtlini*, will creep for a length of 6 in., so that, if grown in a pot and the bulb planted in its centre, the stem will spring up from the side of the pot. [Mr. Elwes has seen this come up 2 ft. from the bulb, thrusting itself through a gravel walk. It should not be grown in a pot.] All these numerous flattened scales of the bulb possess potentially the power of developing new bulbs in their axils, and will do this, in some species at any rate, under cultivation if a bulb be broken up and properly treated; so that what with bulb-reproduction and what with seed-reproduction, a skilful operator may in three or four years multiply fifty-fold his stock of a desirable species or variety. But in a state of Nature there is only one new flower-bearing stem developed each season from the centre of the bulb and a few from the axils of the decaying outer scales. A new bulb, whether grown from seed or from bulblets developed in the axils of the aboveground leaves of the floriferous stem, or produced in the axil of one of the bulb-scales, takes not less than three years, under the most favourable circumstances, before it develops a flower-bearing stem. The first season we get an ovoid mass, perhaps a quarter of an inch in thickness, composed of half-a-dozen tightly imbricated scales, which sends out three or four slender radicular fibres from its base. At the end of next summer we have a bulb as large as a Hazel nut, with a copious development of strong radicular fibres from its under side, and the half-dozen scales prolonged above the soil into a rosette of oblancoate leaves. Next year, if circumstances be favourable, the flower-bearing stem is developed; and then, if nothing untoward happen, the bulb goes on living for an indefinite period, sending out each year a flower-stem from its centre and shredding off old scales with buds in their axils—more copiously in some kinds, less copiously in others—from the circumference all round. In two of the Californian Lilies (*Washingtonianum* and *Humboldtii*) this type of structure is modified by the central axis of the bulb being prolonged horizontally, so that the scales are thrown out of a regular spiral, and the mature bulb is irregular in shape and more or less flattened laterally. Here, then, we get a squamose bulb taking the first step to pass off in the direction of a true rhizome; but the fleshy scales are quite similar to those of the typical form. The direction of the rhizome is vertically oblique, the new scales being formed at the deepest end. [It may be observed that *L. Washingtonianum* loses its elongated or sub-rhizomatous character of bulb growth when cultivated in our gardens, the bulbs assuming a more regular or typical ovoid habit.] A second modification of this type of structure I cannot do better than describe in the words of Duchartre ("Observations sur le genre *Lis*," p. 25):—"To give an idea of this development, allow me to report what I have seen in *Lilium canadense*, as examined at the commencement of the month of March, and in consequence at a time when only the first indications of the vegetation of the year were observable. At the base of the stem, which had flowered the preceding year, and of which there remained only a small portion hidden in the ground, was found the bulb from which that stem had issued forth, a bulb formed of short scales, still fleshy and fresh for the most part, pointed and laxly imbricated, which, taken as a whole, was about twice as broad as deep. Immediately above this bulb was the remainder of the old stem, bearing a ring of root-fibres now dead and dried up. Finally, the extreme base of this same old stem was prolonged below the bulb with a diameter nearly double that which it had above; and after $\frac{1}{2}$ in. or more it ended by a broad truncation. It is from this old stem which has flowered in the preceding year immediately below the old bulb, and very likely from the axil of a scale

that has fallen, that the horizontal branch is originated, which at its extremity bears the new bulb from which the conical summit of the shoot, which will soon develop into the flower-stem of the year, is already seen to arise. This rhizome does not reach a length of more than 1 in. or $1\frac{1}{2}$ in. From its points of origin it descends a little into the soil, then raises itself to become horizontal, and finally rises at its extremity to form the axis of the new bulb, and to be finally continued as the new flower-stem. In its underground progress it bears small spiral scales, thick and fleshy, of which the first are slightly spaced, but those at the end of this subterranean branch growing closer and larger, and forming thus the new bulb. From the anterior portion of this rhizome, especially from the part that bears the lower part of the young bulb, arise numerous thickish rootlets, on the healthy action of which the vitality of the new vegetation evidently depends. Later on in the year the old bulb disappears, the horizontal rhizome thus becoming free. Then the rhizome dies in the part which does not produce rootlets, and at the same time a new rhizome arises from the base of the bulb of the year, to form in its turn at its extremity another bulb to yield the flower-stem of the year following. There are produced, then, in these Lilies a succession of subterranean bulb-bearing branches, or a series of successive generations, each of which has an annual bulb for its fundamental basis.

"In parting finally from this squamose type of structure I wish to point out that there are three different kinds of 'rhizome' in different species developed in connection with it, all of which are spoken of in books under the general term 'rhizome,' but which are not homologous, viz.:—First, the produced oblique central axis of the Californian Lilies; second, the lower part of the horizontal branch originating from a bud developed in the axis of a leaf-scale, which branch at its extremity bears a new bulb, as in *Lilium canadense*; third, the lowest part of the flower-bearing stem above the bulb when it creeps below the surface of the soil, as in *L. Leichtlini*."

One thing which has puzzled me a good deal in my studies among Lily bulbs has been the not unfrequent occurrence of jointed scales. This is constant enough to become quite characteristic in the case of *L. canadense*, *L. parvum*, *L. philadelphicum*, *L. avenaceum* (not in *L. Hansonii*, often until quite recently mis-called *L. avenaceum*), and one or two others of the American kinds. This peculiarity is, however, not solely confined to the American species, since the broad-jointed scales are found in one form of the extremely puzzling *L. davuricum*, respecting which Mr. Elwes has some curious information in store for us in his great work on Lilies, the appearance of which Lily amateurs and others are so anxiously awaiting. I was much perplexed, after having sketched a bulb of the proliferous entire-scaled form of this species in Mr. Barr's collection (and which he guaranteed true to name, having bloomed it), to find a totally distinct-looking bulb at Mr. Bull's with jointed scales, and of the identity of which its owner was equally confident as Mr. Barr had been. When Mr. Elwes called to see my original sketches of Lily bulbs, however, he relieved my anxiety by informing me that the proliferous form has long been grown in Dutch gardens for exportation to this country, and that formerly it was sent here as a substitute and under the name of *L. Catesbaei*. The other form with jointed scales appears to be the native condition of the plant, and blooms more freely than the proliferous form, otherwise flowers, foliage, and habit, excepting bulbs, are precisely similar. It is possible that a long course of culture by the Dutch florists may have induced this free production of offsets or bulblets at the partial expense of flowers, which are rarely produced, but on this point more information is desirable. The form of the scales of Lily bulbs varies from the ovate or bluntly lance-shaped scales of *L. candidum*, *L. auratum*, *L. speciosum*, and *L. longiflorum*, all representatives of what may be called the typical or ordinary ovoid Lily bulb, so often figured in botanical books through a series of bulbs, having more or less fiddle-shaped or constricted scales, as is the case in *L. Leichtlini*, *L. croceum* and its variety *L. croceum aurantiacum*, *L. concolor* and its varieties, *L. callosum*, *L. tenuifolium*, and also in *L. Brownii*. The bulbs, having broad panderiform scales, slide into the thick, narrow-scaled bulbs of the American Lilies, with distinctly jointed scales, through the jointed form

of the European *L. davuricum*, to which we have already directed attention. The bulbs of most of the American Lilies of the *L. superbum* type, are but one-jointed, and this led me to think that, instead of the leaf having been shed from the thickened petiole, as is so evident in *L. Catesbaei*, leaving a scar; the diminished leaf itself had become bulboid in like manner with the petiole. This view, however, does not seem to hold good, since in *L. davuricum* it is nothing uncommon to find some scales with two joints, and in the little American *L. parvum* three or even four joints are not uncommon. I am particular in pointing out this jointing, because I can find so little written on this point, which is one of much interest to the teretologist and structural botanist. The first reference I can find respecting the articulated scales of Lily bulbs is in the "Proceedings of the Academy of Natural Sciences of Philadelphia," for 1876, p. 412, where it is recorded that "Mr. Thomas Meehan remarked that some bulbs of *Lilium pardalinum*, received last spring from Dr. W. P. Gibbons, had the scales articulated in the middle. The upper portion of the jointed scale fell off easily at the slightest touch, giving the blunt ends of the remaining portion the appearance of grains of Indian corn as they were arranged along the rhizome. Dr. H. N. Bolander has since informed him that it was a common characteristic of this species. It does not, however, appear to have been noticed by monographers of this genus. He had since found that the eastern *L. superbum* had the same character; it was, however, by no means regular. Some bulbs would have a large number of articulated scales, while others had but a few here and there; and they were as likely to be found among the inner as the outer scales. The scales of Lily bulbs were but the dilated and thickened bases of ordinary leaves. There were no articulations in the normal leaves, and it was difficult to trace any morphological relationship in these scale joints."

Growth of Lily Bulbs.

The growth of Lily bulbs is a matter of great importance to the cultivator, and it is now fairly settled that outdoor culture—the bulbs being planted in the open border—is best for the majority of Lilies, the only exceptions being perhaps *L. philippinense* and its late-flowering Indian ally, *L. Wallichianum*. A deep, rich, sandy loam, on a gravelly bottom seems to suit all the strong-growing European Lilies, and also the more robust of the Japanese kinds. *L. auratum*, *L. speciosum*, *L. testaceum*, and even the creamy-tinted, wax-like *L. neilgherrense* grow well, perhaps best, in the cool, deep, peaty soil of Rhododendron beds in positions sheltered from rough winds, and where they receive copious supplies of water during hot summer weather. Mr. McIntosh adopted this last system of culture some years ago, and every one who has stood beneath his 11-ft. high clumps of *L. auratum* will agree with me that for *L. auratum* no other system of culture is nearly so good. A third group of Lilies, such as *L. canadense*, *L. pardalinum*, *L. superbum*, and their varieties, may be designated "bog Lilies," since they like a rather wet, peaty compost, or perhaps I should say the comparatively dry banks of a stream, where their roots can descend to the moisture when in full growth. *L. neilgherrense*, *L. Wallichianum*, *L. philippinense*, and one or two others, although doubtless quite hardy in sheltered positions on warm, dry soils, can scarcely be looked upon as likely to make a perennial growth in the open air generally, and had perhaps best be treated as pot Lilies, or better still, they may be planted out in the light, rich border of a conservatory from which frost is excluded. The growth and functions of Lily roots are so well described in Dr. Wallace's "Notes on Lilies," that we cannot do better than quote the following on the subject:—"If a healthy Lily be examined two sets of roots will be seen, one set proceeding from the base of the flower-stem, and the other set from the base of the bulb. These roots in a healthy-growing plant are very abundant, and may be described as forming a wig. Now if the stem be detached from the bulb and planted with its roots undisturbed it will flourish and flower vigorously, and may perhaps, if there be time before autumn sets in, form small bulbs at the base of the stem to perpetuate itself, otherwise it dies, but not until the season is over. If this operation of transplanting be carefully performed it is impossible to detect any check to the foliage

and flowers. Again, Lilies may have their stems damaged, eaten off, or destroyed in various ways, or for some cause or other may remain dormant for a whole season, but it does not follow that the bulb itself is injured, since the roots at the base of the bulb are put forth as usual, and the bulbs grow as well, or even better than they would if the stem were normally produced, since there is no stem to rob them of nourishment. We have known an instance where, although no growth was produced aboveground, the bulbs which had been supposed to have perished were in the autumn found to be much larger than when planted in the previous spring." As a rule, of course all additions to the weight of bulbs are due to the action of the foliage, but, as we shall see presently in the case of *L. neilgherrense*, a bulb may grow and form young bulbs out of its own substance long before the end of the stolon or underground stem has appeared above the ground, and when the old scales of Lily bulbs are used for propagating purposes, this growth, or rather change of form and substance, takes place to a considerable extent before any foliage makes its appearance, the inherent growth power of these bulb-scales being closely analogous to that of seeds. It will be seen that the growth of a flowering bulb of a Lily is more complicated than that of a non-flowering bulb, since in the latter all the root-power of the plant is expended in taking up nourishment for the enlargement and fattening, or plumping out of the bulb; but in the case of a flowering bulb, there is a struggle continually going on between the flower-buds, flowers, and seed-pods, and the bulbs, as to which shall obtain most of the nutriment collected and elaborated by the roots and leaves. Thus, as Dr. Wallace informs us on p. 6 of his "Notes on Lilies," "it is possible for the bulb to be itself absorbed by the act of flowering," and this is nearly always the case when flowering bulbs are planted in small pots of poor compost, or in any medium which cripples root-action. Lily bulbs should never be dried off like Hyacinths and Tulips; their scales should never be allowed to become dry, since any part of their weight or substance lost by evaporation weakens the bulbs in inverse proportion. If Lily bulbs be planted in deep, moist, well-enriched, porous soils, their bulbs increase in number and bulk, and this will be found to be especially the case in those of the *L. bulbiferum* and *L. Thunbergianum* types. Apart from increase of bulk by division, however, Dr. Wallace informs us that "a yearly increment of growth occurs in the smaller bulbs in the centre; the outer and old scales are pushed farther apart by the new growth, and the bulb increases in size more or less according to the nature and health of the bulb. In choosing bulbs, therefore, in addition to preferring a hard, weighty bulb, choose also one that has a light coloured plump interior or "heart," showing good recent growth for next season's flowering. We were particularly led to these observations by noting some bulbs of *L. Browni* which had grown well last year but did not flower; the bulbs were half as large again as when planted, the interior was filled up with light-coloured new scales, outside of which were a few discoloured scales evidently of former growth." Therefore, when we hear it said that a Lily bulb takes a year to recover itself after importation or transplantation—[which, however, but rarely occurs in the case of *L. auratum* and *L. speciosum*, although *L. pardalinum* and *L. Humboldti* frequently fail to bloom the first season after importation]—this really means one of two things—namely, either during that time an offset has been developed (from the bulb planted) to the flowering stage, or an increase of heart-growth has taken place in the interior or "heart" of the bulb planted, from which the flowering stem rises the second year after planting; and one or other of these processes is what generally takes place when bulbs have suffered in transplantation; but imported bulbs, if of good size, generally bloom the first year, unless they are kept out of the ground too long and become shrivelled—a sure indication that much of their substance has been lost by evaporation, and so weakening is drought on Lily bulbs that a plump, fleshy bulb the size of a Walnut will produce a much stronger flower-stem than a large bulb, the scales of which have become shrivelled and flabby. Mr. Barr tells me that one season the late frosts destroyed the young growth of some of the bulbs of *L. testaceum*, and they were thought to be dead. The bed where they were planted was used as a

barrow path, and in the ensuing autumn, when the path was dug up, the bulbs were found quite fresh and plump, being, in point of fact, much finer than others which had not had their growth injured. This leads us to the question whether we might not with advantage grow two sets of all our fine Lilies, allowing each set to flower alternately. At any rate, all the evidence we have on this phase of Lily growth goes to prove that we might advantageously strengthen our imported Lily bulbs by topping the flower-stems so as to prevent the production of flowers even if we did not, spring-frost-like, destroy the growth altogether for a season. In the autumn of 1876 some bulbs of *Lilium davuricum* in Ware's nursery at Tottenham produced secondary stems bearing flowers and buds (blanched and misshapen, of course) underground, concerning which Mr. Perry gives me the following particulars:—"I have succeeded in finding a specimen of the Lily this morning; a few weeks ago I could have found a more perfect

Anomalous growth in *Lilium davuricum*.

one, having the flowers and leaves more fully developed. Last autumn I removed my two-year-old beds of *Lilium davuricum* in variety, and in the majority of cases I found specimens similar to the one sent; some, through the ground being hard and dry, could not attain a perpendicular position, but grew round the bulbs, grasping them so tightly that you could not move them without breaking. The beds in question had been planted two years, and were fine bulbs to begin with, and they all flowered the first season and then divided, forming one and two bulbs. The second season they flowered well, and some of the commoner sorts were selected to supply cut flowers. It is to this fact that I attribute this peculiar freak: I observed that after cutting off the entire head of flowers with some 6 in. of stem, that the remaining portion of the stem soon died, just in proportion to the length of the stem cut. If the head of flowers and an inch or so of the stem only were cut, the remainder lasted much longer, and in some cases died off naturally, *i.e.*, at the same time as those which had not been cut; I find if the flowers are nipped off individually, one may get very

fine bulbs, but I believe in all cases where the flowers are ruthlessly cut, we get emaciated bulbs, or, as in this case, start the maiden bulbs into growth prematurely. This second growth may have been accelerated by the hot weather followed by showers just about the time the bulbs were dying down. In all cases that came under my observation the second growth was made by maiden bulbs which were attached to bulbs which had flowered. I dare say I found 200 or 300 bulbs similar to the one sent; in nearly all cases I broke the stem clean out; I find they are forming a new shoot from the base of the old one, but I do not expect they will flower." In connection with our present subject, the following observations on the bulb-growth of Lilies by Dr. Wallace will be read with additional interest, coming, as they do, from one who has such excellent means and powers of making judicious comparisons:—"In purchasing Lilies I should like to give my orders very early in the season, and I should request that none of the roots be cut off the bulbs, but that they should be sent to me freshly taken up and packed in some moist material. Indeed, some of the Dutch growers recognize this, for though they expose their roots intended for sale to the action of the sun and air to dry the bulbs and give them a colour (according to the custom of the trade), yet they require that the bulbs they purchase shall be supplied to them quite fresh and with the roots uncut. Of course with imported bulbs this cannot be; but it is manifest that a bulb planted (say in October), rooting and drawing its supplies of nourishment, must be in a far better condition to support active growth in early spring and develop a fine head of flowers than one planted in January or February, kept dry all the winter, having hardly time given to it to emit a few roots before the stem shoots up and development progresses at a rapid rate. All Lilies ought to be in their places, where they are to remain, by the end of October. A third point I wish also to mention, which I have not solved to my satisfaction, and on which I shall be glad of further information from other cultivators. Do Lily bulbs make fresh growth every year, the old growth decaying more or less, as does the Crocus? I submit this question for future decision, merely advancing a few observations bearing upon it. (1) When the stem shoots up from the centre of a bulb it opens up and widely separates the old scales and much enlarges the size of the bulb. I have been surprised to find bulbs, under such circumstances, of the size of a medium Orange when in flower, though when planted they were only as large as a five-shilling piece. (2) Fresh growth, recognized by its white, fresh, firm appearance (light not yet having coloured it), takes place inside the bulb, pushing out the old discoloured scales. In such kinds as *longiflorum*, *speciosum*, *auratum*, and *Martagon*, where the colour of the scales is well marked, I have seen many bulbs, freshly dug up, entirely composed of new growth, a few only of the old scales remaining. (3) When Lilies degenerate, as they often do in pot culture, they get smaller and smaller every year; the tints of their flowers also degenerate. Now in this case is it not because the new growth, under unfavourable circumstances, becomes smaller and smaller each year, till at length it ceases altogether, and the bulb dies? The same thing also happens to many bulbs grown out-of-doors in unfavourable conditions; they get weaker and weaker every year till they die, unless removed to a more suitable spot. I should much like to watch some Lily bulbs grown in a glass pot planted against the side, so that all the processes of growth might be watched. (4) Amongst the North American forms with rhizomatous bulbs, such as *superbum*, *puberulum*, &c., fresh growths are emitted every year in the form of buds or stolons; from these the flower-stem shoots upwards in the following year, so that each year there is a succession of new growth. From these considerations it follows that well-chosen bulbs planted early must be in the most favourable condition to flower freely and make good growth the succeeding year, producing a fine display of highly-coloured blooms. Hence the following rules:—(1) Plant deeply—say 6 in. to 8 in.—so that the roots may easily get into a moist sub-soil, and be sheltered from the scorching, drying influence of the sun's rays. (2) Plant early in the autumn, so that the roots may be at work all the winter. (3) Choose fresh, undried bulbs, with if possible new white central growth, whose roots have not

been cut off or dried. (4) Plant in a cool, shady border not exhausted by roots of trees, where the roots may always obtain moisture and yet not be saturated, where the surface of the ground is shaded from the sun's rays, and yet where the buds and leaves may enjoy sunshine to perfect the flowers, such, for instance, as a sloping bank, with water percolating its sub-soil, with a south-eastern or south-western aspect in our southern counties, and with a more southern aspect as we go further north. Carpet the soil with low-growing foliage or flowering plants, such as *Rhododendrons*, and, in the absence of anything better, use *Mignonette* or *Chickweed* rather than allow full exposure to the sun's scorching influence. 5. During the growing season—*i. e.*, from the time that the stem pushes aboveground up to the time when the flowers begin to open, let an abundant supply of moisture be provided. In India they have their rainy season, during which *L. Wallichianum* shoots up aloft; in Japan they have abundant rains during May and June from six to eight weeks; this, coinciding with my own experience, makes me confident that, drainage being provided, we can hardly give too much water at that season. (6) Where Lilies are grown in pots it will be found advantageous to protect the upper roots by placing masses of fibrous peat and loam on the surface of the pot. (7) If pots be used—and they can hardly be avoided for some kinds (and that Lilies can be well grown in pots the practice of Mr. Wilson amply proves)—then large pots must be used to provide abundant room for root-action—pots with straight sides and broad bases are, for the same reason, better than those with narrow bases; and abundant moisture must be provided daily during the period of growth. (8) The Japanese plant sideways, to prevent the wet lodging between the scales and rotting the bulbs."

The advice given by Dr. Wallace as to the use of large pots requires some qualification. For example, if a small bulb be placed in the mass of soil contained in a large pot, the chances are that much of the soil will become sour before its rootlets reach the sides or bottom of the pot, and then the decay of the root-fibres is the result. Mr. G. F. Wilson suggests that after having well drained the pot, it should be filled with peat and fibrous loam in layers, since the Lily roots feed on the loam greedily, which in its turn is kept sweet and fresh by the antiseptic property of the intervening layers of peat. Mr. Barr uses half-bushel pots, about one-third of their depth being filled with an inverted pot and abundance of crocks, and eight or ten good bulbs of *L. Humboldtii*, *L. neilgherrense*, or other Lilies are then planted in a fresh, porous compost of fibrous loam, leaf-mould, peat, and sand, the result being that the body of soil, although large, is soon filled by healthy roots, and is prevented from becoming soddened by the ample drainage provided. The cool bottom, so essential to the well-being of all Lilies, is provided by placing the pots on moist soil mulched with *Cocoa-nut* fibre or spent tau. A more copious supply of water is requisite in the case of pots drained as above described, but it is far more easy to give plants water or liquid manure than to remedy any injurious influence exerted by stagnant or soddened compost. It may be safely said that no Lily bulb blooms twice from the same centre; and although most of the Japan Lilies seem to produce flower-stems from the same bulb (on closer examination we find that the flower-stalks spring from new buds formed within the old bulb every season), they are, in fact, new bulbs formed within the parent one, but remain attached to the same base, drawing in part sustenance from the surrounding scales, which are only undeveloped leaves. The common American Lilies, such as *L. superbum*, *L. canadense*, and *L. philadelphicum*, found growing in low meadows are perpetuated in quite a different manner. The bulbs are produced on large subterranean stems growing a few inches below the soil. This stem lengthens and produces one or more new bulbs every year, those formed the previous year blooming but once, then commencing to decay, their substance being attracted by the younger growth. In digging up one of these Lilies we sometimes find a string of bulbs of various ages all attached to the creeping stem, but only the last-formed or youngest will bloom after transplanting. Other species of bulbs and tubers increase in a different manner, each having peculiarities or individual characters of its own, although all obedient to a general and similar law. If we, therefore, only study that portion of the vegetable king-

dom which is seen aboveground, one-half is overlooked, for it is not unfrequently the case that the most interesting part is hidden in the earth.

"Let us in the first place," says Dr. Kellogg, 'consider the Lilies how they grow.' In a climate like that of California, distinguished by a wet and long dry season, we find these bulbs located, say about 6 in. to 10 in. deep, and the fibres or roots shooting downwards 10 in. to 12 in. below that point, in search of food and moisture. Is it not evident then, that such bulbs require a flower-pot at least 18 in. deep? Hence ordinary pots must be utterly useless, or worse—cramping or inadequate to meet even primary natural conditions. Let any one take an improvised 5-gallon tin can, or the like, which is good enough, not to say the best; paint it rudely inside and out to preserve it; punch, say at least three large holes in the bottom of it; plant, as in Nature, in any good compost, and set your can, keg, or crock, as the case may be, in a shallow pan of water. You will soon have the pleasure of seeing a stout stem of the thickness of your thumb rising up and flowering gorgeously. If a plant spend its vital force in vain searching for food or moisture, little or nothing else can be accomplished. Cultivators are apt to complain that many of their bulbs ere they bloom lose one essential beauty of plants, viz., their radical leaves, which they say 'dry up and leave the stems looking naked and bare.' Bulbs are frequently found upon exposed hills and slopes, rocks, &c., descending down dry and very hot valleys into débris and alluvial bottoms, where sand and loam, with underground moisture, abounds. The very same plants are seen to rejoice best where they find some shade and shelter, otherwise they bespeak a struggle for existence—i.e., their leaves prematurely or naturally dry up early to save exhaustion. What lesson do such facts teach? Surely that the cultivator should imitate Nature in her best aspects, and it is by no means difficult to exceed even her highest standard. Bulbous plants form no exceptions. It would indeed be folly to fold one's hands at the very first failure; and with what delight do we behold one joyously filling up the full measure of its glory! In the loose soils in which we usually place our bulbs, are they as well situated as in their native matrix? The soil then must needs be packed firmly and uniformly. It is the life-struggles with difficulties to be overcome that bring out the best qualities of the man—the fruits and flowers, roots and bulbs, born of the great mother. Resistance above reacts below, gives spread, depth, and vigour in the direction of least resistance. The root—the strong foundation—is of first consideration in all structural buildings, and should be well laid, cherished, and preserved. We do not say it should be founded upon some suitable rock, but we sometimes think so; radiated heat and graduated temperature, sweetness of drainage, and it would seem reasonable that in due time some resistance from below also, are all requisite of high culture. May not the cultivator, in his nude solicitude, be also to blame, and by some shortcoming fail, or from excess undo, by overdoing? Suppose he flood too continuously between loose scales, adding excessive heat withal, ought not he to expect just the result urged? Now we seldom see in Nature bulbs sheltered by shrubs, rocks, logs, bark, leaves, &c., or in very compact soils rotten at the tips of the scales, and hence a lure to maggots and grubs; nor often in such sandy and gravelly soils as readily absorb, drain, and disperse any excess of top moisture. We appeal to the observations of careful collectors. Let us then copy the best conditions, and we feel assured the result will confirm our rather hasty hints. In conclusion, we dare not presume that even a tithe of what we ought to say has been noted; in short, we have confined ourselves only to what may be considered peculiar to climatic conditions. Erudite and complex recipes relative to proper mixtures of soils, and common management may well be left to the knowledge and judgment of those who believe in them. With such a wealth of sunlight and heat above as falls to the lot of California, and no lack of the necessary medium moisture below, I see no reason why we may not allure Nature under human hands to grow her fragrant white Lady Washington Lily 6 ft. or 7 ft. high, with ten to thirty or more flowers, just as we see it wild. *L. Bloomerianum*, too, is a perfect giant among Lilies, when at its best making a right super-royal display. Even our little orange *L.*

parvum I found at the Sierra summit, over 5 ft. high, and bearing fifty flowers carefully counted; but the plant was sheltered and shaded by an old emigrant water-tank stilted up, now dry, and long ago abandoned; but its roots found a fair supply of water from beneath."

Increase of Lily Bulbs.

Bulbous plants possess an advantage over many others, inasmuch as they are able to reproduce themselves or even increase themselves without the aid of seeds, notwithstanding which fact, however, the latter organs are in most cases very freely produced, and this is especially the case with Lilies. Apart, however, from the natural processes of division and seminal reproduction the cultivator enhances the multiplication of these charming flowers by layering the flower-stems (after having removed the flower-buds) in light, moist compost, and thus facilitating the production of the axillary bulbs, which in the case of *L. bulbiferum* and *L. tigrinum* are plentifully produced without any artificial assistance whatever. It is now well known that by removing the flower-buds of Lilies as soon as they appear a much larger bulb-growth is obtained; but it does not appear to be so generally known that this removal of the flowers tends greatly to promote the development of axillary or stem bulbs, and especially is this the case if the flower-stems be layered in leaf-mould, or any other light, moist compost calculated to foster the growth of the little bulblets after they appear. One Lily at least (*L. neilgherrense*) naturally adopts this method of reproducing itself, as will hereafter be illustrated, and there is no artificial method of Lily propagation more deserving of notice than this by amateurs, especially as it is, after seeds (and raising seedling Lilies is a long process, as one must wait from three to ten years ere they bloom), the only method of propagation which can be carried on without materially weakening the flowering bulbs. Another excellent plan of propagation, and one long practised by the Dutch bulb growers, is to strip the scales off old bulbs and plant them in light, rich soil, after which they are treated much in the same way as bulbs raised from seed, but they come into bloom at least a year sooner. The following remarks on the treatment and increase of Lily bulbs, contributed by Mr. Frank Miles to THE GARDEN in 1875, will be read with much interest in relation to our present subject:—"Let us begin with the commonest and most ill-used of all Lilies—the common White Lily—*candidum*. We have here a large quantity of it in very big clumps, but from some cause these have never succeeded as they ought to have done, only every fourth or fifth maturing a flower-stem. As soon as they had done flowering, when the stems were beginning to get dry in the end of the month of August, I took up all these clumps and separated the bulbs. I found then that the greater quantity of the bulbs had no roots at all, in fact, wretched little slugs had eaten them off close to the bulb as fast as they grew. After separating and cleaning each bulb I put them into a tub of soot and water for two days to kill any embryo slugs that might have escaped my notice. I then planted the whole in a row 5 in. apart each way and 4 in. deep. Half the row was strongly dressed with soot and half with lime. Another row had no lime or soot, except what they retained from the tubbing. I took up some of the last row the other day and found my friends the slugs calmly browsing on the newly-formed roots as calmly as if soot were not an infallible preventive against their ravages. On lifting those dressed with lime I found the bulbs firm and growing fast with long fleshy roots. It is certainly marvellous how quickly these Lilies reproduce themselves; each scale which has been injured in separating the bulbs has now at its base a small offset about the size of a Cobnut. Some bulbs of *L. chalconicum* that were left in the potting-shed have produced from twenty to thirty small offsets whenever they were bruised. Since writing the above I have searched in the Grass for any scales of the white Lily that were lost when we pulled them to pieces. I found a good many scattered about, and nearly all had on them bulblets of the size of a large Pea entirely formed since the end of August, and that, too, when merely protected by long Grass. I have this afternoon been digging up in a neighbouring nursery about three dozen bulbs of *L. auratum*.

Many of the bulbs were planted late and flowered indifferently; but, on taking them up, we found some of them had as many as twenty small offsets. The thirty-six have given me more than four hundred offsets, some the size of a Cobnut and some about half as big as a Pea." Mr. Barr tells us that in December, after overhauling his stock of *L. auratum*, and taking out the best bulbs, the defective ones remaining were thrown into a large basket with a little Cocoa-nut fibre, placed in a shed, and left until March without being disturbed, at which time they were one mass of young bulblets, thousands having been produced by the old, partially-decayed scales, each little bulblet bearing one or two green leaf blades.

TREES AND SHRUBS.

EVERGREEN UNDERWOOD.

THE above term is commonly employed to denote such trees or shrubs as grow naturally, or are planted for covert about the woods under the shade of the taller forest trees. The species that thrive in such situations are not very numerous, for there are not many trees that grow well in the shade, and some of those that do grow those depredators, the rabbits, may frequently destroy in hard winters. Besides, there are some species of forest trees under which scarcely anything will grow, owing partially to the density of their shade and their habit of rooting near the surface of the ground. Of this class is the Beech, which is, perhaps, the worst of all. Under a group of Beech trees the ground is as often quite bare as otherwise, and it is needless to plant under them. In Oak and Ash plantations, however, there is always plenty of undergrowth, and in mixed plantations generally there is not much difficulty in getting up a good covert. Oak woods, or woods consisting principally of deciduous trees, have a naked and dreary aspect in winter if they be not relieved by evergreen undergrowth of some kind, and it is not often they are furnished to any extent in that way. Sometimes a few Spruces or Scotch Firs afford here and there a little shelter, and impart a warmer aspect to the scene, but some have an objection to these, and they are the first to be removed when thinning takes place. When travelling by the train miles and miles of woods may often be seen in which hardly a green leaf is visible during the winter months. How different the aspect of things when the wood happens to be well sprinkled with green Holly trees! and there is no better subject than the Holly for such a purpose. We have seen a wood completely transformed in its winter aspect by planting it with Holly. When the tall trees were leafless, and the Bracken brown and dead, the Holly shone out green and glistening in all its beauty. Besides, it has a recommendation from a sportsman's point of view. The Holly is a warm tree, and the birds flock to it in winter, especially the sparrows. When snow is on the ground, if there be a bare or warm spot in the wood, it is under and around a Holly tree. The snow always melts away near it, and at such times you are almost certain to start two or three pheasants from amongst its lower branches if there be any pheasants in the wood; this we have observed many a time ourselves, and gamekeepers will tell you the same story. Where game is reared, therefore, we should say the Holly is one of the very best subjects to plant as underwood; there are none more suitable, for it stands shade better than any other evergreen. The Common Laurel grows tolerably well also, but straggling, and it should be cut down occasionally: rabbits do not eat it, and it affords them excellent shelter. The Rhododendron, of course, is well known for being almost rabbit-proof, and it also grows under the shade of other trees, but it must not be expected to flower freely in such quarters. The Yew is another tree that grows pretty well in the shade, though it gets thin in the branches in the course of time. Nothing approaches the Holly, however, and it soon grows to a large size. Unfortunately, the rabbits often bark the small plants, but I have not seen them meddle with anything but the outside branches of the older trees. Where rabbits are to be feared planting should always be deferred till April or May, when all danger from their attacks is over; besides, that is the best season to

plant Hollies. Tolerably large plants with bushy bottoms are preferable to those of other shapes for planting in the woods. For this purpose the best plan is to grow the trees in the home nursery for a year or two, giving them plenty of room, and afterwards remove them to the woods. They may be planted anywhere under the trees, but at the same time the most favourable spots as regards light should be selected for them.

S. S. W.

Euonymus europæus and other kinds of Spindle Tree.—"*Salmoniceps*" (see p. 26) deserves thanks for directing attention to *E. europæus* as an ornamental berry-bearing shrub, which, indeed, is not the only representative of the genus which we should have in our shrubberies, for *E. americanus*, *E. angustifolius*, and *E. atropurpureus* are also all highly deserving of cultivation. Equally valuable, too, are the varieties of the common Spindle tree (*E. europæus*), particularly the white-fruited sort. They are all highly interesting, and their opening capsules look really beautiful, especially as they occur at a time when other plants are losing, or have lost, their attractions. During the past autumn and winter (particularly about Christmas time) I found them invaluable for various decorative purposes. The branches on which the fruit is produced are so flexible that they can be arranged with other plants with the greatest facility.—E. R. Q. P.

Hemlock Spruce Hedges.—I have often wondered how such fast-growing evergreen trees as the Hemlock Spruce and Lawson Cypress were not more frequently employed as evergreen hedges. I had several Lawson Cypress hedges made in the kitchen garden here to shelter the vegetable crops, and they soon got to the size required, and bore well the cutting and clipping to which they were subjected to keep them in shape. Hemlock Spruce I have no doubt would answer the same purpose, and when tried, both in the case of it and the Lawson Cypress, young plants should be selected so as to start with a bushy form. The soil should be trenched, and if strong, it should be enriched with peat or leaf-mould so that the plants may have a good start, when success would be certain.—W. TILLERY, *Welbeck*.

Scarcity of Holly Berries in Ireland.—At various points along the valley of the Blackwater from Mallow to Lismore, Hollies prevail to a large extent, and trees of them that are generally laden with berries, so much so as to remind one of the Common Hawthorn, are this season literally without fruit. I cannot, however, agree with Mr. Darwin that this general failure is to be ascribed to a lack of bees; on the contrary, like Mr. M'Nab, I can only attribute it to the severe frosts which were experienced in April and May last year, and even to some extent in June, for though the winter of 1875-6 was comparatively mild and open, in spring we had frost, and to this cause (the Holly coming into bloom early in May) and to no other the almost total absence of berries is doubtless attributable. Apples and Pears, too, suffered much from the same cause, though, as far as bloom went, nothing could have been more promising. I never recollect deciduous forest trees being so late in putting on their spring garb as they were last year, and the result was that the beautiful soft green of the Beech and other trees, that are often burnt up by too early a leafage, escaped quite unscathed. Up to the present time we have had nothing but strong winds, rain, and floods. I much fear, however, that "winter will be lingering in the lap of May" this year like the last, and doing work anything but agreeable to the horticulturist.—E. R. Q. P.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Quercus Mirbecki.—This is a remarkable and handsome species of Oak, a native of Algeria, which may now be seen in full leaf in the Garden of Plants, Paris. It has somewhat the look of a deciduous Oak, and the leaves are large. What a wonderfully rich and varied family of trees adorn in such profusion the plains and mountains of both the Old and the New Worlds!—W.

Ivy as a Carpet Under Trees.—We some time ago directed attention to the value of the common Irish Ivy for clothing the ground under trees on lawns where Grass refuses to grow. How efficient Ivy is for the purpose named is forcibly exemplified in the pleasure grounds at Guernersbury. In these beautiful gardens are several grand old Cedars (*Cedrus Libani*), and beneath them, as far as the branches extend, the ground is closely covered with Ivy, which is perfectly green and fresh under the dense shade, and adds considerably to the effect and finish of the grounds. These large circular beds of Ivy are quite ornamental, and decidedly enhance the beauty of the old trees. The labour of patching the turf under trees on lawns many cultivators know to be considerable, but when once the Ivy is established only a very small amount of labour is required to keep it in order for years. The subject is highly worthy of being again alluded to, and of being kept in remembrance.—"Journal of Horticulture."

IVY IN PARIS.

ANY ONE in the habit of traversing the streets of the better parts of Paris sees many evidences of the graceful way in which the common Irish Ivy is used to embellish the courtyards, the railings, the walls, the villa gardens, and the public gardens of that city. It would be difficult to give any adequate idea of the charms added by this means to many surfaces that would otherwise be hard and bare. In any city or town where the air is not much polluted by smoke, the same effects may easily be produced. In cold districts, where Evergreens are scarce or liable to suffer, it is all the more desirable to make judicious use of the most valuable of all evergreen climbers for northern countries. The figure here given repre-

NEW HYBRID RHODODENDRONS.

To the late Mr. John Standish we are indebted for some of the best of our hybrid Rhododendrons. His attempts at crossing these plants commenced some twenty-five or thirty years ago. A score or so of years previous to that there could be found among the various shades of Rhododendron catawbiense, which was then being raised from seed, varieties approaching white in the colour of their flowers, such as *R. album elegans*, *delicatissimum*, and others. These Mr. Standish commenced crossing with *R. pictum*, and other spotted kinds, which produced the well-known *R. Minnie*, a very late bloomer, and a batch of fine white varieties. A few years later he took *R. Bodaërtianum* and *R. cinnamomeum*

Ivy Bower grown from one Central Stem.

sents a bower formed of Ivy trained to one stem and grown in a tub; it may be considered among the curiosities of Ivy culture. It is common in Paris to have railings and wall-surfaces far above the ground-lines covered with fresh Ivy, and in such cases it has of course to be grown in boxes or the like in rich soil.

The Sarsaparilla as a fine-leaved Plant.—We have lately been much impressed by the rare beauty of form displayed by the leaves of this plant trailing over arches, &c., in one of the stoves of the Paris Garden of Plants. The leaves are large enough to resemble those of some tropical Arums, but more beautiful in form, and the shoots grow many yards in length, producing leaves equally fine all the way. Probably if a great number of shoots were allowed to rise from the root, the foliage would not be so fine. Those having large, warm houses to embellish may use similar Sarsaparilla with advantage.—V.

Cunninghami, and crossed them with *R. Minnie*, all being more or less spotted. His aim was to obtain some late-blooming white varieties with spots on the flowers; and the result more than exceeded his expectations, for not only did he succeed in raising varieties that flowered all through June, and that were handsomely spotted with almost black, chocolate, red, maroon, and various other colours; but he also obtained red, chocolate, and almost black blotches on a pure white ground, nearly as well defined as those on a show Pelargonium. In one of his latest seedlings belonging to this race, viz., *La Baronne Isabelle de Taintignes*, the blotches were very conspicuous indeed. Another interesting cross was that obtained from *R. Blandyanum* crossed with *R. Thompsoni*, one of the Sikkim varieties, the flowers of which are all pendulous and

small in size, and yet, strange to state, some of the hybrids thus obtained had flowers larger than those of *R. Blandyanum*, and one of them, named on account of its striking colour *Ascot Brilliant*, had flowers of the most intense shining blood red. About the same time there also bloomed at the *Ascot* nurseries some very fine red varieties raised from *R. Brayanum* crossed with *R. Minnie*, and *R. Johnsoni* crossed with the same variety. One of Mr. Standish's latest crosses was made between *R. Aucklandi* and some of the best of his late-flowering white varieties. When I last visited *Ascot* in his lifetime he had plants so obtained from 12 in. to 15 in. in height, and he hoped to have bloomed them in two or three years from that time. These seedlings, in the character of their foliage, appeared to be as near as possible between the two parents. Several attempts were made to cross some of the smaller-flowering sorts with the pollen of *R. Aucklandi*, but to no purpose, the failure being attributed to the pollen of *R. Aucklandi* being too large for the tubes of the pistils of the smaller-flowered sorts. One fact which Mr. Standish had deduced from observation he was very fond of impressing on visitors to the *Ascot* nurseries, namely, that in spring, when the early-flowering *Rhododendrons* were in bloom, and there happened to be a frost, the nearer the varieties were to *R. arboreum*, the more were they susceptible to the effects of the frost, while, on the contrary, the nearer the race was to the Caucasian species, the better were they able to resist the destroying influences of frost.

At the time when these crosses were in course of trial the beds of seedling *Rhododendrons* at *Ascot* possessed a peculiar interest. Beds were specially prepared with very fine soil for the reception of the seed; they were between hedges of *Arbutus* to keep them cool and shady, and the rule with Mr. Standish was to have the hedges running from south to north. The hedges being 8 ft. apart admitted of a bed from 2½ ft. to 3 ft. in width, and a gangway back and front for weeding, &c. The seed was sown in the month of June, a slight sprinkling of water given, and a thin layer of *Heath* added to protect the newly-sown seed from the sun's rays. Three or four times during the summer they received a good soaking of water, and in August or the month of April following, the seedling plants were pricked out into pits about 9 in. below the surface, and the plants were set 3 in. apart in the rows. After being pricked out the lights were placed over the pits, and then removed as the summer advanced to make the plants as hardy as possible. They were wintered in these pits, and the following April many of them were large enough to be put out in beds to bloom.—D.

STANDARD ROSE TREES ON LAWNS.

GROWERS of standard Rose trees often complain that they cannot get them to live. Many reasons can be given why standard Roses die off prematurely, but the main one is that suitable varieties are not got from the nursery. An order is sent to the grower that certain varieties are wanted in the form of tall standards. It is thought that every Rose will grow on a *Brier*. Why not? Why should not all Roses grow alike? It is not imagined that the *Brier*, being of a robust nature, requires a robust-growing Rose to be budded upon it. Weak-growing Roses require a dwarf stock. Vigorous ones will grow on a 4-ft. stock, and will live a good many years. In order to get standard Roses to live and flourish, it is necessary, in the first instance, to go to a nursery and pick out one's trees. There may probably be a trifle extra to pay, but plants should be chosen that have been grown two seasons after being budded; they should have compact and moderate-sized heads, and care should be taken that the growth has been vigorous and healthy. Look well at the roots, and see that there is plenty of fibres and no large knobs. Reject all having a large knob or clump at the roots; it denotes old age and a plentiful supply of suckers in an incipient state. Examine the stem of the *Brier* to see that it is clean and free from bruises, which are often caused by the bites of rabbits and sheep during severe weather whilst growing in the hedgerows. The next point is to know the habit of the Rose budded upon the *Brier*. Should the variety happen to be a weak grower, no head of any size can ever be formed on it, and its life will be a short one. On the contrary, should its habit be vigorous, with a free-blooming tendency, that Rose tree may live for many years. If tall standards be desired, the only safe plan to prolong their existence for a considerable time is as follows:—Dig out a good-sized hole in the lawn (say 3 ft. square and 2 ft. deep), remove all the bad soil and rubbish, and fill up with a rich compost consist-

ing of decayed turf, rotten manure, and ½-in. bones. Let the holes be already prepared; then plant the standards, tread the roots firmly in, and secure the stems to stout stakes with Cocoa-nut bands. Roses of a robust-growing habit will live a great number of years if planted in the way just stated. When a standard Rose tree dies, the cause in most cases arises from a weak Rose having been budded on a tall *Brier*, and sometimes from its having insufficient nourishment. How is it possible for a weak-growing *Brier* Rose to live upon a lawn formed of poor soil, on which a few spadefuls of mould have been thrown, and perhaps only one spadeful of manure added? And yet there are many who adopt this style of planting. Rose trees so planted, however, soon begin to show signs of sickness, and small blooms are the result; if they should manage to survive one summer they die the following. Roses, in order to flourish, especially standards, must have a good soil enriched with manure in order to make them grow and assume a healthy condition. The soil that the Rose prefers is rarely found on a lawn, and it is for this reason that a large pit or hole must be made as before mentioned. Syrioting the foliage during the summer evenings, mulching the roots with manure in winter, picking off caterpillars in spring, the application of liquid manure, and other general routine, must be attended to if fine Roses be desired; spring and summer pruning must also be attended to. If the above instructions be followed, rosarians, however inexperienced, will be successful. Subjoined is a list of varieties suitable for growing on a lawn; it embraces none of the weak kinds so liable to disease and death; all of them form large-sized heads, and most of them belong to the finest and best of our exhibition varieties, viz:—*Hybrid Perpetuals*—*Abel Grand*, *Baron Hausmann*, *Baroness Rothschild*, *Beauty of Waltham*, *Centifolia rosea*, *Charles Rouillard*, *Charles Lawson*, *Cheshunt Hybrid*, *Dr. Andry*, *Duc de Rohan*, *Duke of Edinburgh*, *Dupuy Jamain*, *Edouard Morren*, *François Michelin*, *Fisher Holmes*, *General Jacqueminot*, *John Hopper*, *La France*, *Lord Clyde*, *Madame Charles Wood*, *Madame Rivers*, *Madame Therese Levet*, *Marie Rady*, *Marquise de Castellane*, *Maurice Bernardin*, *Nardy Frères*, *Jules Margottin*, *Paul Neron*, *Pierre Nottling*, *Princess Louise (Laxton's)*, *Prince Camille de Rohan*, *Roynolds Hole*, *Vicomte Vigier*, *Victor Verdier*. *Moss*—*Baronne de Wassenaer*, *Madame Moreau*. *Tea*—*Madame Falcot*, *Madame Levet*, *Madame Berard*, *Gloire de Dijon*, *Belle Lyonnaise*. *Noisette*—*Bouquet d'Or*. H. TAYLOR.

A Purple-leaved Ivy.—During the last few years I have been cultivating and increasing a beautiful purple-leaved Ivy, which I discovered a few years ago, and which is considered by those who have seen it to be the best of all the Ivies. Imagine a wall all through the dreary winter covered with large leathery leaves of a deep bronze or dark purple colour, and you will be able to form some idea of the appearance of this Ivy. I should be pleased to show it to any one who may feel interested in such matters; all I wish is that the plant was somewhere where it would be more appreciated, for it is growing on an old brick wall ill adapted for showing off its rich colour to advantage; but if grown on a light stone terrace wall or a similar position, or in light-coloured vases, or even as an edging near white or light gravel, it would form one of the most attractive creepers known.—T. WILLIAMS, *Ormskirk*.

Spent Tan.—A few weeks ago a question was asked and answered as to the utility of old or spent tan. Tan thoroughly decomposed, of course, becomes vegetable soil, and makes an excellent top-dressing for borders or beds of flowers, where the soil happens to be stiff or clayey, giving such beds a warm, neat appearance; but the best use to which I have seen it applied was as a mulching for Strawberries—about 4 in. of the material being spread between the rows, as the rains will wash down the particles, leaving 1 in. or more of the coarser material on the top, which instantly becomes dry, on which the fruit when ripe will lie as on a slate. I have seen fresh tan applied extensively to Thorn hedges when newly planted; about 6 in. thick was laid on each side of the Thorns. This acted as a cooling medium in dry summers after planting, and owing to the tan being raw and fresh, not a weed would come through it; the year after the tan was dug in among the soil, and no doubt helped to feed the young trees.—THOS. WILLIAMS, *Ormskirk*.

Early Blooming Primroses.—There is no good ground for the assertion that dark-coloured Primroses flower earlier than light-coloured ones: at least my experience as regards this class of plants does not lead to that conclusion. Just now I have several hundred of large established plants growing in beds in the open unsheltered ground, and all are more or less in bloom, but the white and sulphur-coloured kinds are the latest in flower. They did not begin to blossom earlier than the dark-coloured forms, but it is an undoubted fact that white frosts more readily affect the dark-coloured than the

light-coloured flowers; and it is because of these frosts that the dark-coloured kinds have the least amount of bloom. Early flowering in any Primrose is entirely a matter of cultivation during the previous summer and autumn. Those plants that have the most robust crowns and the strongest foliage will assuredly begin to flower earliest, and thus it may not infrequently happen that the cultivated garden kinds will often bloom much earlier than the wild plants that have to struggle for existence on banks and in nooks in woods where there is neither too much nutriment nor moisture. In spite of the excessive heat and drought of the late summer months of last year all Primrose and Polyanthus plants did exceedingly well, the fine rains of September falling just in time to save the foliage and induce an early growth. The plants are therefore now unusually strong, and are flowering very early; indeed, beds of Primroses, provided we have a few dry sunny days, will be full of flower.—A. D.

Grafting Figs.—Can I overcome the difficulty which I find here in grafting or budding the Fig tree? I have a lot of old native stocks of useless sorts which I am anxious to utilize by grafting with good kinds, but have failed as yet, owing, I imagine, to the abundance of milky sap which exudes from the slightest cut at all seasons of the year. I have been informed that the Fig may be grafted with as much success as other fruits, but although I have been most successful in grafting and budding the native stocks here with almost all the kinds of fruit trees that are cultivated in England, I cannot succeed in grafting the Fig.—R. C. LEE, *Bundrole, Kangra, E.I.* [Grafting the best kinds of Figs on the roots of the common edible sorts would no doubt be successful, since English gardeners in this country find the India-rubber (*Ficus elastica*) to succeed well on common Fig roots as stocks, although they never, so far as we are aware, graft the odible Figs, they being so readily increased by root or stem cuttings or by layering.]

PEAS—THEIR VARIETIES AND CULTIVATION.

The following are extracts from a lecture on this subject delivered the other day by Mr. Pavey before the Lee and Blackheath Horticultural Society. The Pea, said Mr. Pavey, contains more flesh-forming food than is usually found in other vegetables. Its varieties are legion, and it is no easy task to make a selection; nevertheless, I shall endeavour to point out those kinds which in my experience are most worthy of cultivation. In cultivating the Pea, one of the great aims should be to secure a supply of well-filled pods through the greatest number of months, embracing, therefore, early and late varieties. Autumn sowing, provided you can preserve your crop through the winter, will, of necessity, give you a proportionately early gathering. Sowing in pots, to be transplanted, will do the same, and will certainly enable you to place on the table an early dish of Peas; and if quantity be not much regarded, we may practise this mode of cultivation. The Kentish Invicta is one of the best for these purposes, or Dickson's First and Best, or Sangster's No. 1. From the two former I picked, in 1875, on June 10; in 1876, June 24; whilst from the latter not until July 1. A new Pea, Laxton's The Shah, costing as seed 7s. a quarter pint, was ready at the same time as the Kentish Invicta. Growing as we do at least sixty varieties of Peas, all of which are sown on the same day, for the purpose of testing their early, continuous, and late bearing, as well as quality and quantity, the Society will, I trust, accept any statements I make as of no mean value. All Laxton's Peas are good, wanting, however, in flavour, but good croppers. They are high in quantity, and are prolific. His Superlative, which grows 7 ft. high, is one of the best, whilst Fillbasket and Omega are good croppers, but deficient in flavour. Maclean's Little Gem and Blue Peter are both good, the last being the best. In succession to these come Advancer, then Prolific, Best of All, and, finally, Premier. Veitch's Perfection, Napoleon, Eugenie, and Princess Royal, are all to be highly commended. Carter's G. F. Wilson is, in my opinion, entitled to a place in every garden. Among the tall-growing Peas, Champion of England, Fortyfold, Paradise Marrow, Huntingdonian, Competitor, Ne Plus Ultra, and Fairbird's Surprise, are the best; I can commend all these, which are of first quality, and from which selections may be made to supply the main crop as well as for late picking. As a summer vegetable, and one universally prized, it should ever be the aim of the cultivator's special study to secure not merely a good crop of Peas, but also such a variety as will continue the longest in bearing. To be able to place on the table from May to November a good dish of this much esteemed food, the cultivator must sow in the autumn, and carefully preserve his tender Peas by judiciously protecting them during the winter months as well from frost as from slugs and birds; by these resources he may have Peas a week or two earlier than he would have from spring sowing. Spring sowing in pots or, what is better still, sowing on turf, care being taken not to let them be overdrawn or made weakly by coddling, provided a selection be made of the earliest varieties, will ensure an early picking. So treated, the Kentish Invicta or Dickson's First and Best will ripen a week earlier than Sangster's No. 1. There are, however, Marrow Peas of recent introduction—Sutton's Emerald Gem, Laxton's Alpha and The Shah, the last the best, which I recommend far before the early white Peas. For the main crop Maclean's Advancer, Prolific, Best of All, and Premier, or Veitch's Perfection and Carter's G. F. Wilson, growing 3 ft. 6 in. high, cannot be surpassed. If

taller Peas be wanted, we cannot do better than grow the Champion of England, Fortyfold, Paradise Marrow, Huntingdonian, Competitor, or Ne Plus Ultra. The later croppers—Eugenie, Hare's Dwarf Mammoth, and Ne Plus Ultra, ought to be sown the last week in June. The cultivation of the Pea should be on the most liberal scale; well and deeply trenched soil, well manured, either with well-matured stable produce, or, what is equally good, well-rotted garden rubbish. One of the best sites is the Celery trench, provided it be open. All rows should run north and south, which will alone give to both sides the direct rays of the sun. The rows should be as far apart as the Pea will grow in height. These conditions observed, and the variety good, we may fairly expect a good crop of Peas as the result of our labours.

In the discussion which followed Mr. David Hull remarked that his own experience was strongly in favour of Sangster's No. 1 as an early Pea, if grown in pots and afterwards turned out in a properly prepared border. He had grown three varieties in a row—dwarf, higher, and highest—with considerable success. Mr. Abel North said that last year was one of the best Pea years he had ever known since he had been in Blackheath Park, and that was a period of ten years. Laxton's Peas, he had ever found, were generally good. William the First was, in his experience, the best and the earliest Pea; he had picked Peas on the 24th May and as late as November. To get a good dish of Peas a week or ten days earlier than was common was worth any amount of labour. Mr. Kempster was in favour of sowing on turf, and transplanting without disturbing the roots. Dickson's First and Best as an early Pea, and Champion of England, were his favourites. Mr. Tomlinson agreed with the reader of the paper and other speakers as to the value of sowing on turf. When in Norfolk, and also in Derby, he had gathered on the 8th June. The Early Emperor he regarded as the best, and a good second was Dickson's Favourite. Mr. W. North said his rule was never to sow until February, and yet he gathered almost as early as his neighbours, and often as late as November. Dr. Carr urged the value of obtaining seeds from the south of Europe, knowing, from experience, that such Peas will ripen their fruit earlier by many days than the same variety grown in England or Holland; if, therefore, it be of importance to be earlier in the field, one of the readiest means is to purchase seed which has been grown in the south of France.

OBITUARY.

We have to announce with deep regret the death of Mr. Harrison, of the North of England Rose Nurseries, Catterick Bridge, Yorkshire, an event which took place suddenly on the 4th inst. Mr. Harrison was one of the most successful of north country Rose growers.

NOTES AND QUESTIONS—VARIOUS.

Glazing without Laps.—I am glazing a Peach-house with a steep incline without laps. The glass is cut fairly even, but still there is a drip. Can any of your readers suggest any thing of a transparent character to run in between the panes so as to exclude wet? I am trying as an experiment a plan of slipping the panes of glass up in grooves and wedging them in with fine india-rubber tubing. Will this be likely to succeed as regards the durability of the tubing?—G. C.

Salt as a Manure.—For light, sandy soils salt is one of the most economical and effective of all artificial manures. The best season in which to apply it is during winter, over vacant ground that has been previously dug or trenched. It should be sprinkled on the surface at the rate of 1 lb. to 1½ lb. per square yard, and left for the rains to wash it into the soil. Previous to seeding or cropping, the ground should be lightly pointed over, as the salt has a tendency to cause it to bind together.—W. H.

Protecting Peas.—"N. F." (see p. 99) wishes to know how his early Peas sown in November may be best protected should cold cutting winds follow the present mild weather. I have some in the same stage of forwardness as those of "N. F." and have put a ridge of ashes on each side of the rows, high enough to shelter the Peas at present; but should severe frost or cold, cutting winds set in, some small branches of Spruce Fir will be put in the side of the rows to afford better protection. If sparrows be troublesome in nipping the foliage, which they often do in February and March, a little soot dusted over the rows now and then will help to keep them off.—WILLIAM TILLEY.

Anemones in Flower in Hampshire.—Different varieties of Anemone (*A. coronaria*) are flowering much earlier with me this year at Lymington than I have ever known them to do at Cannes, whence the tubers were brought two years ago. They occupy a very high and exposed spot in the kitchen garden, and notwithstanding the severe storms of wind and rain to which they have been subjected, they have been quite gay ever since the early part of November, though not quite so bright in colour as they would have been had we had more sunshine.—M. G. S.

Soiling Mushroom-beds.—The surface of Mushroom-beds can scarcely be made too firm, as the Mushrooms in that case form directly on the surface, and are easily gathered without disturbing the beds. In loose soil, on the contrary, the Mushrooms will frequently form on the manure, as mentioned by "W. D. C." (see p. 77), and will force the soil up in their progress through it. We have at present many under such conditions that have come up on last season's Melon-beds, although the house has been kept quite cold, and the beds have been covered with coal-ashes, on which *Calceolarias* and similar cool-house subjects have been set.—J. GROOM.

Centennial Exhibition Awards.—Mr. Bull, King's Road, Chelsea, has just received official notice from the Director-General of the Philadelphia Exhibition, that he has been awarded a medal for pictorial representations of new plants.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

GROWING SOME RARE HARDY PLANTS.

IN an underground tank filled with leaf-soil and peat, I have had some of the grandest plants of *Cypripedium spectabile* I ever saw; one plant had thirty spikes nearly 2½ ft. high, all bearing two flowers on a stem; almost side by side are the new Californian Tulips, growing away right merrily. I put a quantity of rich leaf-soil below and then a good layer of cinders; *Calochorti*, *Cyclobothras*, *Brodiaeas*, *Tulbagias*, *Iris tuberosa*, and *I. persica*, were then planted in a layer of sand above the cinders. All of these have done well. *Cyclobothra pulchella* (the Golden Star Tulip) was in bloom nearly the whole of the early summer, and planted in this manner it will be one of the finest bulbs for the herbaceous border. I am eagerly looking forward to seeing my *Calochorti* this summer, as at present they seem to be doing rather too well. Mr. Ware succeeds with them on a small, raised rockery, and I fancy we shall find them quite hardy when better understood. I can thoroughly recommend for all warm soils the Orange *Alstroemeria* (*A. aurea*), which grows and seeds freely here; it is difficult to transplant, and should be obtained well established in pots, and planted with a layer of coarse ashes immediately below the tubers to keep them dry during the winter. Another tuberous rooted plant requiring similar culture is the variegated *Commelina cœlestis*; its leaves are beautifully striped like those of the variegated Lily of the Valley, and the blue flowers form a delightful combination. I think some Cocoa-nut fibre should be put over the roots in winter; indeed, the value of this material for protective purposes is not nearly well enough known. It forms a capital component of soil for sowing seeds of all sorts, keeping them moist and the soil thoroughly porous. I tried *Hedychium Gardnerianum* out-of-doors this summer according to Mr. Harpur Crewe's advice, but though the roots increased rapidly the leaf-growth was not very encouraging, and I do not intend to try it again. I have a plant of the Scarborough Lily (*Vallota purpurea*) doing well out-of-doors in a warm corner, well protected with Cocoa-nut fibre, but I find the *Belladonna* Lilies send up their leaves too early, so that they get cut by spring frosts. I saw at Oxford a grand plant in the open border of *Pancreatum illyricum*; *P. maritimum* has not proved hardy there, but the first-named is evidently a perfectly hardy border plant, and should be planted extensively. *Crinum capense* is of course quite hardy here. Colonel Trevor Clarke speaks of *Crinum ornatum*. I saw at Glasnevin an enormous spike of flowers of *Crinum ornatum grandiflorum*. The climate of Glasnevin is very different from that of the Midland Counties. Has *Amaryllis Ackermanni pulcherrima* flowered with Mr. Harpur Crewe? I have it, but have not yet tried it in the open ground. The new Golden Chickweed, grown in moist soil, makes one of the finest carpet plants I ever saw. This would be a useful plant for carpeting large beds of *Colchicum autumnale* or *C. speciosum*. The little Purple-leaved *Oxalis* (*O. corniculata*) is another plant which would form an exquisite contrast with the lovely autumnal *Crocuses* or *Colchicum album*. Talking about contrasts, I am trying 100 plants of *Lilium longiflorum* in a bed of *Clematis Jackmanni*; they would be even more lovely among different coloured *Petunias*. I have this Lily growing among Monthly Roses, just peering through the pegged-down bushes, and peeping above the clusters of its blushing inamorata.

FRANK MILES.

PLANTING OUT FORCED BULBS.

WHAT to do with Dutch and other bulbs, after they have flowered in pots, appears with many to be a difficult question. My own way of dealing with them is to plant them out where they can be left undisturbed. But the question may arise, where is such a spot to be found; for beds and the majority of borders in which bedding plants are grown require deep

winter cultivation. In spring gardening bulbs, form an important feature, but they must either be imported or selected ones of home growth, as, on account of their having often to be lifted when in full growth, and laid in by the heels, as it is called, to ripen in out-of-the-way places, they diminish rather than increase in size and strength. It is, however, quite another matter when they can have a permanent position, in which they are allowed to perfect their foliage and ripen their bulbs undisturbed in the ground. Taking them up and storing them is an unnatural system—a trying ordeal through which they may live, but that is rather a proof of their strong vitality than that they are in any way benefited by the exposure to which they are thus subjected. Since herbaceous and mixed borders proper have, however, once more become a reality, positions for bulbs will be found in them; indeed, we have annually planted the remnant of our forced bulbs of all kinds in such borders, and certainly they are as capable of taking care of themselves as any plants with which I am acquainted, for they not only grow and flower freely, but increase into large masses, a condition in which they have a far better effect than if planted in rows with geometrical precision. Having stocked all such available positions and the margins of permanent beds devoted to *Rhododendrons* and similar plants, we last year planted all our surplus bulbs on the edges of our Rose beds and banks, and they are now showing an abundance of sturdy spikes of bloom, which materially add to the appearance of the beds without the least probability of detracting from the success of the Roses as by the time their leaves get thick, the bulbs will be going to rest under their shade, while the same cultivation suits both, merely keeping the soil free from weeds and adding a good top-dressing of rotten manure and rich mould, for neither likes the spade among their roots. It has been remarked that bulbs are difficult to suit as regards soil, but if it be rendered friable enough by cultivation for ordinary border plants, there need be no fear on this score. Of course if the object be to get fine bulbs for any particular purpose, rich soil and plenty of room for each bulb will yield proportionally rapid and satisfactory results; but for affording a brilliant display in the open air, plant well at first, and they will need but slight attention afterwards.

JAMES GROOM.

Good Climbing and other Roses.—The reddest and richest of all my Roses is Reynolds Hole—a Rose worthy of its namesake. The new Tea Rose, Letty Coles, seemed to me, at the Westminster Aquarium, to be the loveliest Tea Rose I ever saw, and the largest; it is flesh-coloured, richly marked with deep pink, and entirely distinct: Mr. Keyacs, of Salisbury, is sending it out. The old Tea Rose, *Abricoté*, is another plant for our borders; it is perfectly hardy, and never ceases blooming. Rose Princess Louise Victoria is the best pink climber I know of—climbing well and bearing good flowers in colour something like those of *Eugenie Verdier*. Climbing Jules Margottin I do not think much of, but climbing Victor Verdier is one of the best Roses in my garden, deliciously sweet, and blooming profusely in dense clusters.—F. MILES, *Binham*.

Grafting Figs (see p. 120).—Various modes of grafting and inarching Figs may be performed with safety, but, as a rule, the one which I practise is that known as dovetail grafting, a plan by which fruit can be gathered from the scion during the year in which it is grafted. Now is a good time to perform the operation, provided the trees have been some time started and are commencing to form leaves. The stock may be of one or more years' growth, but I prefer both it and the scion being of one thickness. I select a clean, straight place on the shoot on which to insert the scion, which should be about 2 in. in length; the scion should have a bud in the middle, its ends should be clean and cut straight across, and it should be split up through the pith; I then place the scion on the stock, and mark at each end its exact size, removing the wood to a depth corresponding with that of the scion, and tying neatly and firmly with a piece of Reed Grass; I then make a deep incision immediately before the bud, which soon begins to grow. My practice, I ought to say, applies to Figs under glass. Some shoots here from eyes put in last year as described, are upwards of 5 ft. in length, and nearly ¾ in. in thickness.—J. HUNTER, *Lambton Castle*.

Poinsettia pulcherrima major.—I have not seen this variety in flower. Is it merely a stronger grower, or are the bracts larger, different, or higher-coloured than those of the more common type? I also wonder that the so-called *P. pulcherrima alba* is not more grown than it is.—D. T. F.

NOTES OF THE WEEK.

EDELWEISS IN OXFORDSHIRE.—Mr. Vair's very interesting notes about this in THE GARDEN (see p. 105) remind me that I saw this plant growing vigorously as a border-flower in Mr. Boulton's collection at Great Tew Park, in Oxfordshire. Growing freely in rich borders, however, the plant does not look quite so pretty as on the mountains.—V.

PAPER-WHITE NARCISSUS.—Large clumps of this snow-white-flowered Narcissus, growing close to a wall in the Fulham Nurseries, are now throwing up scores of vigorous flower-spikes, crowned with from ten to twelve buds and expanded blossoms, each of the latter being as large as a florin. The beauty of these open-air flowers is greatly superior to that of the white kinds forced in pots which one usually sees in the market.—W.

ANEMONE PULGENS IN JANUARY AND FEBRUARY.—This early and brilliant flower has been in bloom in quantity in M. Henri Vilmorin's garden at Verrières, near Paris, for the past five weeks. It is impossible to over-estimate the value of this plant as an early spring, and even a winter flower in mild seasons. I have lately had the opportunity of seeing in Paris some vases solely filled with the cut flowers of this Anemone, and the effect of the flowers by artificial light was almost as fine as it is in the open ground in the sunlight.—V.

MOLINIA CERULEA VARIEGATA.—This British plant in its variegated form is not infrequently used as an edging for flower beds; this spring, however, Mr. Green, of the Holmesdale Nurseries, Reigate, has been very successful in forcing it in pots; and, treated in this way, it forms tufts of pale green, yellow-striped foliage, well suited for association with Cyclamens, purple and blue Hyacinths, and other spring flowers.—B.

DAPHNE INDICA RUBRA OUT-OF-DOORS.—A specimen of this well-known, sweet-scented, greenhouse shrub growing in an outside border at the end of one of the plant-houses in Osborn's nursery, is now, as it has been all through the winter, producing trusses of rosy-white blossoms in abundance. Might not this Daphne, therefore, be advantageously planted in warm, sheltered positions in the Southern Counties, where it would doubtless succeed even better than at Fulham?—C.

CYCLAMEN PERSICUM OUT-OF-DOORS.—The Hon. and Rev. J. T. Boscawen informs us that the Persian Cyclamen succeeds well out-of-doors in his garden at Lamorran, in Cornwall, planted under a specimen of *Pinus insignis*, the falling leaves of which afford protection to the corns alike from frosts and droughts. It is also now flowering in the open air in Sir W. Marriot's garden, at Blandford, in Dorset. It would, therefore, seem to deserve a place on sheltered rockwork, especially in our southern counties, or in favourable localities elsewhere near the coast.—B.

CLIVE HOUSE SEEDLING GRAPE.—This Grape was exhibited at South Kensington in December last, and received a first-class certificate as a large-berried late Black Grape of good quality. At the meeting of the Royal Horticultural Society's Fruit Committee, held there on the 14th inst., the name was formally cancelled, owing to some misrepresentation having been made by the exhibitor.

THE WHITE-FLOWERED JAPAN QUINCE.—Flowering specimens of this valuable autumn, winter, and spring-flowering shrub were exhibited before the Royal Horticultural Society, on Wednesday last, by Messrs. Veitch & Son, and were awarded a first-class certificate. The flowers and buds of this variety are pure white, without a trace of the flesh-colour or pink suffusion which is to be found in all other so-called white varieties of this plant. When sufficiently plentiful to be planted in shrubbery borders, bushes of it will form a striking contrast with those of the crimson-flowered kinds.—F.

WHITE CALVILLE APPLE.—A bush specimen of this well-known French culinary Apple, growing in a pot, was exhibited at South Kensington on Wednesday last by Mr. Stevens, of Trentham. It bore about a dozen large and well-ripened fruits, and a cultural commendation was awarded it. Similar specimens of this variety, grown in an orchard-house, are used at Trentham for decorative purposes.—B.

CYDONIA JAPONICA AS A STANDARD.—A large plant of this attractive spring-flowering shrub, grown as a standard in a villa garden at Tooting, is just now a mass of rich scarlet blossoms. It has a clean stem of 3 ft. or 4 ft. in height, surmounted by a well-shaped head from 5 ft. to 6 ft. in diameter. This *Cydonia*, grown in this form, potted in the autumn, and brought into flower a month or so earlier than usual, would doubtless be found very useful in the conservatory. Plants of it in this shape could easily be secured by grafting the

Cydonia on stems of the common White Hawthorn, and when well established, potting them and placing them in a cool house as soon as cold weather sets in. Thus treated, their bright scarlet blossoms would show themselves off to advantage, and would probably give more satisfaction than more troublesome and costly subjects.—S.

CROCUS-GROWING FOR MARKET.—The Crocus beds in Mr. Yeldam's grounds at Hammersmith are now very effective, upwards of $\frac{1}{2}$ acre being occupied by them. The common yellow, white, and blue are the kinds grown, and being intermingled they have a fine appearance. Being grown for sale in a flowering state, they are taken up in small clumps, their roots tied in Moss, and packed in boxes. Many thousands of them are disposed of in Covent Garden, but the majority of them are sold by auction.

APPLES FROM A SUSSEX GARDEN.—One the most interesting features of the Exhibition held at South Kensington the other day was a collection of Apples, sent by Mr. W. E. Hubbard, of Leonardlee, near Horsham. Not only were the individual fruits large of their respective kinds, and remarkably handsome in point of colour, but in nearly all cases they appeared as plump, and as fresh as if recently gathered from the tree. These Apples were far more beautiful than any we have seen imported from the Continent.—F.

CAMELLIAS, AZALEAS, AND EPACRISSES.—Of these many hundreds are now in bloom in Messrs. Lee's conservatory at Hammersmith. Among Epacrisse *E. Hyacinthiflora carminata* and *E. rubra superba* are the most effective, and amongst white Azaleas one of the best is Mademoiselle Maria Lefebvre, many of the blossoms of which measure from $\frac{1}{2}$ in. to 5 in. in diameter. This is probably the largest white kind of Azalea in cultivation.—S.

CLEMATIS INDIVISA LOBATA.—This is without doubt the most useful greenhouse climber that we possess for furnishing a quantity of pure white blossoms during the winter and spring months. A large plant of it, growing in a cool-house in Messrs. Osborn's Nursery at Fulham, is now thickly furnished with long pendent wiry shoots, literally covered with bloom, a condition in which it has been for many weeks past. In addition, too, to their attractiveness on the plant, the flowers are invaluable for cutting.—S.

CAMELLIAS FOR THE LONDON MARKET.—Some idea of the extent to which Camellias are grown for sale near London may be gleaned from the fact, that one grower alone at Hammersmith, cut on one morning last week 325 dozen blooms, all of which were disposed of in the London florists' shops.

EURYCLIS AUSTRALASICA.—Flowering plants of this old-fashioned species were exhibited by Messrs. Veitch & Sons at South Kensington on Wednesday last, and excited considerable attention. It is a bulbous plant, bearing dense clusters of pure white Ranunculus-like flowers. Its leaves are like those of a strong-growing *Funkia*, being ovate-cordate, and of a bright green colour. The specimens shown were flowering very profusely, and the plant deserves notice as one well adapted for supplying cut flowers as well as for general decorative purposes. It was figured by the late Dean Herbert in his "Amaryllidaceae" some thirty years ago, and also in the "Botanical Register," vol. ix., t. 715.—B.

EARLY FLOWERS AND THE RAIN.—It is astonishing how well Violets have flowered this winter, and how thoroughly pure and sweet they are after weeks and months of rain; the water seems to run off from such tall, single Violets as the *Czar* and *Victoria Regina* without hardly wetting them. Snowdrops, too, seem to enjoy the continuous wet weather, and no amount of it tarnishes their purity. The large Crimean and old single Snowdrop are especially fine this year, and look all the more pearly-white from the incessant downpour. The Early Forget-me-Not (*Myosotis dissitiflora*), on the contrary, does not seem to like the constant wet. The larger patches of it seem inclined to die off, and the smaller ones are neither so healthy nor so early as usual. Early Primroses also seem to dislike the incessant rain, and many of their flowers here are partially disfigured and decomposed with the wet.—D. T. FISU, *Hardwicke*.

A FIFTY-GUINEA ROSE PRIZE.—At the last meeting of the Committee of the National Rose Society it was announced that Mr. Cranston, of Hereford, had offered a challenge cup of the value of fifty guineas to be competed for by amateurs, the cup to be won in three years: thus, if Mr. A. wins it in 1877 and Mr. B. in 1878, then only A and B are to compete for it in 1879.

LILY BULBS.—Our descriptions and figures of some of the more remarkable Lily bulbs will be completed in our next issue. The space occupied during the present week by such a number of engravings, necessitates our withholding several other valuable communications.

THE FLOWER GARDEN.

A HIMALAYAN PRIMROSE.

(PRIMULA INVOLUCRATA MUNROI).

THIS very distinct and beautiful Primrose appears to have been first gathered by Captain Munro, on the Himalaya Mountains, at an altitude of 11,500 ft., where it was found growing in company with the lovely blue *Cyananthus lobatus*. Its tufted, dark-

Primula involucrata Munroi.

green leaves, which are crenated, are borne on long, winged petioles, and its white, lilac-tinted flowers, each about the size of a sixpence, are borne three to five together on a slender stem from 6 in. to 8 in. in height. *P. involucrata* Munroi differs from the type in being larger in all its parts and more

Blooms of Primula involucrata Munroi (natural size).

vigorous in its growth, but both forms well deserve careful culture. They are perfectly hardy, and succeed well in any well-drained soil, but best among nodules of sandstone, and rich vegetable earth in sheltered positions. The annexed sketches of this delicate Primrose were made at South Kensington about a year ago, when Messrs. W. Cutbush & Sons, of Highgate, exhibited a pan of it in excellent condition, its graceful trusses of delicately fragrant lilac or white

blossoms being freely produced from among clusters of healthy leaves, which overran the surface of the pan; indeed, the plant was effective enough to be very generally noticed and admired, although surrounded by masses of more highly-coloured and more showy decorative plants. This Primrose produces seeds in fair quantity, and these grow readily if sown as soon as they are ripe in a warm greenhouse temperature; but it is essential that the soil in which the seeds are sown is never allowed to become dry, as that at once kills the young seedling plants; to prevent such an occurrence, boxes are preferable to pans, especially to new ones, since the latter absorb moisture quickly from the soil and starve the young plants to death almost before they peep up through the mould; hence it is that we often see seedling Primroses and other delicate plants come up in the centre of the pan, while the soil near the sides is unproductive. B.

CHRYSANTHEMUM CULTURE IN RUTLANDSHIRE.

Now that Chrysanthemums are getting more and more every year into favour, perhaps a few observations, the result of four years' experience, at least as far as their cultivation in pots is concerned, may be welcome to some who are only just beginning to take them in hand. To begin at the beginning; let us suppose that the would-be grower has been captivated by some good display, such as that which may yearly be seen in the Temple Gardens and elsewhere, and that he has noted down the names of the sorts which pleased him most, he naturally asks how he can grow plants equally fine, and where he can obtain cuttings. In the first place, be it stated that, in order to grow Chrysanthemums in perfection, they must be raised from cuttings every year, for plants obtained by dividing the old stools will not produce such fine blooms as plants raised annually from cuttings. It would therefore seem obvious that the beginner has an equally good chance with the grower who could procure his cuttings from his own plants as early as he wished; but that is not the case, for it is almost impossible to obtain fine stocky-rooted suckers or cuttings very early in the season, unless one has old plants from which to obtain them. I would therefore recommend the purchase of rooted cuttings in the spring, which any of the leading nurserymen can supply, and which I believe are usually sent out early in April. These, if well attended to, will make good plants in autumn, and will generally supply a goodly stock of early cuttings. This is a much safer plan than trusting to unrooted cuttings in the winter sent by post. At all events I recommend, in the case of the large-flowering varieties, that the cuttings should be taken as early as possible, say about the middle or not later than the end of November. Do not take any cuttings of shoots that may be on the old stems, but choose short, sturdy suckers with a portion of root attached to them if possible, and pot each separately in a small 60-sized pot in fibrous loam, mixed with a little leaf-mould if the loam be heavy. The soil should not be too wet. Place the young plants on a bed of coal-ashes under a cold frame close to the glass, and keep them pretty close till they are established, after which they cannot have too much air, and only need protection from severe frost, heavy rains, or cold, cutting winds. It is a mistake to winter them in a greenhouse, as they are never so healthy, and are apt to become tender and weakly even with abundance of air, and to suffer if the atmosphere of the house be kept too dry. Supply them continually with water, and as the spring advances, watch their roots carefully and shift the plants into larger pots before they become pot-bound. They should not, however, receive their first shift until the roots have well penetrated the drainage, as harm might result before spring-growth had well begun. I prefer only to give a small shift for the first one, say, into 4-in. pots, but afterwards they may go into 7-in. or 8-in. pots, and from these into their blooming pots without danger. I use no leaf-mould in the compost after they have left the cutting-pot, but simply fibrous loam (which may be used quite freshly cut), and any well-rotted manure in moderation at first, but later on in larger quantities, according to the condition of the loam. The finest stimulant, as mentioned in a former number of THE GARDEN, is manure collected fresh from the stable and stored in a sufficient quantity to heat a little, when it should be worked through a fine

sieve until thoroughly broken up. If very large blooms be desired I do not stop the plants at all; but I have grown plants in 12-inch pots of some of the large-flowering sorts like *Empress of India*, with a dozen or more stems and as many blooms, each measuring quite 6 in. in diameter. Plants of the above-named variety would in that case be about 5 ft. high when in bloom, but would, of course, attain a greater height if kept unstopped. If considered desirable to stop the plants, with a view to making bushy specimens or increasing the number of blooms, this should be done when they are about 6 in. high, taking care to pinch out the points. It is a bad plan to let them grow longer than is intended, and then to top them back several inches.

Lyddington, Uppingham.

B. H. MARGETTS.

HYBRID PRIMROSES.

PRIMROSES are, perhaps, the easiest flowers to hybridize and the best for beginners in that delightful occupation; of course the piu-eyed ones are the easiest to cross; indeed, I have never crossed any of the thrum-eyed kinds. I hate the nonsense about certain flowers being florist's flowers, and any not coming up to that definition being regarded as almost worthless; if we all went by the florist's rules we should not have the grand, highly-coloured Polyanthuses raised by Mr. Dean and Mr. Ware. To raise one's own strain of Primroses, begin with the mauve variety and the deep crimson known as *Primula auriculæflora*, and the most distinct of Mr. Dean's named seedlings. I shall never forget seeing, for the first time, Mr. Dean's Primroses at Bedford, near Feltham station. It is an easy journey from London, and those who think they have fine seedlings of their own would be astonished at the rich colours of the Bedford varieties. In crossing Primroses, the influence of the male pollen is very striking. In such plants as I have hybridized I generally find that the female influences the seedlings most; but here the case is reversed. I crossed a white Primrose with my finest coloured varieties, hoping thereby to raise pale but pure tones of pink, lilac, and so forth. I had only one white out of forty seedlings; all the rest are even richer and purer in colour than their male parents. The seed was sown in July in deep saucers, full of turf and Cocoa-nut fibre well mixed; they bloomed the following spring, and were then put on the shady side of a fence; the crowns grew all the summer and began to throw up flowers at the end of October. They are now in full bloom, and I have just taken them into the greenhouse; they are certainly more beautiful than Chinese Primulas, and are much easier to manage. The great secret as regards getting hybrid Polyanthuses and Primroses to bloom during the winter is to place fresh soil round the crowns as soon as the old leaves are dead, and to keep them moist during the dog days. I agree with Mr. Dean in thinking the mauve Primrose more than a variety of the common yellow Primrose, but I differ from him respecting the sowing of seed; he thinks it should be kept a year, the seed thereby coming up more regularly: I hold, on the contrary, that it should be sown as soon as it is ripe and kept under glass. I find that in this way the seed germinates with greater certainty and better than if kept a year; moreover, it is a manifest advantage to obtain flowering plants in less than a year from the time when the seed is gathered. Those who know the excitement attending the raising hybrid seedlings will appreciate this. I have, side by side, two boxes of Primrose seed sown on the same day—one full of fine young seedlings from seed sown as soon as it was ripe, the other of Mr. Dean's seed, with hardly any leaves yet showing. I have no doubt whatever that *Primula cortusoides amoena* will seed if crossed with Polyanthus pollen. What does Colonel Trevor Clarke mean by saying that there is no such thing as a white Primrose, and that all white Primroses are Polyanthuses? I understood him to this effect, but I have never had the opportunity of asking him about it afterwards. I have found white Primroses growing wild among the yellow ones. The mauve variety is one of the grandest plants for an outside window box with which I am acquainted; if grown in the shade in the summer it will flower freely during the winter and early spring.

Bingham.

FRANK MILES.

CROCUS EDGINGS.

My line of permanently-planted Crocuses is just now in full bloom in my garden, and when the sun shines the flowers open their petals to the utmost, and form a charming floral rainbow, for the line is crescent-shaped, and it serves as a margin to a mixed border in which *Roses* and other plants play an important part during summer. The bulbs were planted four years ago; a trench was dug out 1 ft. in depth next the Grass; at the bottom were placed 4 in. of fibry turf, and in this 2 in. of leaf-mould. The bulbs were planted in October, pressed firmly into the leaf-soil, and then covered with sand; the soil was then replaced, and the whole trodden firmly down. The first year I had some fine blooms, and the second and succeeding years a profusion of them. This is the way in which Crocuses should be treated, for they bloom earlier, freer, and much finer than when planted each autumn and lifted in the spring. In planting my row of bulbs I kept in view a continuation of flowers and a proper blending of colours. To insure blossoms in October I made use of a few bulbs of the autumn-blooming *Crocus speciosus*, with here and there a bulb or two of *Celchicum autumnale* and *Crocus Imperati*. The rich blue-purple of *C. speciosus* may be seen in October, and is succeeded by the *Colchicum*. In February *C. Imperati* appears, and is quickly followed by *C. biflorus*, white pencilled with black, and the golden *C. reticulatus*. I had nothing beyond these two till the warm sunny days of last week set in, and then there sprung up as if by magic the blossoms of some of the finer varieties of *Crocus vernus*, such as the Large Yellow, Sir Walter Scott, delicately pencilled with violet stripes; *Pride of Albion*, a remarkably fine, heavy-striped variety; and *Princess of Wales*, also a beautiful pale striped variety. Up to this time none of the purple kinds, such as *Ne Plus Ultra*, *David Rizzio*, and Sir John Franklin, have flowered, but it will not be very long before they do; and with them I shall have, for the sake of the blue tints which they supply, *Scilla bifolia* and *S. sibirica*. The presence of a margin of Crocuses never interferes with the summer occupants of the bed, and on all occasions when it is dug the Crocuses are left undisturbed. Early in autumn the soil is carefully removed to the depth of 2 in. or 3 in., and some spent manure sufficiently dry to be pulverised is placed in the trench to act as a top-dressing, and the removed soil is replaced. During summer two or three good soakings of liquid manure are given, with a good result. It is sometimes urged against the use of Crocuses in this way that the foliage has a littery appearance in spring, but the grievance must be regarded as a very small one. In the case of all permanently planted lines of Crocuses the bulbs should be lifted and replanted every six years or so. This is necessary in order that the soil in which they are growing may be renovated, and also for the purpose of keeping the bulbs low down in the soil.

D.

ANTIRRHINUM TOM THUMB.

LAST spring I had a collection of Tom Thumb Antirrhinums from Messrs. Veitch in eight different colours, and very dwarf, distinct, and beautiful they were. Some of the flowers were striped, others bleached in various forms and colours; but all were good, and, as a rule, the distinct colours were fairly true, which is more than can be said of all packets of seeds marked distinct. Everybody who saw the blooms admired them, and towards the autumn, when nearly all other outdoor plants were shorn of their beauty, the Antirrhinums seemed to improve, and continued flowering till the end of November. Seeds, sown during the next fortnight or three weeks in a gentle heat, when large enough pricked off into boxes, brought on for a time in a close, cool frame, afterwards hardened off and planted out in May, will come into bloom by the end of June, and continue flowering till late in autumn. Here and there one may be found that will grow rather taller than the rest, but these can easily be picked out when the plants are taken from the boxes, as by that time they will have developed their true character. If planted about 6 in. apart, an effective bed will be the result, and a new and pleasing feature may be given to it by planting seedling plants of the *Acacia lepantha* from 2 ft. to 3 ft. apart amongst the Antirrhinums; and if a bread band or verge of the variegated *Mesembryanthemum* be added, it will impart a neat finish to the whole. With beds of this character there is not much labour or care required, and they continue to improve till long after the usual bedding plants are fit for removal. The *Acacia* is very elegant, and takes off the flatness of the dwarfier plants, and the light and shade that seem to play amongst its light, feathery branches, bring out and improve the effect of the Antirrhinums. If the *Acacias* be sown now, and brought on in a moderate heat, they will be large enough to plant out by the usual time, but no time should be lost. The Antirrhinums, being hardy plants, may of course be sown in the open air, but if so, they will not flower till late in the year, and will consequently not be so useful this season.

E. HODDAY.

EFFECT OF THE WINTER ON VEGETATION.*

HITHERTO the winter has been a somewhat remarkable one, being characterized by wind and rain in excess, with comparatively little snow and frost, particularly about Edinburgh. The first snowfall, and perhaps the heaviest, was on November 8 and 9, and it did a vast amount of injury at the time by breaking down branches and damaging the bark of many deciduous and evergreen trees throughout Scotland, such as Oaks, Beeches, Elms, Silver Firs, and Spruces. This, and also subsequent falls, rapidly disappeared, although snow up to this time in this locality has been less than usual; rain has, however, fallen in greater abundance during the last five months than it has been known to do in this district during the same period for many years. So much has this been the case that all low and level grounds are completely saturated with water, and therefore very much against the flowering of many of the hardy spring bulbs. Snowdrops, for instance, at this particular time (Jan. 31) used to be abundantly in bloom, not only on elevated grounds, but all over the level garden lawns; now they are only to be seen partially in flower on raised and sloping banks where the ground is somewhat dry, while those on flat lawns and in low, damp situations, are scarcely appearing above the surface of the soil. This dampness may also account for the backwardness apparent in the flowers of the Crimean Snowdrop (*Galanthus plicatus*), *Leucojum vernum*, *Crocus susianus*, and even the varieties of *Crocus vernus*, all of which were in flower during the month of January last year, when the weather was colder. I am not prepared to say how long it is since we had such an amount of moisture during any one winter, but this I do know, that for the last fifty years we have never been troubled with water in our garden stockholes till last month, necessitating pits to be sunk in them and otherwise much labour in getting it out. What effect this excess of moisture will ultimately have on the roots of many shrubby and herbaceous plants growing near the surface it is difficult to say.

Owing to the mildness of the weather, many of our autumn plants have continued more or less in flower throughout the winter—kiuds in all probability which would not have been in bloom during an ordinary severe one. Among plants that have been in flower, may be named Primroses, Polyanthuses, *Gentiana acaulis*, *Veronica rupestris*, *Lithospermum fruticosum*, *Potentilla alba*, *Iberis*, *Aubrietia*, Wallflowers, &c.; while the various species of Christmas Rose have been remarkably fine, as well as the Winter Heliotrope (*Tussilago fragrans*), *Sternbergia lutea*, and *Crocus Imperati*, both the latter growing on high parts of the rock garden; *Erica carnea alba*, *Jasminum nudiflorum*, *Garrya elliptica*, and the Laurustians, have also been finely in blossom. The flowers of the common Hazel have been particularly abundant throughout the month, and if no frost should occur, a full crop of Hazel Nuts may be confidently looked for in autumn.

From the selected list of forty-two plants whose flowering has been annually recorded during the last twenty-seven years, four species only flowered during January; while eleven species of this number were noted during the same month last year.

	1877.	1876.
<i>Corylus Avellana</i>	January 1 —	January 14
<i>Tussilago fragrans</i>	" 3 —	" 12
<i>Hepatica triloba</i>	" 8 —	" 12
<i>Galanthus nivalis</i>	" 15 —	" 16

Besides herbaceous plants there are also several other shrubby species which are usually noted as being in bloom in the open air at this particular time, but which are still considerably behind. Of these may be mentioned the *Daphne Mezereum*, *Rhododendron atrovirens*, *R. Nobleanum*, and *Cornus Mas.*, but whether this arises from the sunless, wet autumn, or the want of the necessary amount of frost to mature them for early blooming, it is difficult to say, probably both combined.

To the meteorological tables which I have for the last twenty-two years prepared, showing the amount of frost during each month from October till April inclusive, I have to add the following observations:—In October 1876 we did not record a single degree of frost, notwithstanding that 352° were registered during the united October months for the last

twenty-two years. The lowest markings were in 1856, 1857, and 1862, when 3° only were indicated during each October month, while the highest was in 1859, when 56° of frost were registered. The lowest markings during the month of October, 1876, were on the 2nd, 23rd, 25th, 26th, 27th, and 31st, when 37°, 37°, 36°, 37°, 33°, and 35° were indicated, while the highest morning temperatures were on the 7th, 8th, 9th, 17th, 18th, and 19th, indicating respectively 55°, 53°, 50°, 50°, and 50°. During the month of November, 1876, the thermometer was thirteen times at or below freezing point, indicating collectively 82°, being 2° more than was noticed the previous year; the lowest markings being on the mornings of the 7th, 8th, 10th, 11th, 29th, and 30th, indicating 266°, 26°, 20°, 22°, 23°, and 25°, while the highest morning temperatures were on the 3rd, 4th, 5th, 17th, 18th, and 19th, indicating 45°, 45°, 46°, 45°, 42°, and 43°. During the month of December, 1876, the thermometer was twelve times at or below the freezing point, indicating collectively 43°, while the corresponding month last year indicated 81°; the lowest temperature being on the mornings of the 1st, 13th, 23rd, 24th, 26th, and 27th, indicating 29°, 25°, 24°, 26°, 27°, and 27°, while the highest morning readings were on the 2nd, 5th, 6th, 7th, 10th, and 11th, indicating respectively 42°, 43°, 44°, 45°, 43°, and 43°. In January last the thermometer was sixteen times at or below the freezing point, indicating collectively 73°, while 103° were registered during the same month last year. The lowest markings during January were on the mornings of the 2nd, 3rd, 12th, 15th, 22nd, and 23rd, indicating 20°, 18°, 23°, 27°, 26°, and 28°, while the highest morning temperatures were on the 8th, 9th, 11th, 19th, 20th, and 28th, indicating 40°, 37°, 37°, 38°, 39°, and 37°.

Rocky Mountain Columbine (*Aquilegia cœrulea*).—The plant, my mother's drawing of which was so well figured in THE GARDEN (see page 90), I grew from seed supplied by Mr. Thompson, of Ipswich, to whom we are indebted for introducing this lovely 'gem into English gardens. I would as soon leave a noble Hybrid Lily to the world with the certainty of its giving unending delight to millions of people in future ages as be revered for a Raphael, or sung for ever as Handel: so the man who introduced this Columbine may end his life happily. Its culture is not difficult. Sow the seed directly it is ripe: the seedlings come up quickly and with certainty. Prick them out into slate-bottomed boxes as soon as they are large enough to handle, they will all flower the second year; seedlings sown last February I expect to bloom this June, and amongst them will doubtless be found many varieties. Mr. Ware has some interesting crosses with the yellow Columbine, half-blue and half-creamy yellow. I hope to flower this summer the new white variety of this blue *Aquilegia*. Some blooms of the normal type measured 3½ in. across.—FRANK MILES, *Bingham, Notts.*

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Showy Heron's-bill (*Erodium Manescavi*).—This has been in bloom here ever since the beginning of July, and is still continuing to open its flowers, which are something like those of a show *Perlargonium*. This *Erodium* grows about 2 ft. high, has deeply lacinated leaves, and is a plant for everybody.—FRANK MILES, *Bingham.*

Verbenas treated as Annuals.—Last year a suggestion was made in THE GARDEN to treat Verbenas as hardy annuals, sowing the seed in a bed of prepared soil, and thinning out the seedlings in due course. I adopted the suggestion and failed to rear a single plant! What has been the experience of others? Was I to blame, or the method?—H. M.

Lonicera fragrantissima at Killakee.—This Honeysuckle, trained to a wall here, blooms beautifully every year; and I find its sweet-scented white flowers very useful in a cut state. It has been in bloom since the middle of January, and it is still covered with flowers and buds. The weather does not hurt it in the least. Last season I cut flowers from it when the ground was covered with snow.—T. O'ROURKE.

Clematis cirrhosa angustifolia.—This old but nevertheless little-known plant has lately been in full bloom on walls in the open air. It is an abundant flowerer, the blossoms being white on the outside and streaked with purple inside; it also produces leaves along with its flowers, a circumstance which renders it doubly attractive. This *Clematis* deserves extensive cultivation, as it blooms from December until March without the slightest protection.—W. H. G.

Geranium armenum.—This is more beautiful than any of the hardy Geraniums with which I am acquainted. It grows about 2½ ft. high, and lasts in bloom for a long time: its large round flowers are of a rich warm purple something of the colour of Loosetrife, with a deep crimson centre. I first obtained it from Messrs. Backhouse, of York, under another name; but it is now to be had of most of the nurserymen who make a speciality of hardy plants.—FRANK MILES, *Bingham.*

* Read before the Botanical Society of Edinburgh, on Feb. 8, by Mr. J. Mc'Nab.

THE FRUIT GARDEN.

PEACH CULTURE IN MARYLAND AND DELAWARE.

If any one will examine a map of the United States, he will find a long narrow strip of land bounded on the west by the Chesapeake Bay and on the east by the Delaware Bay and the Atlantic Ocean. This peninsula is nearly 180 miles long and from 20 to 50 miles wide, and comprises nearly the whole of the small State of Delaware, two counties of Virginia, and what is known to us as the eastern shore of Maryland; not only is it nearly surrounded by salt water, but many small rivers and sounds indent the whole peninsula, and I do not know a tract of land of the same size that has such fine water communication, it being stated that there is not a farm that is over 10 miles from navigable water. The vicinity of so much water gives the climate a mildness not found in the same latitude in the interior. The whole land is no doubt a very late upheaval, and at no great length of time formed a part of the ocean bed, large beds of oyster shells and marl being frequently found. The land is quite free from rocks and stones, and perfectly level, which renders it easy of culture. It was an early settlement, and under the old slave régime produced the finest Wheat and corn, and all kinds of fruits and vegetables in the greatest abundance.

But it was not to describe the natural advantages of this tract of land (advantages which have long ago gained for it the name of the Garden of Maryland, Virginia, and the neighbouring States), but to give a slight description of the culture and preserving of the Peaches, which cover thousands of acres of ground, and give occupation to thousands of men, women, and children. It has been famed for its Peaches from time immemorial, and has long supplied the cities of Baltimore and Philadelphia, and the surrounding villages with this fine fruit. But the fast freight trains, the canning process, and the demand in the newly-settled West has given an impetus to Peach planting which has made it a great industry. I have not at hand the statistics for 1876, but in 1875 there were shipped by rail and steamboat over 8,000,000 baskets of Peaches, exclusive of those sent by small sailing vessels, canned or used on the farms, or distilled into Peach brandy. As these baskets each contain 2 pecks, it will be easy to imagine what large facilities must be provided for the transport of such a quantity in so short a time as from the last of July till the first of October.* Well-ventilated cars are built expressly for the transportation of Peaches, and the boxes are placed so that a free circulation of air is kept up between the tiers. On arrival at Baltimore or Philadelphia many cars are dispatched northwards to New York, Boston, Portland, and as far west as Chicago and the intermediate cities and larger towns. I have made a calculation that the packers of canned fruit use at least 30 per cent. of the Peaches, and as they need the firmest and best fruit for their purposes, they give the highest prices. The ripe fruit is sold for immediate uses, and often at much lower figures. I think that the average price for prime Peaches last summer (1875) was about 4s. a box of 4 pecks, and ranging from that price down as low as 1s. per box, according to condition, &c. Good Peaches, but too soft to can, were sold retail in the streets at 10d. per peck. The fruit is put up in 2-lb. and 3-lb. cans, and I should think a bushel of Peaches would fill eighteen 2-lb. cans. The process of canning Peaches is so simple that the majority of cultivators put up enough for their home consumption.

Any land that will produce from 20 bushels to 25 bushels of Wheat to the acre will do for Peaches. Most growers now raise and bud their own trees. The stones are put in a hot-bed, and as soon as the kernels have started and commenced to shoot, if the weather be warm enough, they are placed in nursery rows 1 ft. apart. By September they will be large enough to bud, and at the end of the second year the trees will be from 3 ft. to 4 ft. high, and large enough to plant out. They are generally planted about 20 ft. each way, taking over 100 to the acre. The trees commence to bear the third year after planting out, are in their prime about the sixth, and last about twelve years. It was customary to plant Maize between the rows until the trees interfered, but now good fruit-growers

work the orchard as a crop, keeping it clear of weeds and Grass. The tall growth of the Maize no doubt interfered with the progress of the trees, and the immediate gain proved a loss in the end. Even after the trees come into fruiting the ground is kept clean, as a Grassy orchard soon runs out. In fruitful years immense quantities of props are required, in fact, to such an extent as to make them quite an item of expense. Large trees have been known to bear 5 or 6 bushels, but two and three boxes to a tree is a nearer average. Farms having 100, 200, or 300 acres in Peaches are common; Col. Wilkins, of Kent, has over 1000 acres, and has a steamboat of his own to convey his fruit to market. Many cultivators have distilleries and turn their specked or small fruit into brandy. It takes from three to five bushels of Peaches to make a gallon of brandy. If the season be warm and dry, with only moderate rains, the fruit is less watery, and contains more saccharine matter than in wet seasons. Very few of the varieties known in England are cultivated here. Early York, Grosse Mignonne, William the Fourth, and a few French kinds are sometimes met with. Some of Mr. Rivers' varieties are now attracting attention on account of their early maturity, but, as a general rule, American seedlings suit better, and so easily are excellent varieties grown from seed that new ones are annually making their appearance. The principal drawbacks to the cultivation of the Peach on this peninsula are late frosts and sleet coming when the trees are in blossom or flower-buds much swollen. They are also troubled with a worm that bores into the tree just at the ground, and which has to be destroyed by running a wire into the hole. The Peach thrives best near tidal water. With regard to the quality of the fruit, I have never met with superior, and rarely the equal, of the Maryland Peaches in any part of the world. A great part of the fruit, which is only of medium quality, would be prime if some attention were paid to thinning it when small, the low price at which it is sold not permitting the employment of skilled labour to thin the fruit at the proper season. But the high price which fancy fruit commands in the markets of our larger cities is attracting the attention of the fruit-raisers. Some extra fine fruit for the fancy fruit-stands brought as much as 8s. per box at the time the best canning fruit was worth only 4s., but only a moderate quantity of such fruit could be sold. An attempt was made last summer to ship a lot of Peaches to Liverpool, though owing to want of ice or some other cause they all rotted; but I believe that all difficulties for the safe transport of fruit will be overcome ere long. The Peach Association of this peninsula reckon by the number of baskets of half a bushel each, though a great part is sent to market in boxes containing 1 bushel each. The pickers are paid so much a basket.

CHAS. H. SNOW.

Setting Muscat Grapes.—Many different methods have been resorted to to assist setting in the case of Muscat Grapes, such as the use of the camel's-hair pencil, rabbit's tail, and drawing the dry hand over the bunch after it had been drawn over that of a Ham-burgh or some other free-setting sort. None of these aids to setting are, however, of any use unless attention be paid to the thorough ripening of the wood the previous autumn, and to keeping up a healthy root-action while the Vines are in flower. Muscats being naturally free growers and liable to make gross wood difficult to mature, should always be planted in a well-drained border, in a compost consisting of good, strong, fibrous loam, without any mixture of manure. The latter should only be supplied to the roots in a liquid state whenever the Vines require it. Muscats, too, require plenty of water during the growing season. If these points be attended to and a genial atmosphere of from 70° to 75° maintained when the Vines are in bloom, a crop may be depended on.—JAMES SMITH, *Waterdale*.

How to destroy Moss on Fruit Trees.—Your correspondent "J." (see p. 59) wishes to know the best way of destroying Moss and Lichen on fruit trees. I have found sprinkling them with fresh powdered lime on a damp, not a wet day (on a dry day the trees should be syringed), will kill Moss without injuring the trees.—W. W.

Late Winter Pears.—Ne Plus Meuris, Glou Morceau, and Easter Beurre have one and all been unusually good with me this season; the fruit of Glou Morceau, grown on cordons on south walls had skins like gold, and the flavour was excellent, equal to that of Bergamotte d'Espéren, and far better than Winter Nelis here.—R. GILBERT, *Burghley*.

*This account is official (1875); it was by far the largest crop ever raised.

HARDY FLOWERS IN LONDON GARDENS.

SPRING-FLOWERING bulbs, which are unusually forward this season, are, owing to the few sunny days which we have had, both gay and attractive. The Crocus beds in Mr. Barr's grounds at Tooting exhibit a profusion of rich and variously-coloured blooms, and flowers of the single blue and white and double red Hepaticas sparkle under a group of Poplar trees near which they are planted. In this position, too, Polyanthus Golden Plover is a mass of large, bright yellow blossoms, and the Alpine Windflower (*Anemone alpina*), to which we referred a few weeks back, is still in excellent condition on raised beds.

Helleborus niger.

The Scarlet Windflower (*Anemone fulgens*) is just opening its brilliant crimson-scarlet blossoms, thrown well up above dense masses of lively green foliage; and *Anemone blanda* is furnished with an abundance of large sky-blue flowers. *Scilla sibirica* and *S. biflora* are still very beautiful in Mr. Parker's nursery, where are also little clumps of a *Scilla* quite distinct from other Squills; its flowers are light blue, and are in denser masses than those of other kinds. Established plants of *Iris stylosa*, too, are flowering freely, and when these become plentiful they will no doubt be extensively cultivated: few hardy plants will be found more useful than this for furnishing a supply of beautiful sky-blue blossoms for floral decorations

Helleborus purpurascens.

during the early spring months, and they last in water for a long time in good condition. Beds of *Iris reticulata purpurea* are likewise just now thickly studded with fine, dark-purple, yellow-striped blooms at Tottenham and Tooting, and plants of *Cyclamen Atkinsi*, growing among the Grass under trees in warm situations, are more beautiful now than they have been all the season. *Sisyrinchium grandiflorum* and *S. album* are full of deep purple and white blossoms with dark golden anthers in Ware's nursery, and beds of the Snowdrops (*Galanthus Imperati* and *G. plicatus*) are covered with flowers. The Great Pilewort (*Ficaria grandiflora*), too, is just now very showy, its large glistening yellow blossoms being borne in great numbers. For growing under trees and shrubs this plant deserves extensive cultivation, for where many other plants fail in such positions, this will invariably flourish and flower freely

for several months in the spring; and the same may be said of the golden-flowered Winter Aconite (*Eranthis hyemalis*). *Saxifraga rubra*, *ciliaris*, and *Ingelrestis* are also plants that are now very attractive in the Tottenham nurseries, their rose-coloured blossoms being produced in large compact heads, and surrounded by ample, stiff, bronzy-green leaves. Here, too, the Rosy Rock Cress (*Arabis blepharophylla*) is producing its showy rosy-coloured blossoms on raised beds in abundance, and the Lungwort (*Pulmonaria affinis*) is loaded with bluish-pink, Cowslip-like flowers. The Spring Starwort (*Triteleia uniflora*), notwithstanding that it has been covered with bloom for several months past, is still bearing quantities of beautiful lilac-striped flowers. The bright blossoms of a yellow Wall-flower are now opening in quantities, and fill the air with their fragrance. The purple flowers of *Rhododendron præcox* are also becoming very attractive; *Gentiana acaulis*, too, is, as has been the case all through the winter, bearing numbers of its large, deep blue, vase-like flowers from amidst a thick carpet of glossy green leaves. *Frimula denticulata*, should the weather be favourable, will soon be at its best; but the continuous heavy rains which we have lately experienced have made great havoc amongst hardy perennials, as well as amongst bulbous-rooted plants of every description. Nearly all kinds of Lilies have started into active growth, and if not in some way protected, will be liable to be cut down by spring frosts

Primula denticulata.

Primula vulgaris.

should they set in with anything like severity. The Giant Christmas Rose (*Helleborus lividus*) is pushing up its massive bloom-buds, and will shortly be very effective; when planted in open places in shrubberies or in a raised position on mounds, this plant is very conspicuous when in flower. Other Christmas Roses are also in full bloom, and *Iberis semperflorans* is this season flowering earlier than usual on account of the mild winter which we have had. S.

English Irises.—Is there anything more lovely in this lovely world of ours than a bed of *Iris anglica*? Go to Tottenham about the middle of June and see all the describable and indescribable colours blended together in a bed of these Irises. I think the most beautiful variety of all is Bronze Queen, and I know of no flowers more inexpensive in proportion to their beauty. They should be planted in sandy soil on a raised bed early in September. Underneath the sand put quantities of rich vegetable matter or thoroughly decayed cow manure. Perhaps it is well these wonderful beauties do not last long enough to put us out of patience with flowers of a mere enduring kind.—F. M.

Campanula coronata alba and other Bell-flowers.—A plant for all time and for all gardens is *Campanula coronata alba*, than which no hardy plant is more wonderful, with its white calyx looking like a white reflection of the greater flower. There are, however, many other Bell-flowers to be revered and rejoiced over. *C. Hosti* is a fine dark-coloured and stronger-growing variety of the common Hairbell; the white variety, *C. Hosti alba*, is far finer than the white variety of *C. rotundifolia*, though that is a first-rate border plant. *C. lactiflora* is delicate in colour and stately in growth; *C. turbinata* is a fine dwarf plant for the edge of a border; *C. pulla*, when growing well in moist, turfy loam, is thoroughly beautiful and very dwarf.—FRANK MILES, Bingham.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Stoves.—There are many subjects here that will now want attention in the matter of re-potting. It is always advisable to get on with this work as soon as the plants are ready for it, as by so doing time is saved later on; it will be well to give the majority of the ornamental-leaved varieties a shift. Crotons need more drainage than most hard-wooded plants; they should also have a good layer of fibrous material put over the crocks. If the drainage be not very good the soil soon gets too wet, as these plants want a deal of syringing to keep down yellow thrips where it exists. Bertolonias and Fittonias are beautiful small plants well worth cultivation; the Fittonias especially will succeed in places where few plants will prosper. It is time now to start Caladiums; they should be taken out of the old soil and re-potted in fresh, consisting of good loam to which has been added a little sand and some leaf-mould. Where desirable, they can be increased by dividing the bulbs, leaving to each piece part of the crown with buds. For all decorative purposes plants of a comparatively small size will be found more useful; put them in heat as soon as they are potted. Where sufficient space can be afforded for its full development, *Medinilla magnifica* is a fine plant for decoration; the temperature of an intermediate-house, say 50° by night, will be the best for it at the present time; if it be kept too hot it will be likely to cause numbers of the flowers to drop, neither should it have as much moisture in the atmosphere as many stove subjects require. Plants that were ripened well in the autumn will break out and bloom from the back wood as well as from the points of the shoots. Those who are fond of strange-looking flowers will do well to give *Aristolochias* a place; they grow rapidly, and can be had in a blooming state in twelve months from the time of the cuttings being struck, and they do not need much care. Plants that are in little pots ought to have a shift; they may have 6 in. or 8 in. more room; pot in good loam, to which add some leaf-mould and sand; they need a liberal supply of water; syringe every day as they are liable to the attacks of red spider if allowed to become too dry overhead. Their flowers show to advantage trained over a path, in which way they can be grown; or the shoots may be trained round a trellis, taking care to keep the points higher than the other parts; if this be not done they will stop and break out into fresh growth, which generally is not desirable if the plants be not weak and so need strengthening.

Bedding Plants.—Attend diligently to the propagation of these. If there be a scarcity of autumn-struck *Pelargoniums* strong shoots taken off in one good length and put in a little heat will strike well, and become fair-sized plants by bedding-out time. Cuttings struck in the autumn should be potted off and encouraged to grow by giving them a night temperature of 45° or so.

Ferns.—A commencement should be made in potting Ferns, for if this operation be deferred too long, the young growth gets checked and becomes deformed. Whether we take into account their beauty, their value, or their unsurpassed elegance for mixing with cut flowers, *Gleichenias* have few equals and no superiors. Fully matured fronds when well supplied with water, will last in a cut state for an almost incredible time; of course the young immature fronds will, as in the case of other Ferns, shrivel very soon. It is not advisable to cut plants that are small; but they are not very difficult to grow, and when they attain a good size, which they will in a comparatively short time, there need be no fear of cutting to a reasonable extent. In getting in young plants, it is necessary to be extremely careful that they are perfectly free from both scale and mealy bug, for if either of these pests exist on them, they cannot be grown in a way to show their true character. Whilst the plants are small, the insects may, by unceasing attention, be kept down; but as they get larger, the sponge and brush, however carefully applied, prevents their progress satisfactorily. If healthy plants be treated as hereafter recommended, they will grow quickly. The soil in which they are grown ought to consist of five parts of the best fibrous peat broken into pieces about the size of hens' eggs, one part clean sand, and one part coal cinders about the size of Acorns. As they have creeping rhizomes that will extend a long way in all directions, broad and somewhat shallow pans are better than deep pots in which to grow them; these, according to the size of the plants, should be filled to within from 6 in. to 10 in. of the rim with drainage, pressing the soil moderately firm. They must not be syringed overhead, but the roots need a good supply of water; they succeed best in a drier atmosphere than that usually allotted to many Ferns. Let them be placed where there is plenty of light and not far from the glass. They do not want to be kept very hot—from 45° to 50° night temperature in the winter, and 5° higher by day, will do, with 10° or 15° more in the summer, admitting a moderate amount of air and slightly shading them.

Solanums.—Where these are grown from seed it is quite time to commence sowing, or else the plants will not have time to form their berries and get them well coloured before winter. Sow the seeds either in pots or pans containing a mixture of two-thirds loam and one-third sifted leaf-mould and sand, putting some of the finest of the soil on the top. They will soon begin to grow, when they must have a place near the glass to keep them from drawing; directly they are of sufficient size to handle, put them singly in small pots.

Vineries and Peach-houses.—Those amateurs who have more than one Vinery may now start one, letting the temperature at the beginning be 50°, syringing the Vines morning and evening, and admitting air during the day. A house like this will be very serviceable for other subjects. If the Vines be young, do not tie them in their places till the shoots are 1 in. or 2 in. long; this treatment will encourage them to break freely at the bottom. Where Peaches are grown in houses with the assistance of fire-heat, they should be started now, keeping the night temperature at about 45°, and giving air in the middle of the day; close the lights in good time in the afternoon, and syringe the trees well. At no time must the house be permitted to get too hot. Be careful that the soil is moist down to the depth of the roots.

Frames.—The fermenting material as recommended for hot-beds will now be ready for making up. The length of time that the beds will retain their heat depends materially upon the position they occupy; they should be well sheltered from the wind, and so placed that they will receive every ray of sunshine; it is also important that there should be no water standing about them, as this has a great tendency to cool them. If they must occupy an exposed situation, litter around the sides, shielded by means of wooden shutters from both rain and wind, will afford a good protection. It is better at first to make a bed for only a single-light frame, using this for Cucumbers till they are fit to plant out into a larger one. A bed made at this season ought to be 3 ft. longer and wider than the frame, and as it will settle one-half it should be 4 ft. 6 in. high when finished. Put on the frame directly and raise the lights at the back about 2 in. to allow the escape of the steam. As soon as the heat drops to 80° sow the seeds in little pots, two or three in each; when up, keep them near the glass, and in mild weather give air in the daytime, putting a double thickness of mats on at night. This bed will be useful for striking bedding plants. Beds for Potatoes and Carrots must not be so deep as for Cucumbers; 2½ ft. high will do well, on which place 10 in. of soil. The heat in the centre of the bed should not be more than 70° when the Potatoes are planted; let the rows be 14 in. apart, putting the tubers 4 in. deep and 10 in. asunder in the rows. Carrots ought to be sown in rows 8 in. apart, covering the seed with about ½ in. of soil.

Kitchen Garden.—Directly the first-sown Peas are above-ground, make another sowing of some other early kind; also put in some second early, such as *Collingford's Champion*, thereby securing successional crops. In those parts of the country which are unsuited for sowing Peas, Broad Beans, Radishes, &c., at the beginning of the year, it is time now to get them in.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

February 19.—Digging land for Cabbages and Cauliflowers. Sowing Sweet Peas. Sowing Fulmer's French Beans in pots in heat. Sowing Radishes out-of-doors. Sowing Radishes in frames planted with sprouted Potatoes. Sowing Onions and Leeks. Potting off plants of Oxalis; also *Chrysanthemums*, and placing them in cold pits. Shifting a few Ten-week Stocks into 6-in. pots. Pricking off *Viola cornuta*; also spring-sown Cauliflowers in frame. Going over East Indian Orchids, using Sphagnum, and *Lycaste*, giving the latter some peat, sand, and horse-droppings, and finishing with Moss. Putting in cuttings of *Bouvardias*, *Fuchsias*, scented *Pelargoniums*, *Verbenas*, and *Dracenas*. Getting baskets for conservatory planted with *Nemophila*, *Saponaria*, Musk, and *Creeping Jenny*. Planting Globe Artichokes for autumn bearing. Putting Feverfew into orchard-house. Putting up wall tree protections. Looking over *Phalaenopsis* for thrips, also over other Orchids on which insects are suspected to exist. Giving a top-dressing and more leaves to pot Vines. Manuring Rose garden beds; also Globe Artichokes. Earthing-up seedling Asparagus bed in order that it may be hoed over without injury to the crowns. Pruning espalier Apple trees. Stopping *Calceolarias*. Cleaning *Viola* and Asparagus beds. Keeping *Phalaenopsis*-house regularly at 70° at night. Raising East India-house to 70° at night; *Dendrobium*, 60°; *Cattleya*, 60°; *Lycaste*, 55°; and *Odontoglossum*.

house, 55°. Raising second Vinery to 58° at night, buds mostly burst, and some showing fruit. Keeping first Strawberry-house to 60° at night, and second Strawberry-house at from 55° to 58° at night. Plants ready for house decoration:—Tulips, Hyacinths, Narcissus, Lily of the Valley, Crocuses, Forget-me-Nots, Snowdrops, Cyclamens, Dentzias, Callas, Primulas, Ghent Azaleas, Lilacs, Rhododendrons, Mignonette, pink and scented Pelargoniums, Sweet Brier, and Gardenias.

Feb. 20.—Potting bulbs of *Lilium anatum* and plunging them in sand outside; also autumn-struck Verbenas and Dielytras for next year's forcing. Pricking off Capsicums. Putting in cuttings of Mangles' and Christine Pelargoniums; also some scented Verbenas and Heliotropes. Planting Potatoes under the protection of a south wall. Putting in another forcing of Asparagus. Putting Artemisias out-of-doors. Boxing Ageratums and putting them into Vinery. Putting young Mignonette on sunny side of pits. Examining Rose-tree ties and re-staking them where necessary.

Feb. 21.—Putting *Oncidium Lanceanum* into baskets drained with wood placed crosswise. Plunging *Centaurea* cuttings just put in into bottom-heat. Gathering French Beans in good condition from second sowing. Digging in manure amongst Gooseberry trees. Manuring Strawberries. Top-dressing Calceolarias with a good layer of cow manure; also Peach trees, Apricots, Pears, and autumn Raspberries. Putting soil consisting of four parts loam and two leaf-soil into Cucumber-pit. Hoeing among young crops.

Feb. 22.—Cleaning walks. Slightly increasing atmospheric moisture in Orchid-houses. Sowing Parsnips; also Radishes under the protection of a wall and netting them. Potting off Petunias and placing them in Peach-house; also Lobelias, Adiantums after division, Gazanias, and Achimenes. Pricking out more Lobelias, Celery, and Cauliflowers, the latter in a two-light box. Putting *Oncidium flexuosum* on Tree Ferns; also *Saccolabium* in baskets and hanging them up.

Feb. 23.—Sowing London White Cos and Malta Drumhead Lettuces; also Champion of England and Veitch's Perfection Peas, Broad Windsor Beans, Spinach, Dutch Forcing and Early Horn Carrots on south border, and Early Dutch Turnips. Shifting Golden Chain Pelargoniums into 6-in. and 8-in. pots, putting three or four plants into a pot, in order to make large plants, and placing them in heat on Vinery shelves. Potting Heliotropes. Filling all spare cases with Cauliflower plants. Planting Jerusalem Artichokes. Preparing a pit for first Melons. Making ready cradles for the protection of tender bedding plants. Starting third Peach-house at 55° by night.

Feb. 24.—Potting last autumn-struck Fuchsias into 32-sized pots for early flowering. Potting spare Cucumber plants in case of accident. Shaking out old Scarlet Pelargoniums and re-potting them. Re-potting or top-dressing (as may be necessary) the *Phalœnopsis*, using Sphagnum. Sending in the first Reinette du Canada Apples and Colmar Pears. Manuring Orchard. Clipping Ivy on walls. Thinning first Muscats.

Orchids.

It is desirable to have as many leading growths as possible to an Orchid, because the more leading growths a plant has the greater quantity of bloom it is capable of producing; but as Orchids, even in their native habitats, exhibit a tendency to continue their growth from that last made, rarely producing back breaks, unless in the case of a very large plant, or that of injury to the leading growth, or the rhizome between the pseudo-bulbs (of pseudo-bulbous kinds), it is the practice under cultivation to resort to artificial means to induce them to break back, and the present time is the best for performing the operation. With respect to *Aërides*, *Vandas*, *Saccolabium*, *Angrœcums*, &c., it is a common thing to see vigorous plants having several young ones at their bases which do not seem to grow so freely as could be desired, while the main stems grow vigorously; the fact is, that the main stem, which is essential to the offshoots at the base until they are strong enough to root and support themselves, afterwards takes a considerable portion of the nourishment which should be devoted to them. With such plants it is best when the young ones at the base begin to root, to cut a notch half-way through the stem at its base, and just above that point from which the offshoots spring; later in the season, after the young plants are well rooted and established, the severance should be completed at the same point. With plants of the class referred to it is often hazardous to attempt to produce back growth on a plant not showing signs of young growth at the bottom by making an incision in the main stem, but after the growth has been produced, it is very beneficial to do so. *Cattleyas*, *Lælias*, *Oncidium*, &c., having five or more pseudo-bulbs, may have a notch

cut half-way through the running stem between the pseudo-bulbs without waiting for any other sign of back growth than a plump eye in front of which to make the incision, care being always taken that not less than two pseudo-bulbs are left on each piece intended to be severed, and that the severance is not completed until the back growth has shown itself to be sufficiently strong. In this way large specimens of Orchids may be obtained which are known to be from one piece, and consequently bearing flowers exactly alike, a consideration which greatly enhances the value of a plant. Different plants of the same species of most Orchids, particularly *Cattleyas*, *Lælias*, and *Odontoglossums*, are so unlike each other in their flowers, that specimens made by putting a number of smaller plants together, generally present a motley appearance when in blossom, even if brought to flower at the same time, which can seldom be done.—

JAMES O'BRIEN.

Protecting Roses.

This winter being so mild, Roses in many places have started into full growth, and should frost occur, they will suffer more from it than most kinds of flowering shrubs. Those who have pruned their plants in autumn in such a season as this will have to take great care of them. Roses as a rule should not be pruned before March. Many of them have made young shoots from 2 in. to 3 in. long, and the old Monthly Rose is coming into bloom, and the question is—What is to be done if sharp frost sets in? My advice is, keep plenty of hay and straw bands in readiness, and dry litter, with which to cover the dwarf Roses, so as to thoroughly protect them. If this be not done, we may expect to lose a great many valuable specimens. On referring to weather records of past years, I find that when December and January have been very mild, we have generally had sharp weather at the end of February and early in March; therefore, there is nothing like being prepared for covering up at even the shortest notice. Frost is always most destructive to Roses when the sap is up, as it is this season. The branches frozen being full of sap, the vessels get ruptured, and great damage is the result.—G. II.

Miscellaneous Plants.

Auriculas in pots are now beginning to grow, and the buds are already beginning to show themselves in the axils of the leaves. The plants should still be kept pretty dry, and the surface soil occasionally stirred. In well-established plants there is the promise of a fine bloom. The choicer varieties of Carnations and Picotees are invariably wintered in pots; they are too precarious in constitution to remain out-of-doors all the winter. At this time of year the old leaves decay, and should be kept cut away with a pair of scissors, or the decay will sometimes extend to the stems and destroy the plants. In mild weather aphides will cluster about the points of the foliage, but dipped in a solution of Fowler's Insecticide they will soon be destroyed. Plenty of air is requisite to keep the plants stocky and robust. Double Daisies in beds now require looking after, as the worms sometimes raise them out of the soil, into which they should be pressed firmly; strong plants are already throwing up their flower-stems; the earliest a pretty mottled crimson variety named Little Gem. Plants of *Mimulus*, in pots, held over from last year, are beginning to grow; but they are apt to get much infested with deep green fly, and, the leaves fitting so close one above the other, it is difficult for the fumes of Tobacco to find their way to them. It is a good plan to make a solution of soft soap and sulphur in warm water, and dip the plant into it. Those who make a point of planting out strong Petunias early in summer, sow their seed in autumn, so as to have them well advanced in spring. The seed-pans should now be covered with young plants, which should be kept near the glass, but not in a too dry place; they should be shaded from sunlight, and the surface should be kept moist. Pelargoniums of the large-flowering, or show class, as they are termed, now require attention, as the plants potted in October are, owing to the mild weather, making active growth. They need a dry, cool, and airy position, and careful watering, not too much to induce a rapid sappy growth, or too little to cause a loss of leaves. The principal shoots, if too long, may be cut back 1 in. or so, which will cause the plants to break freely a month or so hence. The fancy varieties should be kept cool, but in a warmer atmosphere than the large-flowering varieties; they are more delicate, and at this time of the year should not be kept too moist at the roots. The zonal varieties which have been blooming through the winter require to be well looked after as regards watering in order to maintain a head of bloom. Single and double Primroses both in pots and in the open ground are growing fast and commencing to flower. One great advantage in having them in pots is that the flowers are protected from frost and rain, and they last much longer under glass; the more genial atmosphere makes the flowers of large size, which is another advantage. In the open ground vermin spoil the flowers. Polyanthuses in pots are also getting active, and require to be continually well watered.—D.

CYCLAMENS AND SUN-HEAT.

"CHRISTINE" does not say (see p. 106) what species of Cyclamen was seen by her in the neighbourhood of Athens, but probably it was *C. hederifolium* or one of its varieties, the growth and general habits of which are somewhat different from those of *C. persicum*, to which alone my remarks had reference. The Cyclamen may, as far as I am aware, be found growing naturally under very varied conditions, but whenever I have myself seen it in its native habitat, the corn has been well buried under the soil and well surrounded by herbage. I have found *C. europæum* in positions somewhat analogous to those occupied by our native Primrose, which, although enjoying a free circulation of air and abundant light, has its crown protected from hot weather by the herbage amongst which it grows. Thus placed, the roots of the Cyclamen strike down into the damp sub-soil and preserve their vitality, and the covering of soil is alone sufficient to protect the corn and crown, whence issue the new leaves and flower-buds, from the burning sun and drying air; consequently the vital parts of the plant are kept comparatively cool and moist, and are therefore insured against sudden vicissitudes of climate. Although apparently at rest, if examined during the summer Cyclamens will be found to be forming fresh growth underground, so that when the cooler season arrives they may push up strongly through the surface soil. The placing of the Cyclamen in a position where the root and bulb are fully exposed to a burning sun and an arid atmosphere appears to me to be as unnatural as it is useless. As "Christine" will observe, there is a wide difference between a plant standing in the open ground, where it enjoys a free and extensive root-run in a cool bottom soil, and a plant in a pot confined to a small portion of soil, upon which the sun has full play. Pot culture is more or less unnatural, and it is only by using judgment in warding off extremes that we are enabled to succeed in the culture of plants under such circumstances. Many plants which will endure, and even prefer, the full blaze of the summer sun when placed under natural conditions, must, if grown in pots, be afforded protection from excessive heat. In stating that exposure to strong solar warmth was foreign to the nature of the Cyclamen, I, of course, referred to the plant in its entirety, and not to the foliage alone. The peculiar manner in which, as soon as the seed is formed, the flower-stem commences to bend downwards, and eventually buries the seed-pod somewhat deeply in the soil, affords a convincing illustration that the plant naturally (so to speak) seems desirous of guarding itself against vicissitudes of climate; it is worthy of note, too, that if the flowers fail to set, the stalk will not bend towards the ground, but remain in its normal upright position.

JOHN CORNHILL.

Effect.

Bottom-heat Injurious to Camellias.—There is an important point mentioned in the excellent article on Camellia culture in your last issue (see p. 106), on which rather more stress might have been laid, and that is, the evil of trying to force the Camellia, especially by means of bottom-heat. I believe, that of the numbers of Camellias killed annually more die from this cause than from any other, except insufficient watering. When placed in heat quantities of fresh roots are formed, which, however, soon decay, leaving the foliage yellow and miserable, an appearance which it keeps all the season, and the following autumn the flower-buds, instead of expanding, turn brown and fall. Another idea suggested by reading the paper referred to is, that your correspondent gives no data by which a person ignorant of soils may know whether he can grow Camellias or not, and they will not grow in all soils, especially if they contain lime; the nature of a soil may be best known by the character of the vegetation growing upon it. The turf from a soil in which Rhododendrons, Azaleas, or Foxgloves, grow freely and vigorously will also answer for Camellias, if the instructions given on page 106 be carefully followed.—C. E. PEARSON, *Chilwell*.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Eurya latifolia variegata.—This, although not altogether new, is far from being as common as it deserves to be. Its close-growing, shrubby habit and handsome, striking foliage render it well adapted for the winter decoration of cool conservatories, where the scanty stock of flowers has to be set off by, and contrasted with, bright, handsome foliage.—E. HODDAY.

Myosotis dissitiflora in Pots.—Where spring flowers are in demand—and where are they not?—this beautiful Forget-me-not is indispensable. Any body with a greenhouse, or even a frame or a good light window, may be gladdened by its numerous miniature blue star-shaped flowers. The best way to grow it is to sow the seeds thinly on a partially shaded border about the end of August, and during the winter lift the strongest with balls of earth and pot them into 48-sized pots. Place them in a cold frame, ventilate freely, and water when necessary. In January move a few at a time into a warm light greenhouse.—E. HODDAY.

PLATE LXI.

THE FORGET-ME-NOTS.

(WITH A COLOURED FIGURE OF MYOSOTIS RUPICOLA).

Drawn by H. NOEL HUMPHREYS.

THE genus *Myosotis* is one that has long enjoyed a wide popularity under its more familiar and poetic English title the Forget-me-not. In the language of flowers it may be said to stand without a rival as regards the sentiment which beams forth from its bright blue blossoms; and in truth, setting aside all poetic fancies and the legendary lore with which the origin of the name is associated, it has an intrinsic beauty of its own which few plants possess. This will be admitted by every one who has seen—and who has not?—the masses of azure blossoms which fringe during the summer the margin of almost every streamlet, the produce of the Marsh Forget-me-not (*M. palustris*), one of the most widely distributed of our wild plants. Again, those whose rambles may have extended through the sylvan groves with which our mountains are clothed, in the glad months of May or June, must have been equally struck with the light, airy elegance that the sprays of the Wood Forget-me-not (*M. sylvatica*) assume—the former basking in the full sunshine of the long midsummer's day, the latter revelling in the partial shade which the fresh expanded foliage of the overhanging branches furnish. Then again, in the Scattered-flowered Forget-me-not (*M. dissitiflora*), we have one of those primary elements of beauty, in the absence of which our spring flower gardens would be robbed of one of their brightest features; here the true, fully developed azure colour of the flowers is preceded by a roseate blush. Familiar, however, and lovely as these are, we have in our Rock or Alpine Forget-me-not (*M. rupicola*), which is the subject of the annexed illustration—the gem of them all—a plant in which the maximum of beauty appears to be concentrated into the minimum of space—a characteristic, by the way, which is applicable to many of our Alpine plants. Here we have a plant scarcely exceeding 2 in. in height, whose dense flower-heads rise from a cushion of compactly-arranged, green leaves, each of which appears to be supported on a foot-stalk, owing to the blade of the leaf tapering somewhat narrowly down towards the base. The flowers are of a slightly darker tint of blue than any of the species just named; and when I apply the word "large" to them, it ought to be qualified by the assertion that they are large when compared with the size of the plant; added to this the beauty and richness of the blue is not a little enhanced by the golden eye which appears to lighten up each individual flower, and, while adding beauty to the mass, attracts the attention irresistibly to the individual details of which the mass is composed. The true *M. rupicola* is usually considered as synonymous with *M. alpestris*, and the latter with *M. suaveolens* of Waldstein and Kitaibel; doubtless the synonymy of the latter two is correct, but I have a strong opinion that the plant here figured is quite distinct, specifically speaking, from the *M. alpestris* of the Scotch mountains. The plant as found growing on the Micklefell, one of the highest of our Yorkshire hills, scarcely exceeds 1 in. to 2 in. in height, whereas the Scotch plant attains as much as 6 in.; moreover, the radical leaves in the latter are much more distinctly stalked, broader, and of a darker green. I may further add that my opinion on this matter is entirely confirmed by the distinctive habit the plants retain under cultivation; in the Yorkshire plant scarcely a trace of seminal variation presents itself, while, in the Scotch plant when raised from seed under the more generous treatment, which it experiences in garden culture, it is liable to increase both in vigour and stature so much so as almost to lead us to endorse De Candolle's and Koch's opinion that it is nothing more than an Alpine form of our Wood Forget-me-not. Be that as it may, the *Myosotis*, to which our attention is at present specially directed, as a rock plant is, when grown as Messrs. Backhouse grow it, exquisitely beautiful, and the rock-garden is its true position; as a rival to the *M. dissitiflora* of our flower gardens, its later period of blooming (May and June), its exceedingly dwarf habit, and its want of vigour, are all militating elements. In the rockery it should have a north aspect with perfect exposure, and its cultural success

MOUNTAIN FERRET MEADOWS, GLEN FERTICHA, IRELAND.

will be much more certain if with a mixture of ordinary loam and peat, a quantity of nodules of limestone be incorporated, to which geological formation it appears to have a special affinity.

The Azorean Forget-me-not (*M. azorica*) is a charming species, and unique in its semi-shrubby character. Some thirty years ago, when first introduced, it received a well-deserved recognition, and appeared without any difficulty to establish its claim to general, and I may add successful culture. Being a native of the extreme western islands of the Azores, as might be expected it proved too tender for outdoor culture, unless it might be in very exceptionally sheltered localities. The extreme beauty of its dark flowers of the richest indigo blue with a well-marked dash of purple in it as well—combined with the successional manner in which the flowering branches are produced, gave it a well-merited claim for indoor spring decoration; under these conditions it grew vigorously, whether raised from seed or by cuttings. From some cause or another, for which I could never account, it gradually disappeared. The debilitated condition of all the plants I have raised for some years past, however, seems to point to the possibility that they originated from immature and only half-ripened seed, a supposition in which I am in some measure confirmed by the fact that the seeds were extremely small, and altogether lacked that plump character which they used in olden times to possess. Possibly these remarks may be the means of bringing to mind its former beauty and popularity to those who have cultivated it, and rouse in them the wish to possess it once more. Surely there need be no difficulty in obtaining a supply of good seed from its native habitat. I may further add, that a variety called Imperatrice Elizabeth, and several others of Continental origin, lay claim to a parental relationship with this Azorean species.

JAMES C. NIVEN.

Hull Botanic Gardens.

The Double Poinsettia.—Anxiety to multiply this Poinsettia to the utmost has prevented me, like many others, from reaching perfection in the cultivation of this plant this year; I have, however, flowered it sufficiently well to discover its merits. Though no doubt like the common variety, the size, colour, and even the number of the floral leaves or bracts, will depend very much on the strength and vigour of the plants—these are the points, in addition to the multiplicity of the bracts, that recommend this new variety to cultivators. It is of a much deeper colour than the ordinary Poinsettia, and it continues more than double the length of time in bloom. I have had a head of the double kind in flower for two months, and the longer it continues in bloom the more beautiful it becomes. The colour is also much more vivid than that of the common variety growing in the same house. Naturally, too, or perhaps this may be the result of severe propagation, this new kind seems much later than the old type, a fact which, if established, will add to its value. I am of course aware that the time of flowering Poinsettias is a matter of treatment, and that they may be had in bloom from November to May; still, under ordinary treatment, the harvest of Poinsettia beauty is mostly reaped in December, and it will be a great gain if subjected to the same conditions, the new variety will continue its beauty all through January and February; the bracts, in fact, seem to form in succession rather than simultaneously, the bottom floral leaves getting well away and displaying a mass of striking colour before the upper bracts are well formed, and the under ones wait for the upper without either drooping or fading, until the plants present a series of perfect bracts of the most gorgeous colouring.—D. T. FISHER.

Shedding of Flowers in Rogieras.—Rogieras deserve all the praise bestowed on them (see p. 102), but the short duration of their flowers—their greatest drawback—should have been pointed out. These plants always remind me of a Laurustinus of a delicate pink colour. Their perfume is also of the sweetest; but unfortunately they neither last long on the plant nor off it. The bunch of flowers also falls to pieces almost as soon as cut. They are pretty for bouquets, but in that case little bunches should be made of the single flowers, in the same way as those of *Quisqualis indica*, a stove climber, with the same fault even more strongly developed, viz., the rapid shedding of its flowers. Treated as I have just mentioned, the Rogieras form charming materials for bouquets. *R. gratissima* is perhaps rather better than *R. amœna*, and forms a welcome addition to the flowering plants of the stove in January and February, a season when stove flowers are somewhat scarce.—D. T. F.

LILY BULBS.—II.

THE following remarks mainly relate to the underground growth of some of the Lilies now cultivated in our gardens; those who desire information respecting their stems, leaves, and flowers, are referred to Mr. J. G. Baker's "Revision of the Genera and Species of Tulipeæ," to which the Lilies belong, published in the "Linnean Society's Journal," vol. xiv., a translation of which, so far as it relates to the present genus *Lilium*, will be found in Vol. VII. of THE GARDEN, 1875, p. 297, accompanied by numerous reduced woodcut figures. In this paper I have also adopted Mr. Baker's arrangement and index to the species of *Lilium* originally published in the "Proceedings of the Royal Horticultural Society." If we could make ourselves perfectly certain as to which of the cultivated Lilies are wild species or types, and which have been produced by seminal variation and hybridism by the Japanese and Dutch cultivators, we should find the bulb structure of Lilies far more characteristic or tangible than at present, although even now the bulbs of Lilies are quite as well suited as aids to classification or arrangement of species as are the corms of Crocuses or Fritillarias. Speaking of Japanese Lily cultivators, it may not be generally known that Lilies and other typical plants (as Iris and *Prœnias*) have been cultivated and improved by particular families in Japan just as are Lilies, Hyacinths, Narcissi, and Tulips at present in Holland, only that this culture has been going on in Japan for generation after generation—one might almost add ages; its origin is lost in legends and mythical obscurity. If one could get at translations of Japanese and Chinese gardening and botanical literature, what a world of discovery in plant improvement would be opened up to us, and how much would some of the botanists, even of our own day, have to regret that they did not give the "inner Celestial" trade-growers more credit for their skill in originating and fixing sports and seminal varieties, if not sexual and vegetative hybrids! In referring to the characters of Lily bulbs, it must be owned that in some cases a great difference is observable between the bulbs of two apparently distinct types or species, but it is impossible to define the difference in words; and this brings me to a point on which I lay great stress, namely, that in figuring any plant the root-growth should in all cases be included in the drawing as worthy of equal consideration with the aboveground development of stem and leaves, especially as it is the foundation whence they spring into life and loveliness; and I feel sure if this practice were adopted in botanical works, many of the now common doubts and misunderstandings as to figures would be prevented. Individual bulbs of any species of Lily, like individual Apples or Pears, are very variable, and those who have many Lily bulbs through their hands are apt to form their ideal of the bulb of any given species from the bulk, taking note of the maximum and minimum variations in a manner of which their ideal bulb is a mean or average. There is, however, a right and a wrong method even in this apparently faultless style of estimating variable characters, for it is possible to imagine what the bulb of any species should be from extreme specimens, and to draw or write about it as though one had actually seen such an actual specimen. This source of error has been carefully guarded against, and although it is not to be expected that we have been fortunate enough to hit everybody's ideal of the bulb-growth of the species figured, still every figure has been carefully made from an actual bulb. Nor did I altogether trust to my own experience in the matter, since the selection of the type specimens in nearly all cases was made for me by Mr. G. F. Wilson, Dr. Wallace, Mr. Horseman, Mr. Bull, Mr. Barr, and other well-known Lily importers and cultivators. Not a scale has been added or sacrificed for artistic purposes, and in most cases the original sketches are reproduced of the natural size.

Sub-genus I.—Eulirion.

Perianth funnel-shaped, horizontal, or slightly drooping, its divisions broadest above the middle, spreading only towards the tip when fully expanded; filaments and style nearly straight.

1. *Lilium cordiflorum*.—The stately *L. cordiflorum* and *L. giganteum* (the latter now pretty generally grown in our gardens) are readily distinguished from all other Lilies by their broadly heart-shaped, Funkia-like leaves, the large thickened

bases of which become somewhat indurated and permanent, forming what may be called a bulb, but one essentially different in texture and general appearance from the bulbs of all other species included in this genus. *L. giganteum* is so similar to the Japanese *L. cordifolium* both in foliage and flower that I follow Mr. Baker in considering them merely forms of the same plant, a

1. *Lilium cordifolium* (Japan and China); half natural size; from cultivated bulb; colour, green and brown. [See p. 131.]

little varied perhaps by different climate, soil, and other conditions mainly dependent on geographical distribution. If all other characters fail, however, the plants are readily distinguished by their bulbs, which differ in several particulars, but like those of many other Lilies, more in general appearance than in describable characters. Mr. Baker describes the bulb of *L. cordifolium* as being "in every

1.* *L. giganteum* (India); one-third natural size; from a cultivated bulb; colour, brownish. [See p. 131.]

respect like that of *L. giganteum*, but smaller, and with thicker, more wrinkled, and less regular scales." I also find the bulbs smaller, and the scales thicker and more succulent, smooth, even glossy when freshly dug. I have not seen dry bulbs, but as a rule the more fleshy and succulent bulbs are when fresh, the more wrinkled they become when dried. Both are deciduous in November, and the

bulbs of *L. cordifolium* are then plump and glossy, the size of a duck's egg or larger, and formed of five or six (in very large bulbs more) thick, rounded, whitish scales, which become green suffused with brown if exposed to the light and air. These scales are semi-circular or lunate in section, the cut part or interior being formed of rich green cellular tissue, among which are embedded numerous longitudinal fibres, which terminate suddenly at the articulation between the petioles of the decayed leaves and the apex of the bulb scales, leaving a clean scar, as shown in our engraving (see fig. 1).

L. giganteum has larger and more elongated scales of a rough leathery texture, and often fibrous externally, and the articulation between the petiole and the top of the scale is not a clean one, as in *L. cordifolium*, but each scale is terminated by an irregular tuft of fibres, as shown in our illustration (see fig. 1*). The bulbs of both these plants have a caespitose or clustered habit of growth, as in many other species, but their extremely thick scales, formed of green cellular tissue and longitudinal fibres enclosed in an indurated or leathery, glossy or fibrous coat, serve to distinguish them at a glance from their allies.

[*L. CORDIFOLIUM*, Thunb.—Sub-species (1) *Cordifolium* proper.—Japan; figured in Sieb. & Zucc., Fl. Jap., fasc. 3, t. 13, fig. 2, and t. 14; "Flore des Serres," t. 216. Sub-species (2) *Giganteum*.—Central and Eastern Himalayas, from 5000 ft. to 10,000 ft.; figured in Wall. Tent. Fl. Nep., t. 12, 13; Bot. Mag., t. 4673; "Flore des Serres," t. 771, 772; "Belgique Horticole," iii., t. 21.]

2. *L. longiflorum*.—This is a highly variable plant in aboveground growth and flower, but the bulb structure is remarkably constant in form and colour, the main points of

2. *L. longiflorum* (Japan); one-third natural size; cultivated bulbs; colour, yellow.

NOTE.—The bulb of this plant has often the flattened top and restricted base of *L. japonicum* Brownii, but is always white or clear yellow, never purple-stained.

difference being the relative size and thickness of the scales and bulbs. The bulb structure of this plant closely resembles that of the common white *L. candidum*, being of the typical ovoid type, with lance-shaped imbricating scales of a white colour changing to pale yellow on exposure. Our illustration shows the contour of these better than any description could possibly do (see fig. 2). The old flowering bulb of July, 1875, which yet bears the remains of the flower-stem, has, as will be seen, been succeeded by a new bulb, and this at the time our sketch was made in November, 1876, had already commenced to throw up its growth or flower-stem. This is the earliest of all Lilies in making its growth, if we except *L. candidum*, in which the young scale leaves of autumn succeed the foliage of spring so quickly, that practically it may be considered an evergreen species. The Lily now grown in gardens under the name of *L. neilgherrense*—a very variable one—is by Mr. Baker held to be a form of *L. longiflorum*, and will be so considered here, although differing in its late-blooming habits and curious method of self-increase, apart altogether from its larger flowers, different geographical distribution, and occasional change of colour. Its bulb-growth is very similar to

that of *L. longiflorum*, but the scales are fewer and thicker or more fleshy, and the entire bulb is generally more pointed, the scales being tinged with purple, as in its ally *L. Wallichianum*, and not uniformly yellow, as in the forms of *L. longiflorum* proper. Mr. Elwes has pointed out that the bulbs of "this species have the merit of increasing rapidly in size, and multiplying both by offsets and by the long horizontal subterranean stems, which are so remarkable in some specimens. I have seen them come up more than 1 ft. from the bulb, and even

2*. *L. neilgherrense* (India, Neilgherry Hills); one-half natural size: (a) cultivated flowering bulb; (b) cultivated subterranean stem-producing bulb, the stem bearing bulbils at the nodes; (c) section of scale; colour, yellow or yellowish white, sometimes tinged with purple or brown.

descend to the bottom of the pot and come out through the drain hole." Mr. Barr kindly allowed me to turn out and examine several of his large pots of this species, in each of which ten or twelve bulbs had been placed, and about half of these bulbs had thrown up flower-stems, and had also increased in size. Some of the bulbs, however, and, as it seemed to me, the weaker ones, had produced underground stems which had coiled themselves around the sides of the pots, and bore bold bulbs at intervals, as shown in my sketch (see fig. 4); some of these subterranean stolons were fully 2 ft. in length, each having from five to six bulblets, according to length or number of nodes, and here and there a few root-fibres. These fibres, however, were not so strong as the whorl of roots near the base of the flowering stems, and the bulbs which produced these bulblet-bearing stolons, had not increased in size by the increment of new growth; indeed, in some cases where the stoloniferous bulbs were larger than usual, they seemed to have, as a rule, exhausted the parent bulb. Mr. James McIntosh, of Oatlands, Weybridge, planted a bulb of this plant in his garden in May, 1876, which produced a flower-stem 4 ft. 7 in. in height, bearing a solitary flower fully 7 in. across the funnel-shaped mouth. The beautiful *L. philippinense* (see Bot. Mag., t. 6250), a slender, grassy-leaved species, introduced from the Philippines a year or two ago by Messrs. Veitch & Son, has the bulb structure of *L. longiflorum*, which it also resembles in flower; indeed, botanically it is interesting, as showing the extreme development of the peculiarities that mark the *Elvirion* group.

[*L. LONGIFLORUM*, Thunb.—Sub-species (1) *Longiflorum* proper.—Japan and China; figured in Bot. Reg., t. 560; "Flore des Serres," t. 270; Lodd., Bot. Cab., t. 985; Bury Hexand., t. 8. Var. I. *Eximium*.—Japan. *L. eximium*, Court., Spae Mon., p. 14; "Flore des Serres,"

t. 283-4. Syn., *L. Jama-juri*, Siebold & De Vriese, "Tainbow Flora," vol. i., p. 319, t. II. *L. longiflorum* Takesima, Duchartre Obs., p. 38. *L. longiflorum* Liu-Kiu, Siebold. Sub-species (2) *Neilgherrense*.—Neilgherries; figured in Wight, "Icones," t. 2031. Syns., *L. tubiflorum*, Wight, "Icones," t. 2033-4; *L. Wallichianum*, Wight, "Icones," t. 2035, not Schultes; *L. neilgherrenum*, Lemaire Ill. Hort. x, t. 353; *L. Metzii*, Stendel.

3. *L. Wallichianum*.—The bulbs of this plant are in form like those of *L. neilgherrense*, the main difference being in the remarkably thin margins to the scales, and the dried and exposed bulbs acquire a deep purplish-red colour, quite distinct from anything I have seen in any of the *L. longiflorum* type, the scales having thin, scarious margins. This exhibition of colour in the bulb would seem to imply that *L. Wallichianum* is more closely allied to *L. japonicum* or *L. Browni* than to its ally *L. neilgherrense*, although some forms of the latter plant are said to show pink or rose colour in the flower; and that this tint is present even in plants of the white and buff-coloured varieties, is shown by the purplish-brown stem, since this is the result of red colouring matter having blended with the green colour; but, as we have before stated, vagaries of colour in the bulb are so unaccountable and perplexing, that no reliance can be placed on it specifically, and even in the case of individuals, there is apparently no relation between the colour of the bulb and that of the flower. The flowering bulb from which our engraving was made was a large and developed one of a deep purplish-red or port-wine colour, but the most peculiar characteristic seemed to be

3. *L. Wallichianum* (Central Himalayas); natural size; from cultivated bulb colour, dull crimson, with membranous scale margins.

the scarious, membranous margins to the closely imbricated scales. The individual bulb kindly sent to us by Mr. Horseman, of the Colchester New Plant and Bulb Company, is interesting as having supplied the stately inflorescence from which Mr. W. H. Fitch has prepared a beautiful water-colour sketch, hereafter to be published in Mr. H. J. Elwes' work on the genus *Lilium*. Our illustration is exactly natural size, literally scale for scale, but, as a rule, the bulbs of this species do not attain so large a size, except when grown under the best cultural conditions. *L. Wallichianum*, although introduced to Glasnevin many years ago by Major Madden, never seems to have attained anything like its native vigour in our gardens, and its extremely late-flowering habit is against its ever taking a place among the hardy species, although it may by a suitable course of culture be made to bloom earlier. "The formation of the tall, erect stem, having its flower-buds concealed at the top, suggests the idea that it is naturally destined to find its way upwards among low-growing herbage and shrubs into the full light of day, to mature in sunshine its flowers and seed-pods. Such, at any rate, is the account given us by our Indian correspondent of the beautiful and stately *L. Wallichianum*, whose noble, large white flowers may be noticed miles away from the opposite bank of a deep Himalayan valley, growing some 10 ft. or 12 ft. in height, yet only just peering out above the surrounding brushwood and jungle." The success already attained by Mr. James McIntosh in growing its ally, *L. neilgherrense*, in his *Rhododendron* beds at

Oatlands, Weybridge, seems to show that the above conditions are suitable to both plants. A correspondent, writing to Mr. Barr from Mussouree, thus describes the climatic conditions under which *L. Wallichianum* is sometimes found in its Indian habitats:—"Flowers in August, but more usually in September. It is a hardy plant, and here defies both heat and cold. I find it growing at an elevation of 5500 ft. on the open grassy hills, with a slope sometimes of 45, not under forest shelter but in open tracks, the soil full of bits of limestone pebbles, and the matrix composed of lime, clay, and vegetable mould. From the great slope of the hill it is thoroughly free from surplus water, the temperature of the summer sun being from 120 to 130. From June to the end of September it grows in a perfect deluge, and often is enshrouded in mist for days together, that being our rainy season. From September to December it gradually dies down in a fine warm temperature by day, with hoar-frost at night in November. Little rain falls during these months. Sometimes there is but little snow in winter, say 3 in. to 4 in. with hard frost; at other times the snow lies over them 2 ft. in depth, but this is unusual. The bulbs lie at a depth of 6 in. to 9 in., and are uninjured. The plant seldom or never produces seed, but is propagated by suckers or by bulblets from some part of a long root [? underground stem, as in its ally, *L. neilgherrense*], so that the flowering plants are surrounded by numerous young ones of various ages." Another correspondent thus writes:—"this *Wallichianum* is a magnificent Lily; I have seen it in the Himalayas 8 ft. high."

[*L. WALLICHIANUM*, Schultes fil.—Central Himalayas, 3000 ft. to 1000 ft.; figured in Bot. Mag., t. 4561; Lindl. & Paxt., Fl. Gard. 1850, 120; Lemaire, Jard. Fleur., t. 105, 6; "Flore des Serres," t. 612, Syn., *L. Batisua*, Ham. mss. *L. japonicum*, D. Don, not of Thunb. *L. longiflorum*, Wall. Tent. Fl. Nep., t. 29, not of Thunb.]

4. *L. japonicum*.—This is another variable plant, represented in gardens by *L. (japonicum) Browni*, *L. Krameri*, and their forms, all of which are, however, too nearly allied to be separated otherwise

1. *L. japonicum* Browni (Japan); natural size; from full-sized imported bulb; colour, yellowish white, much tinged and dotted with purple.

NOTE.—*L. longiflorum* often has bulbs exactly this size and form, but either pure white or clear yellow, never, or very rarely, suffused or dotted with purple.

than under the above specific heading. *L. Krameri* has rather a small bulb, say the size of a large Walnut, and such bulbs generally throw flowers; indeed, plump bulbs but little larger than a Cobnut frequently produce a solitary bloom. The bulb structure and growth of *L. Krameri* is almost identical with that of *L. longiflorum*, and this seems the best argument against this plant being a hybrid between *L. speciosum* and *L. japonicum*, since there are none of the characters of *L. speciosum* in it at all, and it had best be considered as a well-formed, delicately-coloured *L. japonicum*; or if a hybrid, then *L. longiflorum* and *L. Browni* must have been the parents. The colour of the *L. longiflorum*-like bulb is white shaded with yellow and sometimes suffused with brown. The bulbs of the robust-growing *L. Browni* are peculiar in shape, being somewhat like a Tangerine Orange, oblate in form, the base being curiously constricted, as shown in our sketch, made from a fine bulb kindly sent by Dr. Wallace. The colour of the scales in the specimen sent was white much suffused and dotted with purple, but Mr. Barr tells me that in some soils the bulbs are yellowish-white, and that they do not turn purple on exposure, although the yellow deepens in tone considerably. Dr. Wallace, in one of his papers to THE GARDEN, has pointed out that the bulbs of this noble Lily are peculiarly liable to decay at the base,

and after carefully examining the bulbs of this plant, I believe this is due to their singular structure, the scales being very much hollowed out at the base, and as these become closely imbricated cap-fashion, the moisture, which finds an entrance at the flat apex of the bulbs where the scales are pointed and looser, is prevented from effecting its escape below, and so rots the bulb. As this particular kind is so liable to suffer, it would be well to adopt the Japanese method of planting the bulbs sideways to prevent the lodgment of superfluous moisture. A glance at our figure of the bulbs of *L. longiflorum* shows the bulb of that plant slightly different in shape to that of the *L. Browni* form of *L. japonicum*, but the two types slide into each other almost imperceptibly through the *L. longiflorum* like bulbs of *L. Krameri*.

[*L. JAPONICUM*, Thunberg, Japan, and Korean Archipelago.—Var. 1. *Japonicum* proper; figured in Bot. Mag., t. 1591; Lodd., Bot. Cab., t. 438; Reich., Exot., t. 88. Syn., *L. odorum*, Planch., "Flore des Serres," t. 876, 7. Var. 2.—*Browni*.—Japan; figured in Mielle, "Flore des Serres," t. 47. Syn., *L. japonicum*, Bury Hexand., t. 2.]

5. *L. nepalense*.—I have been unable to obtain bulbs of this newly-introduced Indian Lily.

[*L. NEPALENSE*, D. Don.—Temperate Central Himalayas. This plant is now in cultivation. Var. 1. *Nepalense* proper; figured in Wall., Pl. Asiat. Rar., t. 291. Var. 2. *Trieps*.—Central Himalayas; not known in cultivation; figured in Klotzsch, Reise Wald., t. 83. Var. 3. *Nanum*.—Central Himalayas; not known in cultivation. *L. nanum*, Klotzsch.]

6. *L. candidum*.—This is doubtless the best known of all Lilies, forming clumps of bright yellow bulbs, which differ from those of *L. longiflorum* mainly in having some of their broader scales terminated by leaves. It is the only evergreen Lily we have, and its golden-margined and striped-foliaged varieties are mainly valuable for winter decoration on this account. In good, rich, well-drained soils this Lily increases itself rapidly by offsets and scale-bulbs, but it very rarely bears fertile seeds. It is one of the parents of *L. testaceum*, the bright scarlet Turk's-cap (*L. chalcedonicum*) being the other, and seeing that it is so

6. *L. candidum* (Southern Europe); one-third natural size; cultivated bulb; scales of do. natural size; section of do. and reduced figure of bulb and winter foliage; colour, yellowish white.

robust and floriferous, one can only hope that Mr. Frank Miles and others who have taken up the cross-breeding of Lilies, will be successful in improving or varying the forms and colours of some of these free-growing old kinds. Our engraving shows reduced views of the bulbs and scales in different positions. It is very rare, however, to find a solitary bulb of this species, as, indeed, of any other perfectly hardy and vigorous-growing Lily, as these, if planted in rich, deep soils, form large clumps, some of the old flowering bulbs breaking up into four or five bulbs, but all fused together on the old root-stock. I have seen clumps of the common white and orange Lilies dug up fully 2 ft. in diameter, these being formed of flowering bulbs, old clustered masses of scales and offsets of all sizes.

[*L. CANDIDUM*, Linn. Sub-species (1) *Candidum* proper.—South Europe; figured in Bot. Mag., t. 278; Redouté, Lil., t. 199; "Flore des Serres," t. 735; Bury Hexand., t. 38; Reich., Fl. Germ., 445. Var. *Striatum* Hort.; figured in "Flore des Serres," t. 735. Sub-species (2) *Peregrinum*.—Never seen in a wild state, and now apparently lost from cultivation in this country; figured in Miller; Sweet, Brit. Flow. Gard., ser. 2, t. 367; Hayne, Arzne, 8, t. 27.]

7. *L. Washingtonianum*.—This beautiful Lily is found on the Sierra Nevada at an altitude of 5000 ft. to 6000 ft., and during the winter months its bulbs are frequently covered with 15 ft. to 20 ft. of snow. Mr. Baker describes its bulbs as being "oblique, white, sub-rhizomatous, with small, lance-shaped scales," and judging from about 1200 imported bulbs of this plant in splendid condition which I saw at Mr. Ball's in November last, that description is accurate. The oblique and elongated habit of growth was

7. *L. Washingtonianum* (America, Sierra Nevada); one-third natural size; imported bulbs. The smaller figure one-fifth natural size.

well shown in these bulbs, two forms of which are represented in the engravings, one of a full-sized old bulb, these being 6 in. to 8 in. in length. Even the plump, short, young, imported bulbs have an oblique appearance, as in the smaller figure, but Mr. Barr tells me that this habit of growth becomes changed under our garden culture, where the bulbs assume the ordinary ovoid type of growth. Messrs. Hooper & Co. had a strong-flowering clump of this species in their nursery at Twickenham a year or two ago, where, planted in marl or gravel in a sheltered position, it flowered freely. The Lily now grown in gardens as *L. purpureum* has a rounder, plumper bulb of a yellowish-white colour shaded with brown, and its habitat is different to that of *L. Washingtonianum* proper, since it is found at a lower altitude in the Yosemite Valley "in a climate of perpetual spring." It is by some called *L. Washingtonianum*, "Eel River variety," since it is tolerably abundant in the moist valley of that stream; its umbel-like style of flowering may serve to distinguish it from the type. The bulb-growth, although very distinct in imported specimens, cannot be trusted as a distinguishing character, since cultivated bulbs of *L. Washingtonianum* proper are nearly identical with those of *L. purpureum*, and even the points of difference between the native bulbs of both plants are not more than can readily be accounted for as being due to difference of soil and climate. *L. Humboldtii*, although very different to *L. Washingtonianum* in its flower, has an ovoid, oblique bulb, very similar in shape to the smaller figure (fig. 7), and it is very rare that they are found with anything more nearly approaching the rhizomatous habits of *L. Washingtonianum*.

[*L. WASHINGTONIANUM*, Kellogg.—California; figured in Gard. Chron., 1871, t. 142; "Regel Gartenflora," t. 170; "Flore des Serres," t. 1975-6. Syn., *L. Bartrami*, Nuttall, Herb.]

Sub-genus 2.—*Archelirion*.

Perianth broadly bell-shaped, horizontal or slightly drooping, its divisions ovate or lanceolate, not distinctly clawed, spreading widely from below the middle when fully expanded; style declinate, and stamens much curved.

8. *L. tigrinum*.—The bulbs of this variable plant are, according to Mr. Baker, "perennial, globose with oblong, lance-shaped, acute scales." The specimen selected for me by the Colchester Bulb Company was, as shown in our engraving (8, fig. 1) as large as an Orange, and of a similar oblate contour, the scales of each being very few in comparison with such bulbs as those of *L. bulbiferum* (*L. Thunbergianum*), and very much

broader. We have a small group of so-called species with this type of bulb-growth, such as *L. Leichtlini*, *L. Maximowiczii*. *L. tigrinum* sinense is, so far as I have seen, the largest and most vigorous in bulb-growth, after which we descend to the smaller but similarly shaped bulbs of *L. Maximowiczii* (syn., *L. tigrinum jucundum*), and the still smaller ones of *L. Leichtlini*, which vary from the size of a Filbert to that of a large Walnut, but all being whitish in colour, and having an oblate contour, with broad scales. The last-named plant, apart from its pale yellow flowers, has a singular spreading habit of growth, the flower-stems having a running habit, often coming up 1 ft. or more from where the bulb was planted, and on this account the plant cannot be grown in a pot with success, since the stems run to the sides of the pot, and so become stunted and otherwise injured. The plants we have enumerated above, together with *L. tigrinum majus*, and *L. t. splendens*, are clearly shown to be related by their bulb structure; and Mr. Baker, in describing *L. Leichtlini* as a species on the authority of Dr. Hooker, remarks, that it flowers in July in gardens at the same time as *L. tigrinum*. It seems to me most probable that this plant is a yellow seedling variety, raised in Japanese gardens; nor is this change of colour remarkable, since we have one or two varieties of the crimson-scarlet Chinese or Mongolian *L. concolor* distinguished by their yellow flowers.

[*L. TIGRINUM*, Gawl.—Japan and China; figured in Bot. Mag., t. 1237; Redouté, Lil., t. 395 and 475. Syn., *L. speciosum*, Andrews, Bot. Rep., t. 585, not Thunberg. Var. 1. *Fortunei*, Hort. Var. 2. *Splendens*, Hort.; figured in "Flore des Serres," t. 1931-2; Floral Mag., t. 509. Syn., *L. tigrinum Leopoldi*, Hort. Var. 3. *Lishmanni*, Moore, "Florist," 1873, p. 13 with figure.]

9. *L. speciosum*.—This plant has a bulb the size of a large St Michael Orange, globose, brown or brownish-red as a rule, sometimes white or yellowish, the scales being thick, fleshy, broad, lance-shaped, and closely imbricated in newly dug bulbs, but with loose or open scales in dried imported specimens. Our figure shows a full-sized flowering bulb with open scales, and a reduced sketch of a freshly dug specimen, in which the curved fleshy scales are closely imbricate. The bulbs of this plant are extremely variable in colour, varying from white to deep purplish-crimson, especially in light porous soils. This plant has been largely propagated from seeds by the Dutch growers, and formerly by Mr. Groom, Messrs. Henderson & Son, and other bulb cultivators in this country; hence we find numerous minor differences in growth and colour of the flowers.

[*L. SPECIOSUM*, Thunberg.—Japan; figured in Bot. Reg., t. 2000; Sieb. & Zucc., Fl. Jap., fasc. 3, t. 12 and t. 13, fig. 1. *L. speciosum*, var. *Kaempferi*, Bot. Mag., t. 3785; "Flore des Serres," t. 276-7. Syn., *L. lancifolium*, Hort., not Thunberg. Stems purplish-brown. Var. 1. *Rubrum*, Masters in Gard. Chron., 1872, p. 1522, Var. 2. *Album*, Masters l.c. Stems green. Var. 3. *Speciosum* proper. Var. 4. *Roseum*, Masters l.c. Syn. *L. speciosum*, Paxt. Mag. v., t. 1. Var. 5. *Punctatum*, Lom., "Flore des Serres," under t. 277. Brux., Feb., 1834. *L. speciosum vestale*, Hort. *L. eximium*, Hort.]

10. *L. auratum*.—The bulbs of this variable species are as large as, and similar in colour, shape, and structure to, those of the last-named plant, a fact which goes some way to prove their near alliance, especially when we find this more fully proved by the fact of these two species having been hybridized, the beautiful *L. Parkmani* being the offspring of these two species, as also was an earlier hybrid called *Purity*, and certificated some years ago by the Royal Horticultural Society at South Kensington.

[*L. AURATUM*, Lindley.—Japan. Var. 1. *Auratum* proper; 1867, p. 294.—figured in Bot. Mag., t. 5338; "Flore des Serres," t. 1528, 1531; Ill. Hort., ix., t. 338; Revue Hort., 1867, t. 371. Syn., *L. Dexteri*, Hovey. Var. 2. *L. Wittei*, figured in Suringar in *L. Koch Wochens.*]

Sub-genus 3.—*Isolirion*.

Perianth broadly bell-shaped, quite erect, its divisions oblong-lanceolate, broadest about the middle, spreading in the upper half or third when fully expanded; stamens divergent on all sides from the centre of the flower.

11. *L. philadelphicum*.—Mr. Baker describes the bulbs of this plant as "small, annual, stoloniferous; scales fragile, thick, nearly club-shaped," and I have elsewhere found them described as being produced in a rhizomatous manner in their Canadian and Carolinian habitats; my figure was made from a specimen selected from a small importation of fifty or one hundred roots which I saw at Mr. Barr's, and represents a full-sized bulb, but I saw no traces of rhizomatous growth; but it is possible they had been broken up before transit, previous to their having been counted and invoiced. The bulbs vary in size from that of a Cobnut to a large Walnut; but large and small

alike bore traces of the old flowering stems. I find the scales thick and club-shaped, as described by Mr. Baker, while the fragility to which he alludes is due to most of the scales being jointed about the middle, so that the upper half is apt to be snapped off if the bulbs be not carefully handled. As shown in our sketch, the scales in the new-growing point of the bulbs bear a few slender, flexuose leaflets, but this is not always the case. The bulbs of this Lily are very much like those of the Californian *Fritillaria recurva*, which also has jointed or articulate scales, but a much thicker root-stock or depressed stem than our present plant. Some American authors have described this plant as having stoloniferous or rhizomatous bulbs, but I have seen no evidence of this being the case; it is, however, a point on which we require fuller evidence from those who have collected the plants in its native habitats.

[*L. PHILADELPHICUM*, Linnaeus.—Canada and Northern United States; figured in Bot. Mag., t. 519; Reloué, Lil., t. 101; Lodd., Bot. Cab., t. 976; Bot. Reg., t. 594. *L. andinum*, Nuttall. *L. umbellatum*, Parsh.]

12. *L. medeoloides*, A. Gray.—This Japanese plant is said to be intermediate between *L. avenaceum* and *L. Martagon*, "but is distinguished by its erect flowers, falcate (not revolute) segments, and short stamens and pistil." It is not known in cultivation.

13. *L. Catesbæi*.—Mr. H. J. Elwes thus describes the bulb of his plant in a former issue of THE GARDEN:—"The bulb of *L. Catesbæi* is very peculiar and unmistakable. It is figured, though not very well, in the 'Botanical Magazine,' t. 259, and may be easily recognized by its small-sized, thin, pointed, white scales, some of which are in weak bulbs prolonged into a narrow leaf. It has been out of cultivation for a long time, I believe, the plant grown as *L. Catesbæi* in some nurseries being the one figured in the 'Botanical Magazine,' t. 872, as *L. pennsylvanicum*, but really a Siberian Lily, and, as I think, differs from the true *L. davuricum* in the form of the bulb, which is very remarkable in both these species." Mr. Baker

says, "Bulb exactly like that of *L. philadelphicum*," but, with Mr. Elwes, I must hold that fresh bulbs are very distinct. I saw a small parcel of thirty or forty bulbs at Mr. Barr's grounds one morning, and the very fact that these two species were so distinct in bulb structure while their aboveground growth is in some points very similar, led to the preparation of this series of sketches and notes on Lily bulbs. *L. oxypetalum* is the only Lily I know which has similar bulbs, but the scales of that plant are pointed, whereas nearly all the smooth white scales of *L. Catesbæi* bear a scar at its apex where a leaf has fallen away, nearly all the young scales being terminated by slender, sinuate leaves, as shown in our illustrations on p. 137.

[*L. CATESBÆI*, Walters.—United States; figured in Bot. Mag., t. 259; Lodd. Bot. Cab., t. 807; Sweet, Brit. Flow. Gard., ser. 2, t. 185. Syn. *L. spectabile*, Salisb. Parad., t. 5, not Link.; *L. carolinianum*, Catesby, not Michaux.]

14. *L. bulbiferum*.—An extremely variable plant, the bulbs of the different forms varying in size from that of a small Walnut, as in *L. alutaceum* (a dwarf, apricot-coloured species, which bears its erect flowers on stems 1 in. or 2 in. in height) to large, plump bulbs the size of a large Orange, and having very closely imbricated scales, as in *L. Thunbergianum splendens* and in *L. umbellatum maculatum* of gardens. Mr. Baker describes the bulbs as "ovoid-perennial, scales few, broad, and acute." Our illustrations give some idea of the variability of bulb-growth observable in the varieties or forms of this species. The bulb of *L. umbel-*

latum maculatum sent us from Colchester was fully 4 in. in diameter, the numerous fleshy, broadly lance-shaped, purplish scales, being closely adpressed to each other so as to give a remarkably solid appearance to the whole bulb. Mr. Baker describes this as a "luxuriant garden form of *L. davuricum*." With it came the smaller bulb of *L. croceum*, with broader and fewer pinky-white scales, and these are more constricted than in the last. *L. Thunbergianum splendens* has bulbs similar to those of *L. umbellatum*, but smaller, with purplish-tinted, closely-adpressed scales, and the bulbs are apt to assume the flat-topped contour so characteristic of *L. Browni* and *L. longiflorum*. *L. davuricum* proper is rather peculiar in its bulb-growth, and we figure two of the most distinct of its forms. One type has ovoid bulbs composed of narrow, lance-shaped, fleshy scales, these last being extremely brittle at the base, indeed, the old flowering bulbs are apt to fall to pieces unless handled very gently. This form, as shown in our sketch, is very proliiferous, numerous little bulblets being formed at the base of the bulbs, and among the wig-like mass of roots at the base of the bulb. It has long been grown by the Dutch florists, by whom this proliiferous habit of scale propagation has doubtless been fostered. Another form I saw in Mr. Bull's collection, although identical with the last in aboveground growth, has a more globular bulb composed of shorter, blunter, and more fleshy scales, many of the latter being once, and some even twice, jointed as shown in our sketch. Mr. Elwes tells me he received

similar bulbs from Maximowicz, and that he is instituting further inquiries respecting them. Another distinct Lily referred under the heading of *L. bulbiferum* by Mr. Baker is *L. Wilson* (of Leichtlin), for a bulb of which I am indebted to Mr. G. F. Wilson himself. The largest bulb which could be found at the time is here figured, and resembles that of *L. bulbiferum* in size and contour, being composed of thick, closely adpressed, pinkish scales. Herr Max Leichtlin, who is the authority for this species, suggests that it may possibly be a hybrid between *L. elegans* (*L. Thunbergianum*) and *L. speciosum*. *L. bulbiferum* has long been grown in European

2. (1.) *L. tigrinum sinense* (China and Japan); natural size; large cultivated bulb. (2.) *L. Leichtlini*, natural size. (3.) Small bulb of the same; colour, yellowish white. [See p. 135.]

gardens, and, like many other species, has become differentiated by seminal reproduction.

[*L. BULBIFERUM*, Linn.—Sub-species 1. *Bulbiferum* proper—Austria, Sweden; figured in Jack Austr., t. 226; Bot. Mag., t. 36; Redouté, Lil., t. 210; Reich., Germ., t. 454; Regel Gartenflora, 1872, p. 231, with woodcut of bulb. Sub-species 2. *Croceum*, Chaix, —France, Switzerland, and North Italy; figured in Lodd., Cab., t. 784; Reich., Germ., t. 454. Sub-species 3. *Davuricum* Gawl.—Through Siberia; figured in "Regel Gartenflora," t. 740, and 1871, p. 231, with woodcut of bulb. Syn., *L. pennsylvanicum*, Gawl., Bot. Mag., t. 872; *L. spectabile*, Link; Reich., Icon. Exot., t. 30; "Regel Gartenflora," t. 349; *L. Baschianum*, Lodd., Bot. Cab., t. 1628. Sub-species 4. *Thunbergianum*, Schultes fil.—Japan. Var. 1. *Thunbergianum* proper; figured in Lindl. Bot. Reg., 1839, t. 38; Maud. Bot., t. 158. Syn., *L. aurantiacum*, Paxt. Mag., 6, p. 127, with a figure. Var. 2. *Brevifolium*, Baker & Dyer in Gard. Chron., 1872, p. 1356. Var. 3. *Bicolor*, Moore in Flor. Mag., t. 104. Syn., *L. pictum*, Hort. Sieb.; *L. aurantiacum*, Hort. Krelage. Var. 4. *Wilsoni*, Leichtlin. Syn., *L. pardinum*, Moore, Flor. and Pom., 1861, p. 121, with a plate. Var. 5. *Alutaceum*, Baker & Dyer l.c. Syn., *L. Thunbergianum aureum nigro-maculatum*, "Flora des Serres," t. 1627. Var. 6. *Armeniacum*, Baker & Dyer. Var. 7. *Citrinum*, Hort. Wilson. Var. 8. *Sanguineum*. Syn., *L. sanguineum*, Bot. Reg., 32, t. 50; *L. biligulatum*, Hort.; *L. lateritium*, Hort. Var. 9. *Atro-sanguineum*, Baker & Dyer l.c. Syn., *L. hematocroium*, Lem. Ill. Hort., t. 503.

Var. 10. *Fulgens*, figured in Morren, Spæe Mon., 29; Lemaire, Ill. Hort., t. 422. Syn., *L. venustum*, Kunth, "Flora des Serres," t. 657; *L. fulgens* var. *staminosum*, Lemaire, Ill. Hort., t. 1422, is a double-flowered form.]

11. *L. philadelphicum* (Canada and N. United States); natural size; from an imported bulb; colour, white or yellowish. [See p. 135.]

15. *L. lancifolium*, Thunberg.—Not in cultivation, possibly a variety of the last.

16. *L. pulchellum*.—This is now regarded as a form of the next species.

[*L. PULCHELLUM*, Fisch. & Meyer.—East Siberia; figured in Regel Gartenf., t. 284, fig. 2; Revue Hort., 1862, p. 131, with a figure.]

13. *L. Catesbaei* (United States); from imported bulbs; colour, white.

17. *L. concolor*.—*L. concolor* may be taken as the type of a group of Siberian, Chinese, and Japanese Lilies, having very distinct bulbs; and Mr. Baker's description of the bulbs of *L. concolor* will almost include all of them. These are small yellow or scarlet-flowered species of slender habit, the most distinct being *L. callosum*, *L. tenuifolium*, and *L. concolor*, with its distinct forms, as *L. sinicum*, with solitary, broad, scaled-bulbs;

L. parthenseion, with caespitose or clustered bulbs, *L. coridion*, also with caespitose bulbs, but distinguished by its scarlet flowers; *L. pulchellum*, bulb ovoid, scarcely 1 in. long (red, black-dotted flowers), and a yellow-flowered variety, is cultivated in Japan, being found wild on stony hills in Chinese Mongolia. All the bulbs of this section have few, but thick wax-like scales, which are not only as a rule closely imbricate, but fold closely round each other in a more or less convolute manner. The only Lily which has bulbs

14. *L. divuricum* (Europe, Dahuria); natural size; cultivated bulb; colour, whitish. [See p. 136.]

anything like these three types is the Indian *L. polyphyllum*, except that Mr. Elwes remarks, that he has seen somewhat similar bulbs (presumably those of a species of Lily) from California. *L. concolor* has ovoid bulbs, composed of eight or ten fleshy-white constricted or fiddle-shaped scales as shown in the sketch. *L. callosum* has similar bulbs, but inclined to be oblate in form—that is, not so much pointed; and there are in the bulbs of this plant more scales, these being constricted, as in the last-named type. *L. tenuifolium* has

14. *L. davuricum* (Europe, Dahuria); natural size; from a large imported bulb; colour, white. [See p. 138.]

extremely variable bulbs, some being ovoid, the size of a large Walnut and composed of eight or ten scales; others being quite slender formed, of two or three narrow elongated scales. A yellow variety of *L. concolor* (*L. concolor* var. *luteum*) is figured at t. 885 of the "Gartenflora" for December, 1876, and may possibly be identical with the yellow variety of *L. pulchellum* alluded to as being wild in Mongolia.

[*L. CONCOLOR*, Salisb.—China and Japan. Var. 1. *Concolor* proper.—China; figured in Salisb. Parad., t. 47; Bot. Mag., t. 1165. Var. 2. *Sinicum*, Lindl.—China; figured in Paxt. Flow. Gard., vol. ii, misc. t. 193; Ill. Hort., t. 100; "Flora des Serres," t. 1206

Bot. Mag., t. 6005. Var. 3. *Coridion*, Sieb. & De Vriese. Figured in Sieb. & De Vr., "Tainbow Flora," v. ii., p. 341, with a figure. Var. 4. *Partheneion*, Sieb. & De Vriese.] F. W. B.

COMMON LILAC MADE WHITE BY FORCING.

PERHAPS there is no other flower so fragrant during midwinter as the Lilac when forced in darkness; and as it is within the reach of all who are in possession of a Mushroom-house or heated shed, we have often wondered why those who appreciate sweet-scented flowers should not have paid more attention than hitherto to this admirable method of Lilac forcing. It is true that when plants are subjected to a high temperature in a dark house or shed, they are afterwards useless, but the yield in beautiful flowers would trebly compensate for the original value of the plants. Lilac flowers produced in this way are held in such esteem with us that we have had a small house specially fitted up for obtaining them; we have, therefore, little difficulty at any time, with two or three weeks' notice, in getting a basketful of these truly beautiful snow-white flowers, two or three sprays of which will perfume the air of a room for days. Our house is merely an old shed with a closely-thatched roof; but we have taken care to have efficient heating power. We have also managed to effect the same purpose with success by partitioning off heated structures in out-of-the-way corners, varying them according to circumstances connected with the atmospheric conditions of the houses in which the forcing is being carried out. Our practice is as follows:—In autumn we examine our shrubby borders, and endeavour, as far as possible, to select the requisite number of plants from places where overcrowding is most apparent, and where a thinning out is most likely to do good; we choose bushes which are conspicuous for prominent, well-developed buds, and these we partially cut round some time previous to their being lifted, in order to prepare them for early work. It must be borne in mind that unless the buds are prominent, and the flowers present in embryo, any attempt at forcing will be futile. We have tried young plants from the nursery more than once, but have always failed, young trees seeming to lack sufficient stamina to undergo such an ordeal of forcing in the absence of light. To our mind

nothing can go further to exemplify—if exemplification be needed—the quantity of stored-up nutriment in deciduous trees, than to see one of those glorious bushes literally covered with wreath after wreath of flower, without any indication of growth in the shape of young shoots or leaves; for if forcing be conducted slow enough to allow of young shoots being pushed, or even simultaneous action of leaf and flower, the latter will be of little value. It will thus be seen that success lies in rapidity of action, provided the material in hand be in all respects suitable for such forcing. As the season advances, the progress of vegetation renders forcing less risky. From the beginning of January a fortnight or three weeks at the most will be sufficient time after the plants are introduced into heat till the flowers are ready for cutting. The syringe may be freely used at first, and heat gradually applied according to the progress made, but a dry atmosphere must be maintained as the flowers expand or they will damp off in a few hours, and when damping off sets in no treatment seems powerful enough to counteract the evil.

We have a nursery of the variety known as Charles the Tenth, in an open favourable situation; from the plants in this all suckers are removed as they appear during the summer, and they are lifted annually so as to prepare them for this system of forcing. When we think these young trees are fit for forcing, we anticipate results in proportion—perhaps in excess of our labour. An error too commonly made is to mistake the Persian Lilac for the common one; but the Persian will not submit to forcing in darkness.—"The Gardener." [In France, where this system originated, the usual plan is to cover the glasshouse with straw mats.]

Lilies Seeding.

—I wonder if any reader of THE GARDEN has ever succeeded in obtaining a ripe pod of seed from *Lilium caudatum*, the old white garden Lily. I have done so this year, and have also got a fine pod of *Lilium excelsum*; I hope, therefore, to be able to raise hybrids from these Lilies. Seed of *L. auratum* and *giganteum* is exceedingly thin, so thin that I could not believe it was perfectly formed. However, I see to-day that my *L. auratum* seed crossed with the Giant Tiger Lily is coming up freely; it was sown exactly a year ago, and some *L. auratum* seed from Mr. McIntosh's garden at Weybridge is also coming up well. Dr. Moore tells me that the long-tubed Lily which he showed me at Glasnevin, which was sup-

9. *L. speciosum* (Japan); natural size; imported flowering bulb, with a reduced figure of freshly-dug specimen; colour, white-yellow, orange-brown, or reddish-purple. [See p. 135.]

14. *L. bulbiferum* (Europe and N. Asia)—*L. Thunbergianum*—well-grown flowering bulbs; colour, yellowish white, suffused purple or brown. [See p. 136.]

to be able to raise hybrids from these Lilies. Seed of *L. auratum* and *giganteum* is exceedingly thin, so thin that I could not believe it was perfectly formed. However, I see to-day that my *L. auratum* seed crossed with the Giant Tiger Lily is coming up freely; it was sown exactly a year ago, and some *L. auratum* seed from Mr. McIntosh's garden at Weybridge is also coming up well. Dr. Moore tells me that the long-tubed Lily which he showed me at Glasnevin, which was sup-

posed to be the true *L. eximium*, was sent to him by a missionary in China. I suppose my getting a pod of seed from *L. excelsum* does not disprove the theory of its being a cross between *L. chalcedonicum* and *L. candidum*. Mr. Thompson, of Ipswich, informs me that it was first noticed in a bed of Lilies at Erfart in Prussia about the year 1816.—FRANK MILES, *Bingham*.

WEST'S PATENT ADJUSTABLE TRELLIS.

THIS new trellis, of which the annexed woodcuts are representations, is the invention of Mr. J. F. West, of Lynnmouth Lodge, Reigate. It is a contrivance which will doubtless be useful, inasmuch as it does away with the often inconvenient use of ladders and steps in the operations connected with Vine culture, whether they consist of tying-in or adjusting the shoots, or the more tedious work of thinning the berries. Instead of having to mount to the roof to perform these operations, those who have this trellis fixed can have the Vines brought down to any convenient height, so that in fact they can

West's Adjustable Trellis as Lowered.

be carried out while the operator is standing on the floor. It will be equally available in the case of roof creepers in conservatories, so that if not too costly, it may be regarded as a boon to cultivators. A great advantage belonging to this arrangement of trellis is, that it can be moved gently by gradation to any suitable position, in order to subject any portion of the Vines readily to the sun's influence. The lowering of the trellis cannot in any way injure the stem of the Vine, if trained as

West's Adjustable Trellis.

in the annexed illustration, the deflection being very slight. The trellis may be constructed of either iron or wood; when made of the former, which is preferable in many respects, it combines lightness of appearance with strength and durability; it can, moreover, be fitted to any shaped house. Vines covering a lineal space of 60 or more ft. may be lowered singly or together by turning one handle. In the illustration AA shows the trellis in position and lowered; BB, the chains for lowering and raising; and CC, the drums and pulleys round which the chains work. DD, in the second illustration, shows the form and construction of the trellis.

Christmas Roses from Seed.—Miss Hope doubts seeds being raised from the common Christmas Rose. I had a plant in a pot in the greenhouse, and it seeded so that I can quite believe it would seed more freely in a warmer climate than England. *Helleborus giganteus* (syn. *maximus*) has never seeded with me under the same circumstances—the seed-vessels seem to swell, but there is nothing inside them. What a grand plant this is! I had a bloom more than 4 in. across and a leaf nearly 18 in. wide. There is an immense plant of it in the garden at Monks Park, near Corsham, Wilts, which has evidently been there for many years. The proper time for blooming is from October till January, but old plants of it will continue to throw up flowers till late in February. I expect it would seed readily if crossed with other *Hellebores*: I have no others with

which to experiment, but I expect the famous seedlings raised in the Botanic gardens at Berlin have something to do with it.—FRANK MILES, *Bingham*.

— Last May I gathered from our Christmas Roses several seed-pods just as they were bursting, and sowed the seeds in pans which were placed in a cold frame; as they showed no signs of germinating they were removed in the autumn to a cold house, and about Christmas the young plants began to appear, and now they are sturdy and otherwise in excellent condition. Although Christmas Roses are hardly enough, it is best to sow their seeds in pans or boxes, as under such circumstances they can be placed under shelter during severe frost, which often displaces and kills the young seedlings when just commencing to root.—J. GROOM.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

FEB. 14.

THIS meeting being held in the large conservatory, the choice collections of plants sent by Messrs. Veitch, Mr. Bull, Mr. B. S. Williams, and others, were seen to better advantage than in the Council room, where they have hitherto taken place. The collection of Apples sent by Mr. W. E. Hubbard from his gardens at Leonardslee, near Horsham, was a very interesting one, nearly all the varieties being as fresh and plump as if just gathered, and the whole remarkably well coloured, and well deserved the recommendation of a medal, which was unanimously made by the Fruit Committee. Cyclamens were well represented from several growers, those sent by Mr. James, of Isleworth, being especially noticeable for their vivid colours and compact, floriferous habit. Messrs. Veitch & Sons sent a select group of hardy flowering shrubs, the most remarkable among them being a variety of *Cydonia japonica*, of elegant habit, bearing white flowers and pearly buds. This will be a useful addition to choice, early-blooming shrubs. Orchids were well represented by collections from Messrs. Veitch, Williams, and Bull among trade growers; and Sir Trevor Lawrence, Mr. Michaels, Mr. Terry, Lord Lonsborough, and others, also contributed some fully-grown plants. Special prizes were offered by Messrs. Veitch for their new double *Poinsettia*, and three growers competed, Mr. Ollerhead carrying off the premier award with a well-coloured example, in which the central branchlets were well developed. There can be no doubt as to this being a really first-rate plant, although it has been somewhat injured by over propagation. Mr. Stevens, of Trentham, furnished a bush tree of the *Calville Blanc Apple*, bearing about a dozen large and well-coloured fruits. The following new and rare Orchids and other plants received certificates:—

***Cycas media latissima* (Bull).**—A stately variety of *C. media*, having feathery foliage produced from a stout stem 4 ft. in height. It promises to be a useful conservatory plant, being more graceful than its allies, *C. circinalis* and *C. revoluta*.

***Croton Mortei* (Bull).**—A distinct form, having broadly-ovate, lanceolate foliage, of a dense green colour, veined and blotched with golden yellow. Having evidently a robust habit of growth, and being distinct in its markings, this plant will doubtless prove useful for decorative purposes and for exhibitions.

***Spathoglottis Lobbi* (Sir T. Lawrence).**—A pretty deciduous Orchid of *Bletia*-like aspect, bearing graceful spikes of golden yellow flowers. It is not showy, but well deserves a place in collections.

***Calanthe vestita rubro-oculata gigantea* (Sir T. Lawrence).**—The most stately and desirable of all the *Calanthes*, with the exception of *C. Veitchi*. It is robust in growth, and produces stout, arching spikes from 3 ft. to 4 ft. in length. The individual flowers are larger than those of any other *Calanthe*, and are of a soft creamy-white colour with a deep Roman-red blotch in the callosity between the column and base of the lip. Undoubtedly in every way a first-class plant.

***Odontoglossum Cervantessi decorum* (Sir T. Lawrence).**—This is a great improvement on the old *O. Cervantessi* or *O. membranaceum roseum*, which it resembles in colour and in the concentric bars on the sepals and petals, but the flowers are at least twice the size of those of the type, and the markings on the broad, crisped petals and heart-shaped lip are much richer.

***Cyclamen persicum compactum magnificentum* (C. Edmonds).**—A compact-habited form of the well-known Persian Cyclamen, having very large and well-formed flowers. It will be valuable for breeding purposes, although in its present state it does not appear to be superior to the large-flowered strains advertised by Mr. Williams and other Cyclamen growers.

***Masdevallia chimæra* var. *Wallisi* (Veitch).**—A form of the weird-looking, spectral *Masdevallia*, from which it differs in having darker markings on the flower. It is a free-grower, and, like some of its congeners it, after the manner of *Stanhopea*, pushes its flowers through the compost of the basket in which it should be grown.

***Amaryllis Princess of Teck* (Veitch).**—A shapely variety of a vivid Roman-red colour, and one of the best of a beautiful group of hybrids, which show great variety in their local colour and markings.

Belonging, as it does, to an easily cultivated class of bulbs, this plant will be welcome for decorative purposes.

Cydonia japonica albiflora (Veitch).—A slender-habited variety of a well-known winter and spring-flowering plant, bearing pure white flowers and buds on leafless branches. It is so distinct from the better known crimson-red and blush forms, and it will doubtless prove an acquisition.

Miscellaneous Plants.—Extensive and select groups of Amaryllids, Cyclamens, Orchids, and other plants, came from Messrs. Veitch & Sons, of Chelsea. Among the Orchids we noticed a dozen varieties of *Lycaste Skinneri*, varying in colour from pure white to the darkest rose, with crimson-blotched lips. The flame-coloured *Laelia harpophylla* bore two spikes, and a fresh and vigorous plant of the *Masdevallia polysticta* bore from fourteen to sixteen spikes of white, rosy-dotted flowers; *Masdevallia chimera* var. *Wallisi* bore several of its ferocious, hispid-looking flowers. Perhaps the most interesting, although not the most showy, Orchid in this group was *Dendrobium glumaceum*, bearing fifty or sixty Grass-like spikes of white fragrant flowers among the green foliage, and with this were associated *Odontoglossum Alexandrae*, a good variety, bearing a thirteen-flowered spike; *Cattleya Trianae* in several varieties; a large specimen of the glossy-flowered *Cypripedium villosum*; and a strong plant of the new hybrid *Chysis Chelsii*, bearing a stout five-flowered spike of rich orange flowers. *Anacardium sesquipetale* bore five very good flowers, and the pure white *Odontoglossum Roezli*, contrasted with the rich purple *Dendrobium luteolum*, was much admired. A strong plant of *Dendrobium Wardianum* bore sixteen or eighteen large, wax-like, purple-tipped flowers on two bulbs nearly 4 ft. in length. *Dendrobium endularis*, a new hybrid raised by Mr. Selen between *D. heterocarpum* and *D. japonicum*, with soft, white, star-like flowers, each being relieved by a brown spot in the centre of the lip. *Cypripedium Hayaldianum* is a strong-growing plant, much in the way of *C. Lowii*, and with it was associated *Odontoglossum Caradinei*, a soft, yellow-flowered plant of great interest, being seemingly intermediate between *O. Lindleyanum* and *O. Hallii*. The crimson-purple and white-flowered *Cyclamens*, staged in Messrs. Veitch's collection, were very effective and excellent examples of good culture. A choice group of new and rare fine-foliaged and flowering plants came from Mr. W. Bull, consisting of Orchids and Cyclamens, backed by Palms, Cycads, and tall *Dracaenas* of various kinds. Among these we noted plants of *Uropeidium Lindleyi*, a crimson-petalled form of *Lycaste Skinneri* named *rubella*, *Odontoglossum cirrhosum* with white and yellow brown spotted flowers, and a fine variety of *Cypripedium pubescens*. One of the most effective *Crotons* in the group was the crimson, brown, and yellow-foliated *C. majesticum*, with leaves nearly 2 ft. in length. Mr. B. S. Williams also contributed a group of Orchids, Palms, Cyclamens, Primroses, and Ferns. A plant of *Cypripedium Dayanum* bore a solitary flower, and one of *Lycaste Skinneri* fourteen flowers; with these were associated flowering plants of *Odontoglossum cariniferum*, *O. cordatum* bearing two spikes of rich brown and white flowers; *Goodyera discolor*, remarkably well-flowered; and a group of large-flowered white-fringed Primroses. Mr. Michaels, of Cholmeley Park, Highgate, N., sent a rich collection of flowering Orchids, including about a dozen plants of *Phalenopsis Schilleriana*, *P. grandiflora*, and *P. amabilis*; also a small plant of the chaste, white, purple-barred *Colax jugosus*. Two small-flowering plants of the rare *Vanda Cathcarti* were also noticeable in this group. Among *Odontoglossums* we noted good varieties of *O. Pescatorei*, *O. gloriosum*, and a splendid form of *O. triumphans*. A plant of the thick-bulbed *Dendrobium Wardianum* Lowi bore about twenty-four large, waxy, bright-tinted flowers; *Oncidium fuscatum*, very nicely coloured, and having the varnished disc of the lip larger than usual, was shown in this collection. A similar, but larger-flowered, paler-coloured form, was sent from Sir Trevor Lawrence's collection. Mr. Michaels had a good variety of *Dendrobium luteolum*. Sir Trevor Lawrence also sent a small but choice and highly-interesting group of Orchids, among which we noted *Oncidium fuscatum* var. *pallidum*, and a curious creamy-white-flowered *Catasetum* named *C. Senra*, to which a botanical commendation was awarded. A plant of the new *Masdevallia macrura* bore a solitary, brown, long-tailed flower; also a good variety of *Odontoglossum maculatum* named *superbum*, and a splendid variety of *O. Cervantesi*, which obtained a first-class certificate under the name of *O. Cervantesi decorum*, the individual, soft rosy-brown-barred flowers being fully twice the size of those of *O. Cervantesi* proper. Mr. Dennis sent a profusely-flowered plant of *Dendrobium teretifolium*, having thong-like leaves 1 ft. long and slender-petalled, white flowers, the lip being curled involutely with fringed margins. Messrs. Osborn & Son contributed a well-grown group of Palms and *Aralias* suitable for dimple-table decoration; among them we noted *Aralia leptophylla*, *A. elegantissima*, *A. Veitchii*, *A. reticulata*, and others. The Palms consisted of *Thrinax elegans*, *Geonoma gracilis*, *Calamus leptospadix*, *Areca Verschoffii*, *Dæmonorops fissus*, *Euterpe edulis*, *Cocos Weddelliana*, &c. Mr. Terry, of Peterborough House, Fulham, showed a group of Orchids, among which were *Phalenopsis Schilleriana*, a remarkably small-flowered form of *Dendrobium nobile*, a well-flowered *Goodyera discolor*, *Oncidium serratum*, and *Coleogyne cristata*, all well bloomed. A collection of cut *Camellia* flowers came from Messrs. Veitch & Sons, who also exhibited a choice group of early-flowering and evergreen shrubs, among which we noted the yell-whish-green-flowered *Cornus Mas*; *Azara microphylla*, with glossy leaves and yellow buds; the white-flowered *Cerasus serrulata*; and the unrivalled *Grevillea rosmarinifolia*, one of the most distinct and effective of all early-flowering, hardy shrubs. Mr. C. Edwards, Hayes, Middlesex, exhibited a large-flowered variety of *Cyclamen persicum* named *compactum magnificum*, to which a first-class certificate was awarded.

Mr. Ollerhead, gardener to Sir H. Peck, Wimbledon House, Wimbledon, furnished four well-flowered plants of *Phalenopsis Schilleriana* and several *Dendrobiums* and *Vandas*. A splendid group of *Cyclamen persicum* came from Mr. James, of Isleworth, whose plants were alike remarkable for brilliancy of colour and excellent culture. With these came a dozen plants of *Cinerarias*, the flowers of which were large and shapely, and the habit excellent. Among them we noted crimson, blue, rose and white, maroon-purple, crimson and white, and violet varieties of great merit. Mr. John Willis contributed a large and well-arranged group of fine-foliaged and flowering plants, consisting of Palms, Ferns, Azaleas, Ericas, and Orchids of various kinds. Half-a-dozen large baskets of *Cyclamens* came from Mr. R. Clarke, of Twickenham, among which we noted crimson, pure white, and white and lilac varieties, all excellent for decorative purposes. Mr. Charles Noble, of Bagshot, sent specimens of the golden variegated *Thujopsis borealis* in excellent condition; and a large group of miscellaneous decorative plants was contributed by Mr. Charles Turner, of Slough. Mr. Lee, of Clevedon, sent cut specimens of his new Violet Prince Consort, which bears very large, deep, violet-blue flowers on long stout stalks, which render them valuable in a cut state. This variety may be described as being a slight improvement on Violet Victoria Regina sent out some years ago by the same raiser. Mr. R. Dean showed a charming group of early flowering seedling Primroses, all in good condition, considering the earliness of the season; among them we noted *Rosy Morn*, having bold, crimson-purple, yellow-eyed flowers of good form and substance; *Fairy Queen*, white; *Sulphurata*, soft yellow; *Brilliant*, crimson velvet; *Altaica*, soft lilac, large flower; *Virginia*, white; *Sunrise*, bright crimson; and others. With these came well-flowered pot plants of Violet Victoria Regina, the large, richly-coloured flowers of which are borne on long, stout stalks, and on that account admirably adapted for cutting and for bouquets. From Mr. Aldous, florist, of Gloucester Road, South Kensington, came a miscellaneous collection of *Cyclamens*, *Cinerarias*, Ferns, Palms, and other decorative plants.

Fruit.—Mr. J. Forl, gardener to Mr. W. E. Hubbard, Leonardslee, Hørsham, sent a remarkable collection of fruit, consisting of thirty-three dishes of Apples and six dishes of Pears. Among the Apples we noted *Royal Russet*, Wellington, also the same variety from sandy soil over sandstone rock, much more highly coloured but smaller, *Adams Pearmain*, *Scarlet Pearmain*, *Court Pendu Plat* (very highly coloured), *Alfriston* (very large specimens), *Minchall Crab* (well known as one of the latest of all Apples), *Cockle Pippin* (very good), *Cider House* (a handsome, rosy fruit), *French Crab*, London or *Five-crowned Pippin*, *Winter Nonesuch*, *Cornish Gilliflower* (rather small but of high colour), *Blenheim Orange*, *Hony Morning* (highly coloured), *Red Streak*, *Winter Pearmain*, and others. The Pears consisted of *Beurré Rance*, *Beurré Berkans*, *Josephine de Malines*, *Uvedale's St. Germain*, and *Easter Beurré*. Mr. Joshua Atkins, Lockinge Gardens, Wantage, sent two excellent clusters of *Black Alicante Grapes*; and specimens of *Ord's Apple* came from the Society's gardens at Chiswick. Mr. Harrison Weir sent a cluster of *Mrs. Pince's Black Muscat Grape*, well coloured; Mr. James Batters, of Chilworth Manor Gardens, sent a basket of Mushrooms and a well-grown dish of *Snowflake Potatoes*; white and purple-topped varieties of *Seakale* came from Messrs. Stuart & Mein, Kelso.

NOTES AND QUESTIONS—VARIOUS.

Iris.—I have not yet bloomed the varieties of *Iris Kempferi*, but a plan of the normal variety at Kew last June was one of the most gorgeous hardy flowers which I ever saw—it was labelled *Iris longicata*; but unfortunately that is not an infallible reference. I have not yet bloomed *Iris stylosa*, but a large plant of it in full flower at Ware's seemed to me as delicate as a *Cattleya*. Plant this *Iris* among *Helleborus giganteus* in a quarter protected from the winds of March and April, and you will be well rewarded.—FRANK MILLS, *Bingham*.

Clematis indivisa lobata.—This is an excellent climber for a greenhouse, especially just now, when it is covered with flowers, which will also be found very useful for cutting. It grows freely, blooms profusely, and lasts a considerable time in perfection. Soil that would suit *Camellias* will also do for this *Clematis*; it should be supplied with liquid manure during the growing season.—A. H., *Thorpe-by*.

Salvia splendens miniata.—This is the best of all the varieties of *S. splendens*. Its habit of growth is compact and short-jointed; its leaves are smaller and darker green than those of the type, and they are more heart-shaped. It is a very free-flowering plant, and one which throws out a number of spikes at one time of the brightest scarlet; even in the case of small plants it flowers very freely.—R. H. B.

Echeveria secunda glauca Injured by Damp.—This is much more liable to injury from excess of moisture during winter than from frost. With us it stands the sharpest frost we get if on a dry elevated mound or bank, but on level beds it rots away during such a winter as the present, when rain is the rule and frost the exception.—J. GROOM, *Henham*.

Arbutus magnifica.—We have here several varieties of the *Arbutus*; but amongst them the most ornamental is one called *A. magnifica*, a truly handsome fruit-bearing shrub, but one which I cannot remember having seen anywhere else. It grows from 20 ft. to 30 ft. in height, its leaves are shining green, the flowers white, drooping, and bell-shaped, and the fruit, when fully matured, the very counterpart of an ordinary-sized highly coloured, ripe Strawberry. Trees of the size just named covered with drooping fruit similar to that described have an attractive appearance on a December day; while for Christmas-tide decorations no other berried tree or plant of any description can be so all compared with them.—A. B. YORGE.

[Vol. XI.]

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

WILD FLOWERS ABOUT ROME.

ROME just comes within the zone of perpetual vegetation; Florence, scarcely 200 miles to the north, though with its Aconites, Anemones, and Tulips, may perhaps have a more brilliant early spring, yet it has also six weeks or two months of midwinter, during which there are no wild flowers at all; whereas at Rome, from January 1 to December 31, go out when you will, you will be sure of finding more than one plant in actual bloom. Many of our New Year's flowers are those common to the English spring, several small kinds of Veronica, a few Dead Nettles, Celandine, Fumitory, Ajuga, &c. I need not remind any visitor to Rome of the Violets, which all through the winter are to be found in such abundance in the Villa Pamphili Doria, nor of the Anemones, both the garden *A. coronaria* and the purple *stellata*, which carpet the meadow in front of the Casino. But there are other flowers unknown in England which, taken as a group, are, I believe, enough to distinguish the flora of Rome from that of every other place in the world. Our commonest flower, though marked in the books as found all through the Mediterranean region, grows neither at Florence nor Naples, while within a narrow circle round Rome it is universal: this is *Diplotaxis erucoides*, a Crucifer allied to the English cornfield Charlock, but with a white flower more or less tinged with purple. All through the winter the Vineyards are white with it, and though cartloads of the plant are brought into the city daily as fodder for cattle, there is always a sufficient quantity left to supply any number of cheap bouquets to throw about in Carnival time. Along with it blooms the Marigold (*Calendula officinalis*), a plant which, wherever the traveller from the north finds it, assures him that he has left the region of bitter cold for one in which the sun never loses its power. Another plant (which, though found elsewhere, as in the warm south-east corner of France, is nowhere so abundant as it is here), is *Erodium romanum*, a species closely allied to the common Crane's-bill, but distinguished from it not only by the time of flowering, but also by being stemless, and sending forth its flower-stalks immediately from the root. Its clear, pale pink flowers of considerable size, together with its winter blooming, would almost recommend it for cultivation, but for certain faults of habit; the flowers open separately, or never more than two at a time, and the petals are so easily shaken off that it is almost impossible to gather the flower. In the herbarium the petals almost always detach themselves from the stalk while the plant is being dried.

A starveling Daisy sometimes ventures to push up its head in a mild December in England, but here Daisies are really what Shelley describes them to be—

Pearled Arcturi of the earth,
The constellated flowers that never set.

And we have two others along with the common kind—*Bellis sylvestris*, with a tall stalk sometimes quite 1 ft. high, which, in spite of its specific name, studs the most open and barren parts of the Campagna from autumn to spring with its pink and white blossoms; and *Bellis annua*, which, in the first days of January, spreads a sheet of starchy little flowers over the damp, sandy spots which occur but too often in the neighbourhood of Rome. With it, or in the low fallows, is found *Anthemis fuscata*, a near relation of the common Chamomile, and, like it, with strongly aromatic flowers. This plant also is characteristic of the Roman flora, as its northern limit seems to be Orbetello, in the extreme south of Tuscany. Another plant which is now in bloom should be mentioned, because it is in itself extremely graceful, and is at the same time a distinctive feature in the flora of South Italy: this is *Sonchus tenerrimus*, one of the despised family of Sow-thistles, but as different from the clumsy weeds we know in England as the sun of Italy

is from that of the north. It has an abundance of slightly glaucous, slender-winged leaves, with yellow flowers in which there is nothing remarkable, but its elegant mode of growth, and the posts of vantage which it takes up, render it specially noticeable. It leans out from a niche in an old wall as if to contrast its luxuriance of growth and intricacy of outline with the crumbling and degraded ruin from which it hangs; or it springs in full vigour of life from some little crevice where there seems scarcely a root-hold, to prove the power of southern light and air which, almost alone and without help from the earth, call forth such intense and overflowing vitality. Here in Rome, indeed, it cannot be said to display its full character—there is still something of a chill in the air which depresses its energy of life; but at Messina or Palermo you see it bursting from every nook and cranny, and adjusting itself to every strange position into which the wind has carried its seed, with unflinching grace and effect.

I will mention one more curious plant, which is found in the yellow sands which cap the low Miocene hills on the right bank of the Tiber: this is *Allium Chamæmoly*, quite unlike all other Garlicks in its outward appearance, but recognizable at once by the peculiar strong odour which marks all the genus. It pushes up three narrow, lanceolate leaves which lie flat upon the ground, and between them, just peeping above the surface, is the umbel of little white flowers, what stalk it has being quite subterraneous and never rising higher than at first. This is a way of growth which is not uncommon among Cape bulbs, but I do not know that there is another example of it in Europe. At the Cape of Good Hope the plants seem to try to hide themselves as far as they can to escape the heat and drought; this little winter plant perhaps tries by the same device to shelter itself from the cold. However this may be, *Allium Chamæmoly* is an illustration of Darwin's dictum that Nature is always working towards extremes.

EDWARD ARMITAGE.

GROWING RARE HARDY PLANTS.

I AM glad to see Mr. Miles coming prominently forward as an enthusiastic cultivator of plants. Nevertheless, will he permit me to offer a few remarks upon his article (see p. 121) about growing rare hardy plants? Though his plants seem to be at their best, yet I think it might be just as good or even better to plant the bulbs of *Calochorti* and others right in the soil, and to put the sand and cinders beneath the vegetable soil rather than above it; it is a principle generally adopted to imitate natural conditions as nearly as possible, in order to bring plants to perfection in our sometimes very adverse climate. As far as I know, *Calochorti* grow in their native places in strong, loamy soil, lie dormant during the dry season (that is, from July to October), grow underground from October to March, and then rapidly appear among floods from melting snow and rain, and complete their growth amid spring weather, dying down under the hot sun of the far West. Of course, in our changeable climate we may adopt different means to grow and preserve them. I have grown these plants for many years, and I am convinced that in order to have good blooming bulbs, they must be constantly renewed from seed. If once allowed to ripen seed, they die away, either in the same or following year. They may be induced to last longer if the seed-pods be picked off immediately after flowering, but I have found that the same bulb will never be as good as it was before it bloomed. I grow them in pits, well drained with some 4 in. or 5 in. of broken bricks, and on these a layer of sand. In winter they are protected from frost by a frame and coverings, and in autumn they are kept dry by the same means; while from April to July they are exposed to all weathers. The seed should be sown as soon as it is ripe; it germinates in the following spring, and the small bulblets are planted in October in beds or pits as above described. There they ought to remain undisturbed till they flower, which they will do in the third year. Even in the climate of England, which is far more suitable for the growth of half-hardy plants than ours, such pits would be found to be useful for amateurs, inasmuch as by means of them we are at once enabled to keep our pots from frost or rain just as may be required. Every year I add some decomposed manure and a little old mortar rubbish to the soil, and use the same beds for many years. Even *Bletia hyacinthina* I grow in such beds, and it flowers with me every year. The soil used is one-third common garden-soil, one-third leaf-mould and peat, one-third decomposed cow-manure, loam, and sand, to which is added a little old mortar, as many bulbs are fond of chalky matter.

Baden Baden.

MAX LEICHLIN.

CHRYSANTHEMUM CUTTINGS.

I WANTED a stock of Chrysanthemums, and not having any of my own I naturally looked about to ascertain how I could get them at the least cost. In last week's number of THE GARDEN (see p. 123) I noticed some useful remarks on the subject by Mr. Margetts, of Lyddington, in this county, but I take exception to his preference for purchasing plants in April to getting cuttings from the nurseries in winter. The former may occasion the least trouble; but is anything gained by it on the score of economy? I think not. Early in January I received from a friend residing a long way off, and by a two days' post, a small packet of cuttings, three-fifths of which are now doing well. Two of the sorts I found this morning (Feb. 19) required re-potting, and I had the curiosity to measure the length of the longest root, and found that when shaken out it measured exactly 10 in. from the heel of the cutting to the extremity. I also obtained about the same time a dozen cuttings from Mrs. Dixon, of 34, Moorgate-street. Some of them were very small, and to my inexperienced eye looked most unpromising, but I planted the lot with great care, and now more than half will certainly make good plants. In the treatment of these cuttings I was guided by the directions given in a December number of THE GARDEN; they are placed under bell-glasses, the pots standing on slates, with a layer of Cocoa-nut fibre and silver sand, kept moist between the slates and the bottom of the pots. The glasses, each of which covers three pots, were removed daily at first for about an hour, but now those that have not yet been re-potted and removed remain uncovered the whole of the day. They stand in a warmed but thoroughly ventilated greenhouse, the back shutters of which are left open even at night when frost is not apprehended. Of the variety named Mrs. Dixon, stated to be "the finest yellow in cultivation," the three sent are in full vigour. Had they been plants when I received them instead of cuttings, they would certainly have been charged double the price, and I doubt if the risk of transit after the cuttings have been rooted exceeds very much that of those sent out at an earlier period in an unrooted state. If the nurserymen, when sending them out, would always make a point of withholding any cuttings that are not likely to strike, I believe there would be very few failures among them when properly treated by the purchaser, and there is always some satisfaction afforded to the amateur in raising his own plants. I found the moistened mixture of sand and Cocoa-nut fibre very useful between the bottoms of the pots and the slates on which they rested. Under one of the pots 4 in. of root protruding from the hole had worked into this medium, and not a fibre was lost in re-potting the plant. The tendency to emit roots is so strong in the stalk of the Chrysanthemum that any one who does not mind the trouble of raising it from cuttings will find it worth his while, when in want of new varieties, to get them in that form in winter rather than wait till April for rooted plants. Nevertheless, Mr. Margetts deserves our thanks for giving us his experience in growing the Chrysanthemum, in which he appears to have met with great success.

Rutland.

B. S.

CRINUM AMABILE IN THE SUB-TROPICAL GARDEN.

Now that sub-tropical gardening has become so fashionable, and plants of noble aspect are in request to carry out a form of embellishment so justly admired, the *Crinum amabile* should not be lost sight of, for not only is it most valuable for outdoor decoration during the summer to place in the centres of beds, or for plunging in certain positions to stand out in bold relief as single specimens, or in grouping among others of similar character, but when seen in the stove with its huge heads of Lily-like flowers, it is, indeed, a grand object, and one which produces a striking effect. To those unacquainted with this noble plant, some idea may be formed of its size and appearance when it is stated that an ordinary-sized bulb measures over 2 ft. in circumference, and has a thick, fleshy stem gradually tapering up from 12 in. to 18 in. high, with thick, broad leaves at least 3 ft. long, that spread out elegantly in every direction and droop in a very graceful manner. The flower-stem starts out from the upper part of the neck of the

bulb just below the leaves, and is generally about 3 ft. long and large in proportion, bearing from twenty to thirty blooms of a rosy-purple colour, and in form much like the well-known Jacobean Lily. Although not very lasting, they open a few at a time, and are most useful for cutting singly to associate with others, with a few sprays of Fern arranged on bright green Moss in low dishes in the same way that Orchids, single blooms of Eucharis, and other choice subjects of that description are generally shown. To grow the *Crinum amabile* well, it must have plenty of pot-room and good, rich soil, such as a strong fibry loam chopped up and used in a moderately rough state, about one-eighth of its bulk of well-rotted manure, and just sufficient sharp sand to keep the whole open and porous. Owing to the great quantity of water required when the plant is making rapid growth or is sending up flowers, it is very important that the drainage should be efficient, otherwise the ball will become sodden and sour, and, instead of healthy roots, they will rot away. As a rule, all plants that have such large, fleshy feeders, besides being exceedingly fond of plenty of water at certain seasons, require the soil to be loose that they may ramify freely in it, and the *Crinum* is no exception to this. In potting, the turfy loam should therefore be placed somewhat lightly around the ball and not be pressed firmly together, as is usual in the treatment of most other plants. The rapid rate of growth of this and the number of large fleshy roots it forms render it necessary to employ rather a large-sized pot, especially if the object be to get fine leaves as well as flowers, in which case a smaller size than 18 in. ought not to be used, and even then it should be freely assisted with plenty of clear liquid manure as soon as it gets at all pot-bound.

Although a native of the East Indies, the *Crinum amabile* does not require strong heat, as it will succeed well in an ordinary stove, and may be wintered in a temperature as low as from 50° to 55°, if kept tolerably dry at the roots. One great advantage in growing plants of this description is, that they are serviceable at all times, either when in or out of bloom, and the exposure they get, when doing duty in the flower garden or other position in the open air, is just the treatment many of them require in order to get them thoroughly ripened and in a fit condition to produce their flowers in a free manner when housed. Whether used for outdoor work or not, full exposure to the sun is one of the first requisites if a free-blooming habit be desired, and to aid in this, water should be given less frequently after the plant has completed its growth. The slow rate of increase of *Crinum amabile* makes it somewhat dear to purchase, as it can only be propagated by the offsets it sends up so sparingly at the base of the bulb. These should be allowed to remain till they have emitted a few roots, when they may be removed with safety if the operation be conducted in a careful manner so as not to bruise or injure the base of the thick, fleshy stem. When severed from the old plant, it is best to allow this part to get a little dry and healed before potting, by letting it lie exposed in the stove for a few hours, as there is more danger of losing them from decay than in any other way. The large, sappy stem will contain sufficient moisture to sustain it till it gets fairly hold of the soil, or till such time as the bare part at the base has healed over, when by giving a little water it will soon start into growth. The proper time to remove these offsets is early in spring just as the plant is forming fresh leaves, when they are sure to succeed if potted in very small, well-drained pots in sharp, sandy soil, and afterwards plunged in a brisk bottom-heat where they can be kept well up to the light, which is essential for their well-being at all seasons.

S. J.

Culture of *Sparaxis pulcherrima*.—I have not yet grown this grand plant well. We are all fond of talking of our successes, but I should never cease talking if I once began on my failures. At Messrs. Backhouse's nursery at York, this plant and its deep maroon variety (*S. p. atropurpurea*) grow fully 4 ft. high, and flower in profusion on a rather sandy, warm soil. It is easily raised from seed, and I have seedlings only two years old which will probably bloom during the summer. Messrs. Barr and Sugden tried the experiment of leaving *Ixia*s out on raised beds without protection in winter. I wish they would let us know the result. I have a raised bed in the open ground

of *Ixia* and *Sparaxis*, and they are growing well, but this winter is a very exceptional one. At Mr. Ware's I saw a bed of the *Ixia* called Wonder in full flower, but the frost seemed to have severely damaged the leaves.—FRANK MILES, *Bingham*.

GOLD-LACED POLYANTHUSES.

INQUIRIES are constantly being made as to the sources whence some of the fine old-named Gold-laced Polyanthuses can be obtained. The fact is, it is very difficult indeed to obtain them, and so scarce have they become, that on the occasion of the annual exhibition of the National Auricula Society, in no class was more than a couple of plants required. A pair of dissimilar varieties brings but a small competition, and the leading flowers are Cheshire Favourite (Sanders), Earl of Lincoln (Hulton), Exile (Coishaw), Lancer, and Kingfisher (Addis), and George the Fourth (Buck). I have made many attempts to gather together a collection of these Polyanthuses, and I have Lancer, dark; Cheshire Favourite, red; and Hilton's President, dark red; but beyond these I cannot as yet proceed. I am particularly desirous of obtaining Exile, Earl of Lincoln, and George the Fourth. As some may be disposed to ask why these varieties are not more plentiful, my reply is, that they have been subjected to such a sweating system of culture, and divided so remorsefully, in order to obtain fresh plants, that their constitution appears to be greatly impaired. If one of them throw an offset, it is applied for on every hand, so many being anxious to obtain it. My plants were very small when I first received them, but now, by means of careful culture, they are gaining strength, and will shortly furnish offsets. Last spring, as soon as the plants had bloomed they were planted out in a cool east border, where they had some shade during hot weather. A good loam bed 12 in. in depth was made up with some decomposed cow manure and leaf-mould mixed with it, and the plants were pressed firmly into the soil after being turned out of the pots with all the soil adhering to them. They were well watered during dry weather, and they made good growth during the summer. At the end of August they were lifted, the soil was taken from their roots, which were examined, and the old part of the tap root cut away to within $\frac{1}{2}$ in. or so of the leaves, leaving, however, a good supply of fibrous roots. They were then re-potted in a good soil made up of loam, leaf-mould, decayed cow manure, and a little gravel sand, and were then placed in an Auricula frame. They have made vigorous growth, and will soon commence to throw up flower-stems; I therefore anticipate some good flowers and useful seeds. My Lancers in particular are looking remarkably well, and are throwing up strong offsets from the roots. If I were growing for exhibition it would be necessary to take these off in order to throw all the strength possible into the parent plant; but as I am not, the offsets will remain till planting-out time, by which time they will have grown into strong plants.

D.

Myosotis dissitiflora and the Rain.—Mr. Fish's experience of the effects of the long-continued rains upon this early Forget-me-Not differs entirely from mine this season, as I never had it in finer or healthier condition. Some years since I found it necessary to differ from Mr. Fish as regards the superiority of seedling plants over those propagated from the old ones, and I still believe that seedling plants are, as a rule, the most trustworthy. Last year, because of the almost entire failure of the seed crop, I had to produce a stock of plants from the old stools, and in September these were lifted, pulled to pieces, and the rooted shoots dibbled out in large beds to the extent of many hundreds. I do not think that 5 per cent. of the whole have died, and in one bed of about 600 plants not one is missing, and just now all are covered with bloom-heads bursting into flower, and ready to lift into 48-sized pots for decorative purposes. This *Myosotis*, in spite of its hardy character, is nevertheless somewhat difficult to cultivate freely in pots. If kept in a dry, warm temperature it is soon smothered with green fly, and if kept in cold frames it is very subject to damp and to rotting in the centre of the plants. Because of these possible evils I do not lift into pots until the bloom-buds are well developed, and this should be done upon a dry day, and water should be given carefully at the side of the plant and not in the centre. Under glass they soon come into flower, and when once fairly in bloom there is no danger to be apprehended from damp. It is still one of the most beautiful and earliest of all hardy bedding plants, and, when grown in masses in contrast to other colours, has no equal.—A. D.

The Edelweiss.—The idea that this plant is difficult to cultivate has probably arisen from its appearance when at rest. In autumn it dies down to a small bud which lies dormant during winter, and in this state it looks as if entirely dead, no trace of life being visible to the inexperienced. The consequence is the plant gets

thrown away or eradicated. If planted in rich soil it does not look so pretty as it otherwise would do, because it grows more vigorously, and the down is washed away by the incessant rains, so much so that by such treatment the production of down on the leaves ceases entirely. In its natural habitat I always found the finest patches at places where they were protected by overhanging rocks, and where they seldom got rain, but were protected by snow in winter, the snow being driven on them by wind. It is moreover a fact that where birds regularly roost, the plants get finer and stronger than elsewhere, and under cultivation I have seen a sprinkling of pigeon's manure induce this plant to produce very large flowers.—MAX LEICHTLIN, *Baden Baden*.

St. Bruno's Lilies.—How few people grow or even know St. Bruno's Lily (*Anthericum Liliastrum*)! It is exactly like the White Lily in miniature, growing late in the spring months $1\frac{1}{2}$ ft. to 2 ft. high, and flowering profusely. A large and fine variety was figured last year in THE GARDEN (see p. 12, Vol. IX.). *Anthericum Liliago* is another lovely plant for the herbaceous border, with star-like flowers on thin, bending stems. The variety sold as *A. Renanii* is much finer in growth and flower, being fully 3 ft. high. *Anthericum ramosum* I am delighted with; it bears pendent stars on small stems, and is tall and tender in form, but quite able to take care of itself in the borders. All do best in turfy loam.—FRANK MILES.

Drying off Bulbous Plants.—I agree with Mr. Groom (see p. 121) that this is a bad practice. Nature and reason alike show it to be wrong, and this more especially in the case of those plants which are natives of temperate and northern climates, and which "rest" during the cold or winter season, a time during which they receive more moisture than when they are making their growth. The truth is that very few bulbs, if we except those in the most arid regions, really do rest after the foliage dies down, but go on rooting and developing buds or offsets ready for next year's growth and bloom. This is especially the case with Lilies, Irises, Crocuses, and many other bulbs which are actually injured by being dried off during the winter, although taking them up carefully and re-planting them in fresh soil may, under certain circumstances, be necessary and even beneficial. Because Hyacinths, Lilies, Tulips, and other bulbs are dried off by Dutch and other bulb-growers for the conveniences of trade, many cultivators have concluded that such treatment is a necessary part of bulb culture; on the contrary, however, it is a most pernicious practice. Lilies especially root freely in all directions, and distend their scales and buds all through the most severe winter weather, if planted in porous, well-drained soils; and to stop this growth paralyses, and in some instances actually kills the bulbs. The best way with hardy bulbs is to plant in rich, well-prepared soils on a well-drained bottom, give abundance of moisture, and never take them up unless it be to re-plant them in better soil immediately. If this practice were followed, we should then have fewer failures in bulb culture than we now have.—B.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Roman Hyacinths.—These planted in open borders fully maintain their early habit of flowering; they are now (Feb. 8) in full bloom. In sheltered positions they will form interesting additions to the spring garden as companions to the several varieties of Crocuses.—J. G.

—Is your correspondent Mr. Danning sure that his Roman Hyacinths really rot when left in the ground? I have now a small patch in bloom which has been dormant for four years. I believe this Hyacinth is a distinct species, and rightly named *Hyacinthus precox*.—H. HARPER CRAWE.

Verbenas treated as Annuals.—From what I read in THE GARDEN in the early part of last year respecting Verbenas treated in this way, I at once sent for seeds which in due time were sown on a well-prepared bed, but not a single plant came up. Had I not sown some of the same seed in pans, I should not doubt have blamed the seed, but I could not do that, inasmuch as nearly all of it sown in that way came up. I had, therefore, plants sufficient for my bed, a circumstance which somewhat mitigated my disappointment.—E. MILLER, *Old Sneyd Park, near Bristol*.

—Like "H. M." (see p. 125) I adopted the suggestion respecting the raising of seedlings, but I sowed the seed in shallow pans, pricked off the seedlings into boxes, and finally put them into beds in May. Under this treatment they proved satisfactory, producing a great variety of colours, and exceptionally strong plants. To sow such small seeds where they are to grow permanently would be anything but a saving of labour, and in the majority of cases would prove a failure.—J. GROOM, *Henham*.

Forming a Rose Garden.—In answer to Mr. Gilbert (see p. 103) allow me to say that I have found that Briers, planted where they are intended to remain and worked afterwards, will last much longer than trees obtained from a nursery, as nurserymen too often plant mere sticks which never make good roots; under such circumstances they yield a few blooms, and the second or third year disappear. From what I have seen in this neighbourhood and elsewhere of seedling Briers, I would strongly recommend them on account of their health and strength. If I had to make a Rosery I should certainly plant it either with seedling Briers to bud, or with trees already budded on that stock.—W. DIVES, *Winton*.

NOTES OF THE WEEK.

A GOOD BEGINNING.—Many of the ugly flower-beds, under the crowded trees by Piccadilly, are now being turfed over. It would be no loss but a great gain to gardening if ten out of every twelve "flower-beds" in the United Kingdom and in Europe were also turfed over.

A LARGE PAMPAS GRASS.—We have received from Mr. J. F. Marsh, of Hardwick House, Chepstow, a photograph representing a very fine specimen of this noble ornamental Grass. It measures 12 ft. in height, and upwards of 14 ft. in diameter, and bears silvery plumes in profusion and of unusually large size.

THE PEARL-BUD SPIREA (Exochorda grandiflora).—The plate in our present number was drawn by Mrs. Duffield from a fine specimen in Mrs. Harrison's garden at Weybridge Heath. This beautiful shrub flourishes freely round London, and deserves a place in every garden.

ONCIDIUM SPLENDIDUM.—Small plants of this new *Oncidium* are now flowering freely in Messrs. Veitch's nursery at Chelsea. Its sepals and petals are beautifully marked, and the lip, which is large and flat, is of a rich clear yellow colour. When more plentiful, this *Oncidium*, the flowers of which are large and showy, will doubtless find a place in every collection.—S.

THE SKUNK CABBAGE (Symplocarpus foetidus).—This curious plant (for specimens of which we are indebted to Mr. Ware, of Tottenham) is now in bloom, and its bronzy-purple cowl, marbled with green, are not without beauty when closely examined. Its leaves, which develop later, are very large. It is worthy of a place in the wild garden, and thrives in moist, deep soil.

THE CITY OF PARIS NURSERY GARDEN.—It having been several times reported that this was removed to the Bois de Boulogne, it may be as well to state that it is in complete working order in its old position—La Mnette, Avenue d'Eylau. It contains a fine collection of plants, and various large houses devoted to popular classes of plants, such as Camellias, Ferns, Palms, &c. A great deal of glass is devoted to the production of plants for the summer decoration of the parks and squares.

EARLY FLOWERS IN BUCKINGHAMSHIRE.—I have had *Crocus Imperati* in flower here since Christmas, and a beautiful bed it makes, the interior of the blossoms being violet-purple of the most lovely description, and the outside fawn striped with purple. The different kinds of *Hellebore* have also done well this season. *Iris reticulata* is likewise in charming condition, and so is *Scilla bifolia*. Altogether this has been a favourable season for early flowering plants.—J.M., *Windsour*.

A CEMETERY CONSERVATORY.—We have received photographs of the interior of the conservatory chapel in Forest Hill Cemetery, Utica, New York. In this cemetery the excellent idea of a conservatory chapel, full of flowers and fine-leaved plants, has been carried out successfully. We should have engraved one of the views were it not that the beams and other supports are as yet too predominant, as compared with the vegetation.

CYPRIPEDIUM ROEZLI.—For continuous blooming few of the *Lady's Slippers* equal this. Large plants of it in Mr. Day's collection at Tottenham have for the last two months been well furnished with strong flower-spikes 3 ft. or 4 ft. in length, and thickly beset with soft, delicately-tinted blossoms; the spikes, which keep on growing, produce blooms at their extremities, and thus last in good condition for a longer period than other varieties. The plants in question are still throwing up new flower-stems, and will be attractive for some time to come.—J.

PELARGONIUM ROSEUM MULTIFLORUM.—This comparatively new *Pelargonium* is doubtless a good step in advance of other early-flowering varieties, inasmuch as the plant assumes a more dwarf and compact habit of growth, and is far more floriferous than the kinds usually employed for forcing. The blooms, too, are large and of good colour.—C.

NEW MODE OF HEATING.—Mr. Cannell, of Swanley, who has recently erected several new houses in his nursery there, has had them heated on quite a new method. Instead of the pipes running along the sides of the houses low down, as is generally the case, they are placed close up to the glass. Small hot-water pipes are also distributed about the roof, a plan of heating which has proved advantageous this wet season, inasmuch as the foliage of the plants has been kept free from damp without an unnecessary amount of heating power being used. Whether, however, this system be right or wrong, the plants subjected to it appear to thrive, the whole of the stock being exceptionally vigorous and healthy.—S.

DOUBLE PRIMULAS AT ST. JOHN'S WOOD.—The *Primula-house* in the Wellington Nursery is now very attractive, containing, as it does, hundreds of stocky plants, loaded with large double and semi-double blossoms of nearly all shades of colours. Some of the white kinds are especially attractive, the blooms being as large and double as those of a *Carnation*. Plants of these should be largely grown for conservatory decoration, especially such kinds as *Princess of Wales* (white), *Emperor* (dark purple), and *Miss Eva Fish*.—S.

CARNATION AND PICOTEE SOCIETY.—We have received a copy of the proposed schedule of the *Carnation and Picotee Show* which is to be held in London in July next. There are ten classes, and the value of the prizes range from 70s. downwards. A list of supporters is appended, showing that upwards of £40 has already been subscribed, but further aid is solicited by the secretary Mr. E. S. Dodwell, 11, Chatham Terrace, Larkhall Rise, Clapham.

ODONTOGLOSSUM ANDERSONI.—A plant of this comparatively rare *Orchid* growing in one of the houses at Gunnersbury is now bearing a strong spike of bloom furnished with fifty-seven large, sweet-scented, and beautifully-marked blossoms. This is decidedly the largest and best flowered spike of this *Odontoglossum* which I have yet seen.—S.

VARIEGATED FIGUS.—Messrs. F. & A. Smith have now growing in their nursery, at Dulwich, a new *Ficus*, which will no doubt prove a good companion to the well-known *India-rubber Plant*. In habit the two are a good deal alike, but the leaves of the new kind are produced more closely together than those of *F. elastica*, and are beautifully blotched with pale yellow. Established plants of it are expected to be even more effective as regards colour than those in a young state.—S.

THE BEST PEARS AND APPLES NOW IN SEASON.—By far the best Pears now purchasable in the London market is the *Easter Beurré*, sent all the way from California, and this year in greater abundance than before. They come without packing material (beyond one thickness of slight brown paper round each fruit), in boxes 20 in. long, 12 in. wide, and 9 in. deep. Curiously enough, they are seldom bruised when thus sent, though parts are often a little flattened. The fruit is much more unequal in quality than that sent during previous years. The differences shown are no doubt traceable to the wide variation of the climate of California. The best Apple and the only one now worth eating as a dessert fruit is the *Newtown Pippin*, which has been in use for the last four months.—P.

CAMELLIAS AT DULWICH.—The *Camellias* in Messrs. F. & A. Smith's nursery here are just now finely in bloom. They consist of many hundreds of bushes of nearly every known variety planted out in beds. Amongst the best may be named *Mathottiana*, a kind with very large scarlet blossoms; *Duchess of Northumberland*, white with carmine stripes; and the beautiful white, fringed *Fimbriata*, a variety in its way as yet unsurpassed. This collection also contains a new seedling as yet unnamed, but which is to all appearance a distinct and valuable sort. Its flowers, which are bright pink edged with white, are so full of petals as to form a perfect cone; the foliage, too, is large and fine, a matter not to be lost sight of when selecting *Camellias* for planting out in conservatories.—J.

HELLEBORUS COLCHICUS.—This variety of *Christmas Rose* is now finely in bloom in Messrs. Henderson's nursery. It is a spring-flowering kind, the blooms of which are of a drooping character, and of a dark purple colour with a cluster of white stamens in the centre. They are produced on long stems, and are therefore very useful for cutting, a condition in which they last for a long time, and are valuable either in vases or bouquets early in the year; they may be gathered from the end of February until the middle of April.—J. T.

SMITH'S CINERARIAS.—The *Cinerarias* in Messrs. Smith's nursery at Dulwich are just now in full bloom and well worth seeing. They are arranged in low span-roofed pits, 100 ft. in length and proportionately wide, and, as they may be counted by hundreds, they are strikingly showy. The flowers, which are large, are of good shape and bright in colour, scarcely two plants being alike. When in full bloom, plants bearing the best-coloured and best-shaped flowers are picked out and put away for another year's stock, the rest being allowed to seed. Any found with inferior blossoms are immediately thrown away to prevent them from fertilizing the others and thereby spoiling the "strain."—S. F.

EUSTON SQUARE.—This square, which has so long been in a disgraceful state, has at last been planted and arranged by Mr. Neal, of Wandsworth Common. Many fine *Weeping Ash* trees have been killed, owing to the quantity of rubbish heaped over their roots.

TREES AND SHRUBS.

A NEW BERRY-BEARING SHRUB.

(HYMENANTHERA CRASSIFOLIA).

THIS is a dwarf evergreen shrub, characterized by a much-branched and somewhat rigid habit, the slender branches being clothed with tufted or alternate leathery leaves, about $\frac{1}{2}$ in. or $\frac{3}{4}$ in. in length. The flowers, which are small and inconspicuous, are succeeded by thickly-set white berries, as shown in the annexed engraving, which represents a mere fragment of a well-grown pot specimen sent to THE GARDEN office by Messrs. Veitch & Sons during the past winter, at which time it was particularly attractive, forming a dense bush, say from 15 in. to 20 in. in height, one mass of leafy twigs, the bases of the branches, and even the thick old stems, being decorated with white berries, their colour being heightened by contrast with the ash-coloured bark, and still further by minute black dots on the fruits themselves. Both as a neat-growing, hardy shrub, and as a pot plant for cool greenhouse or conservatory decoration, this plant well merits extensive cultivation. It is a native of New Zealand, and is interesting as belonging to the Violet family, to which in external appearance it bears not the slightest resemblance. B.

Trees on which Mistletoe is found.—There appears to me to be a great many different opinions about this plant. A writer in "Cassell's Magazine" for December says that "popular opinion imagines the Mistletoe to be chiefly parasitic on Apple or Crab trees, whereas it is really very rare on these. We have collected the names of upwards of thirty trees, native and introduced, on which the Mistletoe has been found growing. Of these the Thorn is perhaps that most affected by it. It was on account of the rarity of the occurrence of the Mistletoe on the Apple tree, that the Druids gathered it from the Oak; and again, in a paper lying before me I find this sentence, "that it (the Mistletoe) will not grow on any other than Apple and Oak trees;" in reference to the first assertion I can say from personal observation that if any one can go into an orchard in any part of Herefordshire and not find Mistletoe growing on the majority of the Apple trees, it will be quite an exception to the general rule in that county, and anyone who makes a tour of the rivers Wye and Lugg will notice great masses of the sacred plant growing profusely on the Aspen Poplar tree. I have only seen it growing on the Apple, Aspen, and Oak trees, that is, in Herefordshire, Gloucestershire, Worcestershire, Monmouthshire, and Radnorshire. I never heard of it growing on the Thorn, but I suppose the writer means between Calais and Paris; and I was under the impression that the Druids venerated the Oak for its Mistletoe. Was the Apple or Crab known in Britain then? Will some of your readers give a list of the localities and names of the trees on which, and where the Mistletoe may be found? How is it there is no Oak or Mistletoe about Stonehenge or Avebury in Wiltshire?—C. E. B.

Evergreen Underwood.—I find most of the varieties of Box to be very serviceable as evergreen underwood, especially under deciduous trees. Some of the drooping variegated varieties are really beautiful in large clumps, and for decorative purposes I usually get our main supply from the woods, so that those in the shrubberies may be left undisturbed.—J. GROOM, *Henham*.

EXHAUSTIVE EFFECTS OF TREE ROOTS.

THE distance to which certain tree roots extend in cultivated grounds is a subject of some importance, as in many instances where they have originally been planted to provide shelter, or as screens to hide unsightly objects, they eventually become a great source of injury and annoyance, on account of the roots penetrating the ground and robbing it of the food intended for the use of culinary or other crops. The amount of injury thus inflicted is especially apparent during seasons of drought, and it is an evil not easily cured, as the removal of the trees would in some cases be considered a greater loss than the injury which they commit, so that half-measures have in most cases to be resorted to, such as cutting back as far as possible; but having once found a rich feeding ground, this only causes them to grow out hydra-headed and increase with tenfold vigour. The distance to which certain tree roots run should be taken into consideration when planting, for while the roots of many evergreens—the most serviceable as shelter trees—do not extend further from the base than

the height of the tree, others, especially those of the Ash and Elm, extend in light soils double the distance of their height: if fruit trees were such rapacious feeders, no profitable cultivation could be carried on in their vicinity. The custom of planting forest trees in hedgerows affords an illustration of the folly of attempting to grow one crop over another, for there cannot possibly be a good hedge in connection with them, as the trees naturally become masters of the situation; and as to timber, whoever saw hedgerow timber a century old worth the injury which it had done to surrounding crops? Indeed, scarcely one per cent. of trees planted in such positions ever attain timber size at all, for hedgerows being as a rule planted on elevated banks, the trees perish before they have a chance of becoming established. A writer in an American paper (see 85), in alluding to pasturing Apple orchards, gives some sound advice on double cropping; he says:—"Try one crop and pay attention to it, and you will have no cause to complain of results;" in like manner, where cultivated lands are undermined with gross-feeding tree roots, the most skilful cultivator will be unable to produce satisfactory crops. J. GROOM.

Henham.

Golden Ivies.—Can any of your readers inform me if there is a Golden Ivy in cultivation, with markings similar to that of the Golden Eonymus? There is a variety growing near here, which is termed golden, but the majority of the leaves are altogether green, and the others cream-coloured and striped. It is almost worthless. Is it the variety named *Hedera aurea variegata*? if so, an improvement on it would be desirable.—A. BOYD, *Slany Park, Wicklow*. [The merits of any particular variety of variegated Ivy can scarcely be determined by its habit and general appearance in any given place. The variety mentioned by Mr. Boyd is most likely *Hedera Helix aurea*, which is very good in some soils, but not so constant as *H. Helix aurea spectabilis*. The nearest approach in appearance to a Golden Eonymus is *H. Helix arborescens aurea*.—E. G. HENDERSON & SON.]

Effects of Trees on Temperature.—M. Faunal has communicated to the French Academy the results of a series of observations on the comparative influence of leafy and resinous trees on the temperature and ozonometric condition of a locality. Observations at an altitude of 50 ft. from the ground showed that trees of all kinds, in the processes of assimilation and transportation, produce a lowering of the temperature in the surrounding air; but this cooling effect is more marked with resinous trees than with others. Under the former the proportion of ozone appears to be uniformly less than at equal altitudes in the open ground around.

Hymenanthera crassifolia.

LETTUCES ALL THE YEAR ROUND.

To maintain a never-failing supply of good Lettuces, irrespective of variability and irregularity of season, is a somewhat severe test of the resources and ingenuity of the cultivator; in fact, he who can furnish a well-grown, juicy, crisp Lettuce every day in the year will not need to give a much better proof of capability in this branch of gardening. In moist, dripping summers the culture of such plants as the Lettuce is comparatively easy, and the required supply will come on in desired succession; but there are times, such as during the past summer, for instance, when ordinary calculations are entirely at fault. Hot, dry weather sets in suddenly, and as it often succeeds a showery period, it finds vegetation in a tender state, and is consequently apt to produce rather disastrous effects. Whole patches of plants will bolt, others become suddenly checked and crippled in their growth, and do not arrive at half their proper size; young plants do not progress favourably, and sowings do not start into growth as anticipated. The effect of this is that awkward blanks occur, and the supply will either quite fail or will be of the scantiest and poorest description. In places where special arrangements have been made for a copious supply of water, this inconvenience will not of course be experienced; but where such is not the case, and labour is at all short, a considerable amount of forethought and judgment must be brought to bear upon the culture of the Lettuce. For let it be understood I speak now of the production of a Lettuce firm, juicy, and succulent, such as may be bought in Parisian markets in the hottest weather in summer, and without which, as the French so well know, no salad worth eating can be made. A very rich, free soil, combined with copious and constant waterings, and great solar heat, enables the French cultivator to raise a large amount of produce from a small space. Lettuces, Radishes, and all kinds of salading grown under such circumstances are tender and full of juice; flabby, tough Lettuces, and hard, stringy Radishes are almost unknown in the Parisian markets.

In order to secure a supply of Lettuces all through the year, sowings must be made at certain periods, which periods, as well as the amount of seed sown, must be regulated by the time of year and requirements of the household. One of the most important points to be kept in remembrance is that a delay of a few days in the sowing of the seed will sometimes occasion a serious break in the supply: this is the more likely to occur in the summer months. About the beginning of February a sowing of the Paris White Cos should be made in gentle heat. The seed should be sown in shallow boxes, and, when up, removed to a cool frame, and if the young plants can be pricked out while there into a free soil, it will assist their development. This sowing will be found to be indispensable, as it comes in between the autumn-sown batch and the first outdoor sowing. Preparations should be made during this month, too, for planting out those which have passed the winter in cold frames; for this purpose as sheltered and warm a situation as possible should be chosen; a south border, for instance, where protection from the cold easterly winds which sometimes prevail in March and April is afforded to the young growth. If the soil be at all of a stiff, tenacious character, it should be thrown up into ridges, leaving the lumps as large as possible, and remain so for a time. Nothing benefits soils of this description so much as exposure in this manner to the air and frost, and it is indispensable for the quick growth of all tender vegetables that the soil in which they are planted should be of a very free nature. Lighter soils will not require this attention—digging over two or three times, choosing either frosty or dry, windy weather, will suffice. Old decomposed manure should be used, and be dug in with a four-tined fork and thoroughly broken and incorporated with the soil. Planting-out will depend upon the weather; it is as well not to commence this operation too early, for hard, inclement weather immediately succeeding necessitates their being protected, and they are apt to receive a check, which considerably retards their subsequent growth. The beginning of March will be found early enough, and if the plants be a moderate size, and have been kept dwarf and hardy they will be pretty well established before being called upon to make quick growth. The best way of planting them

I consider to be in drills, which can be easily drawn in the free, loose soil with a broad hoe. It sometimes happens that we have a dry season during April and May, when a watering or two becomes necessary, and when thus planted the water is more easily given, and less suffices—always important considerations. This batch of plants generally succeeds well and attains a good size, the above-named months being the most favourable time of year for them, and they are less liable to bolt. If, therefore, enough have been put out, they will afford a sufficient supply until those sown in February are ready. These latter, which will have commenced growing, and then been properly hardened off, can be planted out in April, being well watered, in the event of dry weather, until well established. At the beginning of March a sowing should be made in the open ground in a dry, sheltered spot; these should only be thinned out, leaving a portion at growing distances; these latter will be somewhat earlier than the transplanted ones in arriving at maturity. About the middle and latter end of the month other sowings should be made in the same manner, transplanting a portion, and leaving the rest for further growth. Any of the Cabbage varieties and White Cos may now be sown. By frequently sowing and employing various kinds there will be no danger of a deficiency in the supply. This method will apply to the next two months, as it is seldom that the weather is very hot and trying before June. During March, April, and May seed comes up well, and young plants thrive and come to maturity in a tolerably equable manner. The weather must, however, entirely regulate operations in this respect. If, therefore, either April or May should be dry, the water-pot must not be spared. The principal aim should be to keep the crop growing, not allowing a check to take place, for, when once that occurs, time is lost, size is sacrificed, and the quality is always inferior. This especially applies to leaves half or three parts grown, as such can never be made to regain their pristine crispness and juiciness if once they suffer from want of moisture. From a thoroughly well-grown Lettuce there is not much waste, but when indifferently grown the half, perhaps, of each head is sacrificed; it will therefore be easily seen how necessary good culture is for those who wish to economise time and labour. I would therefore again forcibly recommend the utmost attention to be paid to the preparation and enriching of the soil together with timely watering, without which no one can think of succeeding in Lettuce culture with any degree of certainty. June, July, and August are, as a rule, the most trying months for all that relates to salad vegetable cultivation. With the early crops situations are chosen which appear best adapted to their favourable growth. It is not always easy to localise crops, but when we arrive at the fair weather period this can in many cases be very well managed, and it will be found a better plan to save a piece of ground especially for this purpose, so that the successional sowings may be kept together. In all respects this is preferable to having them scattered about indiscriminately; the soil can be better prepared, and the relative size and proportionate progress of the successional sowings can be seen at a glance; one of the main things, too, is secured, viz., a ready facility for sowing the seed. When a piece of ground has to be found and prepared as required, it often happens that the work is delayed. It would be well, if it could be so arranged, that the Lettuce quarter were in the immediate vicinity of the water supply, but if this cannot be managed, they may be kept together, and watering will be much facilitated. During June and July seed should be sown about every ten days, and about August 10 there should be one sowing for autumn use. The last two or three sowings should be made in as exposed a situation as possible, as they will require all the light and sun they can get during the waning days of September and early part of October. Much labour may be saved if mulching be practised for the summer crops; in fact, without this aid it would be almost useless to attempt to grow good Lettuces in some seasons; manure is best if it can be had, if not, short Grass or litter of any kind. Although mulching is recognised as beneficial, and much is continually being urged in its favour, it has not yet been carried out so extensively in this country, and that more especially with respect to quick-growing crops, as it ought to be; indeed, so valuable is its agency, that in continued dry weather, and under a burning sun I have seen crops gathered in such perfection that would

almost appear incredible. Success in the growth of Lettuces during the summer months will therefore mainly consist in a deep, rich, free soil, and frequently in sowing with timely and thorough watering in hot weather and mulching.

And now a word as to sowing. I have found that the best way is to sow in drills, putting in a sufficient quantity of seed to ensure a plant and thin out to about 1 ft. apart in time to prevent them drawing and becoming weakly, and mulch when they have five or six fair-sized leaves. It is not advisable to put on the mulch too early, for if the weather be moist, it will harbour slugs, which will clear off in the seedling state the whole sowing in one or two nights. This disaster is in any case liable to occur, if preventive means be not adopted; this will consist in dressing the surface soil around them with soot and lime, which labour should never be grudged, as two purposes will thereby be served, viz., vermin held in check, and the crop manured. It is as well, too, in the earlier stages of growth to give the surface occasionally a stirring with the hoe; the benefit of this operation is too well known to need enforcing. It sometimes occurs in summer that when seed is on the point of germinating, a scorching day comes which dries up the seed before it is fairly through, which results in an entire loss of that sowing, or the ground being in a very dry, parched condition when sown, it refuses to come up at all, thus upsetting all calculation. If the seed has commenced to swell and then becomes dry, it will be very uncertain about its germination—it will either not come up at all, or will only come when the next period of wet weather arrives. This inconvenience is, I believe, of frequent occurrence, and to it may be attributed the want of salading which is so often felt towards the latter end of July and during August and September; it is, however, easy of remedy. If the ground be very dry, draw a drill quite 2 in. deep, thoroughly moisten it and sow the seed therein, immediately making the surface firm, give a watering, and cover the whole with some litter or old mats. The seed should be, however, previously prepared by soaking it in water some twenty-four hours before using; drain off the water and mix with it some dry sand, by which means it can be more conveniently sown. Attention must be paid to the first development, removing the covering upon the first appearance of the plants. If the weather be very hot at this time, it is as well to shade a little during the hottest portion of the day with a small quantity of Fern thinly scattered on them to keep off the scorching rays of the sun, but not sufficient to exclude the light. This may to many appear somewhat tedious, but it is absolutely necessary to ensure germination. About August 20, and then again towards the latter end of the month, some of the Black-seeded Bath Cos, in addition to the White Cos, should be sown, the former to be sheltered in frames, some portion to come in early in spring, and the rest to be planted out in March; again, about September 10 another sowing of Brown Cos may be made. Be sure to make these sowings in an open, sunny situation, and tolerably thin, as it is important that they should come dwarf and hardy. In September preparations must be made for insuring the winter supply. Frames, with an aspect fronting the south, are preferable for this purpose; they should lie as dry as possible, and the lights should be in good repair, to prevent damage from drip, damp being the greatest enemy to be guarded against at this season. Some of the White Cos or Cabbage kinds, that were sown in August, should then be planted, taking them up with a good ball, and watering them copiously if the weather be at all dry. The lights should only be put on if very sharp frosts occur until the middle of October; after that time they must be kept gently growing, giving plenty of air in mild weather, and covering up in case of frost, and they will then be ready for cutting about Christmas. Other frames should be planted successively during October or November, which, being treated in the same manner, will furnish a supply all through the winter and early spring. If there be any signs of the supply running out in the early part of the year, a gentle hotbed may be made up, and some of the most forward plants put thereon; some beautifully crisp Lettuce will be obtained in this way. Those who have a stock of the large hand-glasses or cloches will find them admirable for the winter-growth of Lettuce, they being drip-proof, and can be easily covered up with Fern or litter of some kind in hard weather;

those having orchard-houses may utilize a portion for this purpose. If some boxes be planted in September they can, when bad weather arrives, be just placed therein, and their contents will improve in quality. Early in November the Brown Cos should be pricked out in frames to be there wintered. The lights are only to be put on in severe weather, as the object is to keep them as sturdy and hardy as possible. If there be a scarcity of frame room, some may be pricked out in the open ground, choosing a warm, dry spot, and making the soil somewhat sloping towards the south. Prick out the plants thereon about 3 in. or 4 in. apart, fixing the soil firm and smooth around them. A few hoops can be bent over so that in very hard weather a mat can be thrown on, or a row may be planted close to the wall on a warm border, and if the winter be not too severe they will survive and come in early in the spring. All those planted in frames should have careful supervision during the winter, giving plenty of air and removing regularly all decaying leaves. The surface, too, should be dredged occasionally with dry mould or ashes, a supply of which must be laid in for that purpose. Slugs and snails must be looked sharply after, as they will, if undisturbed, commit sad havoc; some soot sprinkled on the surface of the soil will keep them in check. As before mentioned, the demand must regulate the operations of the grower; if much salading be required in the winter, a good breadth of the Brown Cos should be sown in August, which should be removed, before very wet or hard weather sets in, to where they can be sheltered from wet and frost. Pits covered with shutters made rainproof answer the purpose, if frames cannot be had; they may, even in default of better convenience, be stored away in a dry, airy shed. These, of course, cannot be expected to equal in quality those cut in a growing condition: but they afford a greater supply than would otherwise be obtainable at that season; besides, the growing stock in the frames gets thereby a longer season of growth.

JOHN CORNHILL.

Byfleet.

FRUIT AND VEGETABLE CROPS OF FRANCE.

DOCUMENTS lately published by M. Joly, and based for the most part on M. Hussion's work on the "Food-Supply of Paris" and the Report of the Paris Chamber of Commerce on the "State of Labour in France," supply the following particulars:—In 1872, in the Department of the Seine alone, there were 24,803 cultivators of different kinds, who together produced nearly £1,100,000 worth of fruit, vegetables, and flowers. There were in the Department 427 gardens, covering an area of over 200 acres, of which 2,500,000 square ft. were under glass. The quarries used for Mushroom growing had an area of nearly 20 acres, and consumed £2200 worth of manure, the value of the year's crop being £72,000. On the market of the Halles Centrales were sold whole during the same year:—Choice fruit, 790 tons, at an average of 60c. per lb.; ordinary fruit, 3186 tons, at 37c. per lb.; choice vegetables, 668 tons, at 43c. per lb.; ordinary vegetables, 11,600 tons, at 15c. per lb. The gross amount realized by the sales was over £130,000. The total quantity of fruit brought into Paris during the year is estimated by M. Hussion at nearly 62,000 tons. Fresh vegetables from the south of France amounted to 19,700 tons; those from the neighbourhood of Paris, to 343,620 tons; dried vegetables and herbs, to 16,735 tons.

The subjoined Table, prepared from data collected by the Administration des Douanes, shows the quantities of garden produce exported from France during the year 1874:—

Oranges and Lemons	3,257 tons.
Fruit, fresh	42,700 "
Do., dried and flattened	14,000 "
Do., preserved, conserves, &c.	2,135 "
Almonds, Filberts, and Walnuts...	15,000 "
Vegetables, dried	24,161 "
Chestnuts	6,300 "
Potatoes	173,144 "
Total	280,698 tons.

[Here no mention is made of the quantities of fresh vegetables exported from France.]

Seedling Camellias.—I shall be grateful to any reader of THE GARDEN who would tell me the best treatment (as to transplanting soil, &c.) for seedling Camellias from the time they get their second leaves, when my seedlings are nearly sure to be spotted, and then gradually perish.—SOUTH ITALY.

NOTES ON THE FLORA OF THE PYRENEES.

By GEORGE MAW, F.G.S., F.L.S., &c.

As a mountain district the Pyrenees form a contrast to the complicated mass of the Alps, and may be described in general terms as a huge escarpment forming the edge of the great tableland of Spain, which has an average level of about 2000 ft. above that of the French plain on the northern side. Between the high-level Spanish plain and the low-level French plain, central patches of eruptive rocks determine the line of the main chain, from which, amidst a multitude of east and west faults and dislocations, the mesozoic and tertiary beds dip away north and south, those on the north side bending up suddenly towards the original line of upheaval, whilst on the Spanish side they spread away as a plateau over the plains of Navarre, Aragon, and Catalonia as a wavy expanse of escarpments facing the chain. On the north side, the high ground flanking the main mass of the range has been channelled by the agency of sub-aërial denudation into a multitude of beautiful gorges and valleys, many of which are remarkable for their sudden turnings; gravitation of the waterflow from the high chain has induced a general south and north direction, whilst the trend of the strata and lines of faulting have acted in conflict, and here and there suddenly diverted the original lines of waterflow east and west for a few miles, when again gravitation has had its way, suddenly bending the streams back in a northerly direction.

One of the most characteristic features of the northern flanks of the Pyrenees is the series of beautiful mountain masses of from 5000 ft. to 8000 ft. high that occur at the termination of the ridges separating the lateral valleys. The accompanying view of the Pic du Midi may be taken as typical of more than a dozen similar mountains that face the plain of Languedoc at the junction of the streams flowing from the central ridge; higher up, after passing through the lateral gorges, the valleys for the most part terminate against the central mass of the chain in huge amphitheatres or "cirques," which form noble features in the aspect of the higher parts of the range.

Pine forests throughout the chain enrich the beautiful scenery. *Pinus maritima* and *P. Pinæ* occurring at low levels near the sea at the eastern and western extremities, and *P. halepensis* near the Mediterranean in the Eastern Pyrenees. *Abies excelsa*, in the lower parts of the forests, *Pinus sylvestris* and *P. pectinata* in the middle zone, *Pinus uncinata* at high levels up to 7000 ft., and *Pinus Laricio* sparingly in the Central Pyrenees.

A careful comparison of the alpine and pyrenean floras presents many points of interest in the geographical distribution of species: the larger proportion of species are common to the Alps and Pyrenees, whilst a large minority are special to the latter.

Primulas are but poorly represented as regards the number of species—*P. farinosa*, *P. viscosa*, *P. latifolia*, *P. Auricula*, *P. integrifolia*, *P. officinalis*, *P. elatior*, and *P. intricata*, complete the list; and the last, which is but a form of the alpine *P. suaveolens*, is the only species not found in the Alps. The allied genus *Androsace* presents a curious contrast, for nearly half the pyrenean species, including *A. pyrenaica*, *cylindrica*, and *imbricata* are absent from the Alps; and all the commoner alpine species, except *carnea* and *Vitaliana*, are absent from the Pyrenees.

Of Gentians the yellow *Gentiana Burseri* and *G. pyrenaica* may be named as special pyrenean species, and most of the widely-distributed species of the Alps also occur in the Pyrenees.

The distribution of Saxifrages in the Pyrenees presents some points of interest. *S. Clusii*, which is common to the Pyrenees and the Tyrol, is missed in Switzerland; *ajugæfolia*, *aquatica*, *geranioides obscura*, *pentadactylis*, *longifolia* (Lapp), *arctioides*, and *calyciflora*, are peculiar to the Pyrenees, the two last have interbred largely, and produced several curious hybrids. The Western Pyrenees and their western extension to the Asturias, are, with the south-west of Ireland, the head-quarters of the Robertsonian Saxifrages, a few isolated forms of which also occur in the Alps of Tyrol and Switzerland, and it is an interesting fact that several other Hibernian species, notably *Menziesia polifolia*, which occurs so

profusely in Connemara, are also associated with the Robertsonian Saxifrages in the Western Pyrenees and the Asturias; almost the only continental habitats of the Scotch *Menziesia cœrulea* are in the vicinity of Luchon, Central Pyrenees.

Many of the commonest plants of the Pyrenees which form marked features in the flora, are peculiar to the district. *Tenerium pyrenaicum* is abundant everywhere; *Hyacinthus amethystinus* in the moist meadows, and *Antirrhinum semper-virens* and *Ramondia pyrenaica* on the rocks, conspicuously adorn the valleys between Lourdes and Gèdres, and *Viola cornuta* forms a beautiful feature in the meadows before the hay harvest in the early summer.

A remarkable instance of extreme geographical isolation occurs in *Dioscorea pyrenaica*, a miniature Yam, found in one or two of the higher valleys of the Pyrenees, though belonging to a genus which is both extra-european and tropical.

Amongst the many highly ornamental alpine plants of the chain, *Aquilegia pyrenaica* takes a prominent place: cultivated specimens give but a faint idea of its extreme beauty in its native habitats, which is often set off by association with golden masses of *Hypericum nummularium* on the higher rocks. *Saponaria cœspitosa*, with its brilliant cushions of large rosy flowers, *Adonis pyrenaica*, *Arenaria purpurascens*, *Arenaria tetraquetra*, *Globularia nana*, *Geranium cinereum*, and *Ranunculus amplexicaulis* also form conspicuous features in the pyrenean flora.

Of bulbous plants *Iris xiphoides* is one of the most abundant species in the higher valleys, often associated with the Dog's-Tooth Violet and *Fritillaria pyrenaica*, the only pyrenean Fritillary. There are but two species of *Crocus* in the Pyrenees. *C. vernus* occurs less abundantly than in the Alps, and the beautiful autumn-flowering *C. nudiflorus* has its headquarters here, extending also westward to Central Spain, and eastward towards Central France, but no other Spanish *Crocus* reaches so far east as the chain.

Of the three species of pyrenean Lilies, *Lilium Martagon* and *L. bulbiferum* are common to the Alps and Pyrenees. *L. Martagon* is most abundant, and extends as far west as Portugal; *L. bulbiferum* only occurs here and there sparingly, and appears as a sort of outlier from its district, the lower regions of the Alps. *L. pyrenaicum*, in its west-european distribution, is strictly limited to the Pyrenean chain, as it can scarcely be looked upon otherwise than as an alien in Devonshire; it is found nowhere in the Swiss or Eastern Alps, but after bridging the whole of France, Switzerland, and the Tyrol, it curiously reappears in a slightly modified form as *Lilium albanicum* in Eastern Europe. The Pyrenean district is the north-eastern starting point from which the *Corbulariæ* extend westward into Spain and Portugal, and they are largely represented in the Asturian prolongation of the Pyrenees. The Pyrenees and the Asturias are also the head-quarters of the Ajax group of *Narcissi*. *Narcissus muticus*, a form closely allied to *Pseudo-Narcissus*, is abundant about Gavarnie and the sub-alpine districts of the Pyrenees.

The limits of a short paper are insufficient to deal fully with the many interesting points connected with the geographical relations of the special plants of the Pyrenees and the distribution of its rich flora: to the plant collector there are few districts so tempting or so easily accessible. Luchon, in the heart of the Pyrenees, can now be reached direct from Paris by rail in twenty-five hours, and is a capital centre for botanical exploration. The Val d'Esquerry, within a short ride, and the Spanish side of the Porte de Venasque, a rather longer excursion, abound in species which the cultivator of alpine plants will delight to collect. Gavarnie is also readily reached by way of Lourdes and Luz, and has the advantage over Luchon in its altitude of 4400 ft. A new hotel near the Cirque de Gavarnie now offers additional accommodation to that at the homely but comfortable little inn lower down, which botanical explorers have for many years made their head-quarters. Those who contemplate a botanical tour in the Pyrenees, should consult Phillippe's "Flore des Pyrénées," Packer's "Guide to the Pyrenees" (full of botanical information), Wilkomm and Lange's "Prodromus Floræ Hispaniæ," Grenier and Godron's "Flore de France," Bentham's "Catalogue des Plantes Indigènes des Pyrénées," and "Verlot's Guide du Botaniste Herborisant."

VEGETATION OF THE MIDDLE PEAK OF OSSAU, PYRENEES.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Sarracenias.—I know of 10 plants more interesting than these; they should be grown by all amateurs who can appreciate beauty and singularity of form. They are easy enough to manage if a few essentials to their well-being be kept in view. The want of success often experienced with these plants is generally attributable to the mistake made in treating them indiscriminately with the ordinary occupants of the stove, not only in the amount of heat to which they are subjected, but also as to water and soil. The advice often given as to their requirements has been such as to induce those not experienced in their cultivation to keep them in too great heat, especially in the winter time, which has the effect of preventing their getting the rest they require; it also induces weak, soft, elongated growth, that stops many of the leaves being fully developed into their wonted pitcher-like form, a condition which robs them of their characteristic singularity. The different species will succeed well with similar treatment as to soil, moisture, heat, and air. From the middle of November till the end of February they should have a temperature of 50° by night and 5° more in the day; after this time increase 5° night and day; during the spring and summer it may run from 60° to 70° in the night and from 75° to 80° by day, according to the state of the weather. Whether they seem to need it or not, each year in February get all the soil gently away from them, re-potting them in a fresh compost consisting of equal parts of the best fibrous peat with all the earthy matter abstracted, and chopped Sphagnum liberally mixed with corks or charcoal broken moderately fine, adding to the whole a good sprinkling of sand. If they be potted late in the season, the pitchers often come crippled. *S. Drummondii alba* and *S. Drummondii rubra* are exceptions to the others in the time of potting, as about July, when their spring growth is finished, is the best season to move them. The pots should be one-third filled with corks; the creeping stems must be kept just above the soil. They must be watered every day from the time they begin to grow freely until autumn, and twice a week in winter. All the varieties of *Sarracenia*, except *S. purpurea*, must not be syringed, as it renders them soft. They should have a shelf of unplanned wood to stand on; this will hold moisture, and it ought to be damped two or three times every day during the time the plants are growing; let them have a place at the south side of the house near the glass, or else elevated till they nearly touch the roof; they should occupy a moist corner, and though they like a moderate quantity of air, it ought not to be admitted close to them. They must not be stood in pans, as their roots are liable to rot when so treated. A very thin shade is necessary when the sun is on them. The flowers ought to be nipped out directly they appear, at any rate whilst the plants are small, as they weaken them. All the flower-stems that are thrown up divide the crowns that produce them into two, by this means they increase, but until they get a good size they ought not to be separate. Scale is very troublesome to them, and it will seriously injure them if allowed to remain; they are also subject to green fly, and above all, thrips; these latter especially get under the rim of the mouth of the pitchers, and if not soon destroyed, the pitchers will be ruined before they have lasted half their proper time. With plants newly imported the almost general mistake is to keep them too hot at first, the result of which is to cause them to make leaf-growth without any corresponding root-action, the latter very often never making any progress during the first summer; when this is the case, they almost always die the ensuing winter. As soon as the plants arrive, they should at once be placed in pots that will only just hold their roots with a moderate quantity of soil. Keep moist, but if they come in the autumn, they should not be subjected through the winter to more than from 46° to 50° in the night, increasing the heat a little as the spring advances, and in the summer give them no warmer treatment than an intermediate-house will afford.

Azaleas.—Any of these that have been forced for the purpose of flowering early should, directly they have ceased blooming, be placed where they will begin to grow; if put now in a cold house the growth, which the heat to which they have been subjected to bring them into flower will have excited, will receive a check; if this occur, the plants will be injured. Be very careful to see whether there are any thrips upon them; should these be found, give a good washing with Tobacco-water. This is not only necessary for the well-being of the Azaleas, but also on account of other plants, for if the insects be only few in number, they will quickly spread to every subject in the house that they will live upon; the safest plan is to wash, whether any thrips are discovered or not. It sometimes happens that Azaleas that occupy pots as large as desirable get into a weak state through the soil becoming exhausted. When in this condition they are generally thrown away; this need not be done, as in a

couple of years they can be brought into a thoroughly satisfactory state. The present is a good time to begin; allow the soil to become rather dry, but not so much so that the plants would need watering for several days; then cut them well into the old wood, reducing them to about half the size they were before they were operated upon. Give them a good cleansing if they have had any insects on them, and put them in a moist heat of about 60° by night. Syringe overhead once or twice a day, but the soil must not be permitted to become too wet. If all go well, they will break in the course of four or five weeks.

Pits and Frames.—The soil intended for Cucumber beds ought to be put in an airy, open shed, and turned over often so as to dry it and bring it into a fit state for use; if too wet when put on the beds, it renders the young leaves so tender by the vapour it causes as to make them very liable to injury from the sun. Give abundance of air to the occupants of frames on mild days, more particularly Lettuces and Cauliflowers, taking the lights off them entirely, so as to prevent their becoming weak.

Kitchen Garden.—Ground at the foot of a south wall should be prepared for Potatoes by digging it over, and, if the soil be poor, adding some manure; by doing this at once in a week or two it will become drier, and be in a better condition for planting than at present.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

February 26.—Making Asparagus land ready for sowing. Getting land ready for Seakale planting. Sowing another batch of French Beans, and placing them where they can be kept at about 55° at night. Potting *Gladiali*, *Chrysanthemums*, *Stachys lanata*, and *Calamint*, and pricking off young plants of *Feverfew* and *Lobelia*. Beginning to box off *Salvia fulgens*. Putting in cuttings of *Justicia*, *Heliotropes*, *Coleus*, *Achyranthes*, *Bouvardias*, *Thyracanthus rutilans*, and scented-leaved *Pelargoniums*. Starting some *Achimenes*. Putting a slight shading over *Cinerarias* during bright days. Tying up some Lettuces under cases to blanch. Watering inside borders of Muscat and Black Hamburgh-house, Rose pits, and Mushroom bed. Salting all Mossy pathways. Thinning first Muscat Grapes; also Strawberry blossoms. Clipping Ivy and cutting out dead Laurels. Giving a little soot to all Strawberry plants in bloom and that have set their fruit. Keeping East India and *Dendrobium*-houses at a temperature of 70° by day and 65° at night with fire-heat. Shutting off fire-heat from *Lycaste*-house at 60°. Starting Muscat and Hamburgh-houses at 53° at night and 58° by day with fire-heat.

Feb. 27.—Putting some *Gloire de Dijon* Roses against a south wall, plunging the pots, and nailing the shoots to the wall for very early out-door flowers. Planting out Cauliflowers between dwarf Peas. Beginning to plant Lapstone Kidney Potatoes. Finishing planting Globe Artichokes. Staking the earliest Peas. Covering more Peas with Asparagus tops to keep them from sparrows. Taking up all plants of Osborn's Winter Broccoli that are showing and placing them under protection. Putting some new soil and manure to Cherry trees. Mannering Strawberry and Asparagus beds. Keeping Rose-house from 50° to 55° at night.

Feb. 28.—Sowing Radishes under the protection of a Peach wall; sowing also early Dutch Turnips, and six lights of early Dutch Forcing Carrots and Radishes along with them. Potting plants of *Dielytra* for forcing, 200 white Pinks for forcing, and *Tropaeolum caucariense*. Pricking off *Capsicums*. Putting in cuttings of *Plumbago*, *Scarlet Pelargoniums*, and *Willow*, the latter to furnish flower-sticks. Planting some spare hand-glass Cauliflower plants under cases, and a few potted Potatoes under protectors. Putting some Musk into heat, and also the last batch of Rhubarb. Taking young plants of *Centaurea* and *Oxalis* out of heat and putting them into cold pit. Wrapping *Salvias* in Moss, and putting them in boxes in heat in a Vinery. Topping Turnips and covering them up behind a wall in order to try to keep them as late as possible. Watering third Peach-house, giving a truck-load to a tree. Earthing-up third pit of Potatoes. Pruning *Lapagerias*. Rolling walks and Grass lawns.

March 1.—Potting *Heliotropes* and cuttings of stove plants. Shifting *Schizanthuses* into larger pots, also *Veronica Andersoni variegata*. Potting-off spring-struck *Alternantheras*, *Nepeta*, and *Oxalis*; likewise another lot of French Beans, and placing them in second Hamburgh-house. Staking out and re-potting previous cut-

down scented Verbenas. Sowing Rhodanthe and various sorts of Melons; also some Mignonette under the protection of the Orchid-house wall; and a little Chervil, covering the seed with ashes. Planting Potatoes, Shallots, and Garlic; also some Watercress roots in pond. Pricking off some Red and White Celery. Potting East Indian Orchids, using Sphagnum. Putting *Cattleya superba* on blocks, and placing them in East India-house. Putting in cuttings of *Pelargoniums*, *Iresines*, *Mesembryanthemums*, *Crystal Palace Nasturtiums*, and *Carnations*, the last under bell-glasses on a slight bottom-heat in hotbed frame. Top-dressing planted-out *Gardenias* with leaves. Putting in another batch of Strawberries for forcing; also another crop of *Asparagus* roots. Digging borders for *Carnations* and *Gladioli*; also *Celery* land for Peas, and dressing the Mint bed.

March 2.—Potting Ghent Azaleas and plunging them; also *Deutzias*. Sowing Tree Mignonette in small pots in heat; also sowing Gourds, Beans, Champion of England and Nonpareil Peas, Spinach, Early Dutch Turnip, Incomparable White Celery, Early French Horn Carrots, and Radishes in frames. Planting *Schizostylis coccinea*; also Horseradish in trenches. Pricking off Sweet Basil, Marjoram, and seedling Tomatoes. Shifting Disas, *Lælia majalis*, and *Epidendrum erubescens* and putting them into greenhouses. Putting in cuttings of Purple King Verbeena, Anne Boleyn Pink, and more *Dablias*; also *Monochæstum ensiferum*, and *Thyracanthus rutilans*. Putting in Chicory to blanch; also another batch of Sea-kale. Digging vacant borders, preparing land for Cabbages, and preparing a bed for *Carnations*. Arranging and cleaning old *Pelargoniums* in pits. Putting pots over Seakale, and covering them up with soil for late cutting. Preparing frames on leaf-beds for young spring-sown Lettuce plants. Spawning Mushroom-bed. Starting Peach-cases at 45° to 50° at night, 55° by day with fire-heat, to 85° by sun-heat with air on.

March 3.—Potting Heaths in peat; also *Ferns* in loam, sand, peat, and leaf-mould. Potting off rooted Vine eyes, and boxing and potting off *Salvias*; also *Pelargoniums*, *Petunias*, and *Mimulus* for flowering in pots. Shaking out and re-potting old *Fuchsias*. Sowing Onions and Parsley. Planting four frames of Potatoes. Basketing plants of *Vanda cœrulea*. Mossing *Dendrobiums* on blocks, and re-blocking those that require it. Nailing and arranging creepers on front of house. Clearing away straw from *Calceolaria* pit. Tying and stopping third Vines. Clipping Box edgings. Thinning all Grapes that require it, leaving seven bunches to a rod on pot Vines. Disbudding early Peach trees a little where the shoots are very thick. Looking over fruit room and removing all decayed fruit. Cleaning Herb beds and Rhubarb plot. Burning up rubbish.

Orchids.

Many Orchids will now be found in a sufficiently advanced state of growth to admit of being either re-potted or top-dressed, for any which are well-rooted and healthy will only need the old material removed from between the roots and its place supplied with fresh compost. Unhealthy plants having few roots should be turned out of their pots, the decayed portions of the roots cut away, the foliage and pseudo-bulbs thoroughly cleaned, and the plants re-potted in comparatively small pots. In the case of unthrifty specimens of this kind it is better to place them after re-potting in a group by themselves in the Orchid-house, in order that they may be better attended to than the more robust-growing plants. Whenever new pots are selected for potting Orchids care should be taken that they are soaked in water for some hours, and afterwards drained until they are almost dry before using them; when old pots are employed, they should be perfectly clean within and without; the crocks also should be thoroughly cleaned and exposed to the air for a time before they are made use of. A supply of fresh, living Sphagnum Moss should at once be obtained, and stowed away in a cool, airy shed, so that it may be preserved in a living state throughout the whole of the spring. Before putting the Sphagnum away it should be carefully picked over, removing all rushes and leaves, and taking out all weeds, but the Moss itself should not be shaken about more than is necessary, as it keeps better and fresher if allowed to remain in small flakes as gathered; it also grows better, and consequently keeps good longer, when used in this form. It is a bad practice to shred up the Sphagnum and mix it with peat for Orchids, even where a mixture of peat and Moss is necessary. It is better, in potting a plant requiring such a compost, to use the small lumps of peat and Sphagnum as gathered alternately; the Moss will then grow rapidly, whereas, if torn up and mixed with the peat, it takes a long time to start into growth, and, in the case of summer-potted plants, it frequently dies, and the plant loses the benefit of that gentle moisture which is so conducive to its well-being.—JAMES O'BRIEN.

THE FRUIT GARDEN.

PRUNING PEAR TREES.

The first point of importance in regard to Pear trees is when to prune them. Prune in winter or very early in the spring, and the trees are forced into early blooming; prune late, and there is a considerable loss of vital strength by the growth already made and cut away on the extremities of the shoots; in fact, the time of pruning compels the cultivator to make a choice between the vigour of his trees and their fruitfulness; and the fruit, being the primary object, of course will unhesitatingly be awarded the preference. Some prune so persistently and so late in summer that little or no pruning is possible in the winter or spring months. This practice is more dangerous than early autumnal or winter pruning. In our climate it is unwise, as a rule, to prune in summer more than once. Were sunshine and warmth perpetual and constant in quantities and conditions instead of being erratic and inconstant, then persistent summer stopping or pruning might be more rationally carried out. Hence with fruit trees under heated glass structures the cultivator may pinch, stop, or prune Pear and other fruit trees as he pleases; but the policy or wisdom of doing so may reasonably be challenged on vital and natural grounds. In the open air in our climate all such unnatural and unclimatical (to coin an expressive phrase) summer prunings are vicious in theory and bad in practice. One summer pruning in June is all to which pyramidal, cordon, espalier, or other Pears should be subjected in the open air in our climate; neither must that single pruning be too close, or else the breastwood had better be left unpruned. The result of cutting into one or two eyes, and the breaking of those eyes is a late and worthless growth, which will render the formation of fruit-buds impossible, and make the tree quite tender and totally unfit to face the cold winds and frosts of winter. Judicious summer pruning exposes the remaining buds to the best solar or other influences for their conversion into fruit-buds. The questions have frequently been raised, is such conversion possible, and at what stage in the development of buds do such changes occur? Has the cultivator the power of electing where a fruit-bud shall be placed, and where a wood-bud? Are such vital points in fruit-growing amenable to cultural and solar conditions—as queen bees, for example, are an affair of royal cells? Multiply the latter and you multiply queen bees, increase the light and heat on Pear-buds at the base of the breastwood and you multiply fruit-buds. That, however, is the knotty problem on which the success of summer pruning may be said to be based. Winter or spring pruning has no power to convert anything. It may hasten or retard the development of buds, and thus so far create or hinder undue competition with other buds, whether of wood or fruit.

The time of the opening of flower-buds is, therefore, largely in the pruner's power, as also the conditions under which buds shall grow into fruit or wood; and these, properly understood, are wonderful powers indeed. Prune your trees in November, and your Pears will be in flower in February or March; prune them in February or March, they may not be in bloom till April or May. By losing a month, a week, a day in the time of flowering, the chances of a crop are greatly increased. In our springs the later the flowers the more sure the crop; and as late pruning results in late flowering, the later we prune the more surely does fruitfulness follow, which assertion may be safely accepted as absolute truth, confirmed by observations and experience extending over a quarter of a century. It may be safely carried out in practice, even to the extent of allowing the fruit to set and the leaves to be fully expanded, before we prune Pears at all or reduce the breastwood with its several buds left at its base after summer-pruning to the one or more buds left after the winter or spring pruning. The Pear seldom bleeds much, even if pruned after growth has begun; it does not bleed at all if not pruned till the leaves are expanded; hence the later we prune, as far as the chances of a crop and the well-being of the trees are concerned, the better. Of course, too, in pruning late the cultivator has a greater elective power in leaving the best-positioned wood-buds and the most perfectly set and formed fruit. For, assuming

that the pruning of Pears in the open air may be put off till May, not only with safety but with advantage, he may then prune or thin off fruits as well as wood-buds at one and the same operation, and only leave the best of both intact. Undoubtedly there is a loss of vital force in such late prunings; but that is of little moment. Every pruning, be it early or late, represents a loss of force, and perhaps when our knowledge of plant life is more advanced, and our cultural arts reach a higher degree of perfection than at the present time, pruning in the style and sense in which it is now indulged may become a thing of the past. D. T. FISH.

Early Melons.—Considerable difficulty often occurs as regards ripening off first crops of Melons by a certain time; in fact, a classification of the various sorts—into early, midseason, and late—as in the case of Cucumbers, is much needed; inasmuch as any one anxious for an early crop of Melons has no trustworthy data to guide him. Some recommend Little Heath, some Scarlet Gem, and others Merton Hall or Queen Emma, as the best for an early crop; Hero of Bath is also well spoken of as an early kind, and I observe that Mr. Penny, of Sandringham, describes The Prince's Favourite as a fortnight earlier than Hero of Bath, and asserts that it is in all respects a first-rate Melon. The gain of a fortnight as respects ripening is a great advantage in a Melon; and I hope that some of the readers of THE GARDEN may be induced to give their experience in relation to the best varieties for early crops. Many years ago the Early Cantaloup was extensively grown as an early Melon, and Bromham Hall, Cuthill's Scarlet Flesh, Golden Perfection, and Pine-apple Gem are also good early kinds. Can any one name a variety better and earlier than those just adverted to, that is, a Melon of good quality that will be ripe in less time from the date at which it is planted under ordinary treatment in houses, pits, or frames?—D. T. FISH.

Soot and Lime v. Birds.—Those who, like myself, are troubled with birds picking the buds off their Gooseberry and Currant trees may derive some benefit from the following remarks:—In 1875 I had some of the trees here almost completely stripped of their buds; consequently very little fruit was the result. I had pruned early so as to forward the work as much as possible. In 1876 I pruned as usual, viz., about the beginning of the year; after all were pruned, I had both Gooseberry and Currant bushes well dusted with lime and soot mixed when the bushes were wet, in order that the mixture might adhere to the trees, and the result has been most satisfactory, not a bud having been taken after the bushes were dressed. This season I pruned about the same time as last year, and had them dusted in the same way, and the result has been equally satisfactory. I have, however, had to repeat the operation lately, as the heavy rains had nearly washed the first dressing off. I read (see p. 104) that Mr. Groom prefers pruning in the spring when the buds are just bursting into leaf; that may be all very well, but few can spare the time to prune at that particular period of the year. As for shot and powder, which he recommends, I have always found them to be more destructive than even the birds, especially if shot into the bushes or trees, as the shots injure the wood and cause canker.—WILLIAM WYNN, Stamford.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Grafting Figs.—Figs are constantly grafted or rather budded in this country, the time being March, varying slightly according to the situation; the usual way is budding as practised for Roses, Lemons on bitter Orange stocks, &c. Several large trees, which were budded two years ago, gave me a fair crop last season. Another mode is "flute" grafting, i.e., taking a ring of bark with the bud and fitting it rapidly and accurately on the prepared stock. Probably Mr. Lee attempted grafting when the season was too far advanced.—SOUTH ITALY.

Bleeding in Vines.—Can any one tell me how to stop Vines from bleeding? I pruned mine in December, and gave them the usual dressing on January 28, nevertheless this week they have started bleeding at almost every spur. It is the late Vinery in which the occurrence has taken place, although I have given air day and night; the border, too, has been covered with leaves and rough manure since the 1st of November.—C. Eaton, Derby. [Drying the ends with a hot iron, and coating them over with patent knotting, used by painters, will often stop Vines from bleeding, but, with the mild weather and the growing season close at hand, the best remedy is to close the Vinery and start them into growth.—JAMES SMITH, Waterdale.]

Vines for a New Vinery.—I am building a Vinery 36 ft. long and 12 ft. wide; I can only give an outside border 1 ft. wide; it will, therefore, be more convenient to place the Vines inside with openings in the foundation wall to let the roots run through. Will the Vines do as well planted in this manner as if planted outside? I shall not force very much, but use warmth when requisite. How many Vines ought I to plant in this house, and what kinds? Will some of your correspondents help me in this matter?—OLD SUBSCRIBER.

PLATE LXII.

EXOCHORDA GRANDIFLORA.

Drawn by Mrs. DUFFIELD.

ALTHOUGH this handsome hardy deciduous shrub has been in cultivation in this country for nearly a quarter of a century, it has not received the attention it deserves, and is still very rarely seen in our gardens. It is one of the numerous ornamental shrubs introduced from China by Mr. Fortune, who first found it in North China in 1845, and in the following year he collected fruiting specimens of it in the Che-Kiang hills. Mr. Fortune took it to be a species of *Amelanchier*, and sent seeds of it to Messrs. Standish and Noble, of the Bagshot Nurseries, under the name of *A. racemosa*. It certainly bears a general resemblance to the genus in question, especially in its flowers, but it differs widely in the structure of the latter. The exact date of its introduction I have not been able to ascertain, but it appears to have been first exhibited in 1854, and the same year it was figured in the "Botanical Magazine," under the name of *Spiraea grandiflora*. But the general aspect of this shrub is so different from most of the *Spiraeas*, and the flowers so much larger, that, independently of less obvious characters, it possesses some claims to generic rank. It was Dr. Lindley ("Gardeners' Chronicle," 1858, p. 925) who gave it the name which it now bears; and writing at that date, he speaks highly of its merits. One character, which specially recommends this shrub, is its early and long-flowering season, from early in April onwards. It is a very distinct shrub, and perfectly hardy in the neighbourhood of London, flowering profusely on warm soils with gravelly bottoms. Like some of the shrubby *Spiraeas* it requires a little pruning and trimming to keep it neat. It is of bushy habit, and grows to a height of 8 ft. or 9 ft., and probably higher under favourable conditions. There is a plant of it in the collection of shrubby *Rosaceae* in the pleasure grounds at Kew, the main branches of which are from 2 in. to 3 in. in diameter at the base. Its botanical affinities are with the genera *Stephanandra*, *Kerria*, and *Rhodotypus*, all natives of the same region. W. B. H.

Herbaceous Plants Suitable for Beds.—Some time ago a question was asked in THE GARDEN whether there were herbaceous plants suitable for bedding during the summer months, to which I do not think very satisfactory answers were given. *Delphinium formosum*, lovely for a time, is by no means a continuous bloomer, even when the seed-vessels are gathered, nor are there any *Delphiniums* as yet raised that bloom continuously. In the garden of Mr. Henry Sherbrooks, Oxtou, Notts, there is a magnificent bed of blue never out of bloom: it is *Campanula carpatica*. The white variety would no doubt bed equally well. *Campanula trachelium* might be still more successful, but I have never seen a fine variety of *trachelium*. There is a lovely white *Delphinium*, though not so tall as *formosum*, known as *Delphinium chinense album*.—FRANK MILES, Bingham.

Clematis Fence.—After all, none of the hybrid *Clematises* equal *C. Jackmanni* for continuity and density of bloom. A lovely one is the six-petaled, rich violet, free-blooming variety, known as Thomas Moore. Mr. Anderson Henry's hybrids make growth too late in the year, and get caught by the winter. I have only had two blossoms of *L. Henryi* in two seasons, but those blossoms were enormous. All the hybrids from *C. lanuginosa* get killed off or disappear somehow in a season or two, but *C. Jackmanni* is always to the fore. At the back of my long border there is a fence of plaited laths, and the whole way I have plants of *C. Jackmanni*, so the fence will be a purple mass this summer. When the plants have done blooming late in the autumn, I carefully disentangle the growths, and lay them down in a shallow trench along the base of the fence, putting 3 in. or 4 in. of rich soil over them, and just leaving out of the ground the end shoot, which is just beginning to swell. All the buds will grow, and the shoots spear through the soil. When they have ceased flowering in autumn they begin to make root-growth at the base of each shoot, so by spring one can detach them or leave them to strengthen the fence. One cannot have too many plants of *Clematis Jackmanni*; a good thing always keeps its proper value.—F. M.

Bouvardias for Winter.—We grow *Bouvardias* here in a succession Pine stove in which they are subjected to rather a brisk heat, and thus treated they furnish us with plenty of cut flowers for some three months when they are most wanted. Four of the best are *B. jasminiflora*, *Bridal Wreath*, *Humboldtii*, and *Davisonii*.—DAVID BURKE, Boughley.

THE LIBRARY.

DARWIN ON ORCHID FERTILIZATION.*

THE first edition of this remarkable book, which was published early in 1862, gave an impetus to the study of plant-life

in its relation to insects, and since its appearance the subject has been pursued with advantage by Lubbock, Bennett, Müller, and others. Although not so valuable to practical horticulturists as the recently published "Cross and Self-Fertilization of Plants," by the same author, this book is nevertheless most instructive, and a work which may be read with advantage by all who are interested in the higher branches of plant-life. The following extract, relating to the production and vitality of Orchid seeds,

will, we feel sure, be read by many with much interest:—

The final end of the whole flower, with all its parts, is the production of seeds, and these are produced by Orchids in vast profusion. Not that such profusion is anything to boast of; for the production

of an almost infinite number of seeds or eggs is undoubtedly a sign of lowness of organization. That a plant, not being an annual, should escape extinction, chiefly by the production of a vast number of seeds or seedlings, shows a poverty of contrivance, or a want of some fitting protection against other dangers. I was curious to estimate the number of seeds produced by some few Orchids; so I took a ripe capsule of *Cephalanthera grandiflora* and arranged the seeds on a long ruled line as equably as I could in a narrow hillock; and then counted the seeds in an accurately measured length of one-tenth of an inch. In this way the contents of the capsule were estimated at 6020 seeds, and very few of these were bad; the four capsules borne by the same plant would have therefore contained 24,080 seeds. Estimating in the same manner the smaller seeds of *Orchis maculata*, I found

the number nearly the same, viz., 6200; and, as I have often seen above thirty capsules on the same plant, the total amount would be 186,300. As this Orchid is perennial, and cannot in most places be increasing in number, one seed alone of this large number yields a mature plant once in every few years. To give an idea to what the above figures really mean, I will briefly show the possible rate of increase of *O. maculata*: an acre of land would hold 171,240 plants, each having a space of 6 in. square, and this would be just sufficient for their growth; so that, making the fair allowance of 400 bad seeds in each capsule, an acre would be thickly clothed by the progeny of a single plant. At the same rate of increase, the grandchildren would cover a space slightly exceeding the island of Anglesea; and the great grandchildren of a single plant would nearly (in the ratio of 47 to 50) clothe with one uniform green carpet the entire surface of the land throughout the globe. But the number of seeds produced by one of our common British Orchids is as nothing compared to that of some of the exotic kinds. Mr. Scott found that the capsule of an *Acropeta* contained 371,250 seeds; and judging from the number of flowers, a single plant would sometimes yield about 71,000,000 seeds. Fritz Müller found 1,756,410 seeds in a single capsule of a *Maxillaria*; and the same plant sometimes bore half-a-dozen such capsules. I may add that by counting the packets of pollen (one of which was broken up under the microscope) I estimated that the number of pollen-grains, each of which emits its tube, in a single anther of *Orchis mascula* was 122,400. A micist estimated the number in *O. morio* at 120,300. As these two species apparently do not produce more seed than the allied *O. maculata*, a capsule of which contained 6200 seeds, we see that there are about twenty pollen-

grains for each ovule. According to this standard, the number of pollen-grains in the anther of a single flower of the *Maxillaria* which yielded 1,756,410 seeds must be prodigious. What checks the unlimited multiplication of the Orchideæ throughout the world is not known. The minute seeds within their light coats are well fitted for wide dissemination; and I have several times

21. *L. pardalinum* (California): from a good-sized cultivated specimen; the small figures show entire and jointed scales and sections of the variably-shaped scales, &c.; colour, white or yellowish, rarely suffused with pink. [See p. 156.]

21. *L. superbum* (America—Eastern United States): from a cultivated specimen 1. Bulb, natural size. 2. Rhizome-bearing bulbs, about one-half natural size. 3 and 4. Variable entire scales. 5. Ditto jointed scales, section, &c. Colour, white, delicately suffused with salmon-pink. [See p. 156.]

* "The Various Contrivances by which Orchids are Fertilized by Insects." By Chas. Darwin, M.A., F.R.S. Second Edition. London: John Murray.

observed seedlings springing up in my orchard and in a newly-planted wood, which must have come from a considerable distance. This was especially the case with *Epipactis latifolia*; and an instance has been recorded by a good observer of seedlings of this plant appearing at the distance of between eight and ten miles from any place where it grew. Notwithstanding the astonishing number of seeds produced by Orchids, it is notorious that they are sparingly distributed; for instance, Kent appears to be the most favourable county in England for the Order, and within a mile of my house, nine genera, including thirteen species, grow; but of these one alone, *Orchis morio*, is sufficiently abundant to make a conspicuous feature in the vegetation; as is *O. maculata* in a lesser degree in open woodlands. Most of the other species, though not deserving to be called rare, are sparingly distributed; yet, if their seeds or seedlings were not largely destroyed, any one of them would immediately cover the whole land. In the tropics the species are very much more numerous; thus Fritz Müller found in South Brazil more than thirteen kinds, belonging to several genera, growing on a single *Cedrela* tree. Mr. Fitzgerald has collected within the radius of one mile of Sydney in Australia no less than sixty-two species, of which fifty-seven were terrestrial. Nevertheless the number of individuals of the same species is, I believe, in no country nearly so great as that of very many other plants. Lindley formerly estimated that there were in the world about 6000 species of Orchideæ, included in 433 genera.

The number of the individuals which come to maturity does not seem to be at all closely determined by the number of seeds which each species produces; and this holds good when closely related forms are compared. Thus *Ophrys apifera* fertilizes itself, and every flower produces a capsule; but the individuals of this species are not so numerous in some parts of England as those of *O. muscifera*, which cannot fertilize itself, and is imperfectly fertilized by insects, so that a large proportion of the flowers drop off unimpregnated. *Ophrys aranifera* is found in large numbers in Liguria, yet *Delpino* estimates that not more than one out of 3000 flowers produces a capsule. Mr. Cheeseman says that with the New Zealand *Pterostylis trullifolia*, much less than a quarter of the flowers, which are beautifully adapted for cross-fertilization, yield capsules; whereas with the allied *Acianthus Sinclairi*, the flowers of which equally require insect aid for their fertilization, seventy-one capsules were produced by eighty-seven flowers—so that this plant must produce an extraordinary number of seeds; nevertheless in many districts it is not at all more abundant than the *Pterostylis*. Mr. Fitzgerald, who in Australia has particularly attended to this subject, remarks that every flower of *Thelymitra carnea* fertilizes itself and produces a capsule; yet it is not nearly so common as *Acianthus fornicatus*, the majority of the flowers of which are unproductive. *Phajus grandifolius* and *Calanthe veratrifolia* in similar situations. Every flower of the *Phajus* produces seeds; only occasionally, one of the *Calanthe*, yet *Phajus* is rare, and *Calanthe* common.

The frequency with which throughout the world members of various Orchideous tribes fail to have their flowers fertilized, though these are excellently constructed for cross-fertilization, is a remarkable fact. Fritz Müller informs me that this holds good in the luxuriant forests of South Brazil with most of the *Epidendrea*, and with the genus *Vanilla*. For instance, he visited a site where *Vanilla* creeps over almost every tree, and although the plants had been covered with flowers, yet only two seed-capsules were produced. So again with an *Epidendrum*, 233 flowers had fallen off unimpregnated, and only one capsule had been formed; of the still remaining 136 flowers, only four had their pollinia removed. In New South Wales Mr. Fitzgerald does not believe that more than one flower out of a thousand of *Dendrobium speciosum* sets a capsule; and some other species there are very sterile. In New Zealand over 200 flowers of *Coryanthes triloba* yielded only five capsules; and at the Cape of Good Hope only the same number were produced by 78 flowers of *Disa grandiflora*. Nearly the same result has been observed with some of the species of *Ophrys* in Europe. The sterility in these cases is very difficult to explain. It manifestly depends on the flowers being constructed with such elaborate care for cross-fertilization, that they cannot yield seeds without the aid of insects. From the evidence which I have given elsewhere we may conclude that it would be far more profitable to most plants to yield a few cross-fertilized seeds, at the expense of many flowers dropping off unimpregnated, rather than produced many self-fertilized seeds. Profuse expenditure is nothing unusual under Nature, as we see with the pollen of wind-fertilized plants, and in the multitude of seeds and seedlings produced by most plants in comparison with the few that reach maturity. In other cases the paucity of the flowers that are impregnated may be due to the proper insects having become rare under the incessant changes to which the world is subject; or to other plants which are more highly attractive to the proper insects having increased in number. We know that certain Orchids require

certain insects for their fertilization, as in the cases before given of *Vanilla* and *Sarcochilus*. In Madagascar *Angraecum sesquipedale* must depend on some gigantic moth. In Europe *Cypripedium calceolus* appears to be fertilized only by small bees of the genus *Andrena*, and *Epipactis latifolia* only by wasps. In those cases in which only a few flowers are impregnated owing to the proper insects visiting only a few, this may be a great injury to the plant; and many hundred species throughout the world have been thus exterminated; those which survive having been favoured in some other way. On the other hand, the few seeds which are produced in these cases will be the product of cross-fertilization, and this, as we now positively know, is an immense advantage to most plants.

A NEW TEXT-BOOK OF BOTANY.*

It might be supposed that students were already sufficiently supplied with "text books" of botany, but the appearance of the present volume seems to show that this opinion is not shared by all authors and publishers. The fact that "the original of the work is the recognised Text-book of Botany in use in the technical schools of Germany," and the translator's belief that no work of the same scope is to be found in the English language, have combined to produce the publication of this latest addition to our list of text-books; and, if it be admitted that any addition was required, we think that the present is the most useful which could have been made. It is handy, very compendious and comprehensive, and illustrated by between five and six hundred woodcuts, some of which are as "old familiar faces" to us, so often have we encountered them in botanical works; moreover, and this is noteworthy, there is a very good index; and the only fault we have to find with the get-up of the book is that the margins are somewhat too narrow. With regard to the contents, it appears to us that the editing has been very judiciously executed, the additional notes of the editor being to the point, and giving in some cases important information not to be found in the original work. The section in the classification of Phanerogams has been entirely rewritten; and there is a brief but very useful epitome of Grisebach's conclusions upon geographical distribution, which is the more acceptable, as there is at present no English translation of that author's important work, and is accompanied by a coloured map. It would be beyond our purpose to enter into anything like a detailed notice of this Text-book; but we can strongly recommend it to readers as being really what it professes to be—the most compendious work embracing the whole range of Elementary Botany which has yet appeared in the English language.—J. B.

The Cactus.†—This little volume consists of a series of essays by Mr. Croucher and others, called by Mr. Alnutt from various sources and arranged in book form for the use of amateurs who have a taste for Succulent Plants, the whole being illustrated by a tinted plate as a frontispiece. Many of the woodcut engravings are, however, old and worn, and might have been omitted with advantage. To amateurs and window gardeners who wish to grow a few Succulent Plants, and who are desirous of gaining some general knowledge of their history, this little work will be useful; but a really comprehensive work on Succulent Plants, corresponding to the French works by Labouret and Lemaire, still remains to be written.

Glazing Without Laps.—In spite of all the novelties that exist in the way of glazing, the old and really inconvenient plan of having laps and using putty still remains the common mode of glazing horticultural structures. All lapped glass should have sufficient space left under the lap to admit of some thin substance being run up between to clear out the dirt that will assuredly accumulate there. Would it not be possible to have panes of glass made exactly to size, with perfectly even ends and slightly hollowed in the centre like glass pantiles? Then, if a very narrow groove were ploughed out of the side of each bar, these glass tiles might be slid up to the top and so filled up until the bottom of each pair of bars was reached. In this case all the rainfall would naturally keep to the centre of the glass, but in the present mode of glazing the water prefers the putty sides, and, working beneath these, causes a drip. The system of fixing glass with putty ought long since to have been abolished.—D.

LILY BULBS—III.

DUCHARTRE has pointed out the great difference observable in the periods occupied by the germination of different kinds of Lily seeds, inasmuch as while those of *L. tenuifolium* germinate in a few weeks, and form little bulbs bearing several leaves within the first year, the seeds of *L. auratum* and of other kinds lie in the ground at least a year before they show any signs of leaf growth. A proportionate difference is observable in the time which elapses between the germination of the seed, and the blooming period of the resulting seedling plants; and seeing that these differences exist, it is not surprising to find that there is an individuality about some Lily bulbs, notably in the case of *L. polyphyllum*, *L. auratum*, and *L. tenuifolium*, by which they may be identified the first or second year from seed, or at least in most cases long before they have attained their full dimensions and flowering stage. Neither botanists nor cultivators give plants sufficient credit for their indescribable characters, which are often, as in the case of Lilies, observable almost from the appearance of the first young seed growth. These characters in the case of many nearly related varieties of other cultivated plants, as in Heaths, Rhododendrons, and Grape Vines, are amply sufficient to enable cultivators to distinguish plants of any variety with unerring accuracy, notwithstanding the fact that any attempt to describe their minor differences in words would be useless for purposes of discrimination and selection. Hence it is no uncommon occurrence to find cultivators who can unmistakably recognize almost all varieties of Heaths or Grape Vines by their woody growth or foliage alone. And if ever we are to know anything more of plant life in its higher bearings, we must put in practice De Candolle's advice to Mrs. Somerville, and live with, and observe the cycle of plant growth in all its stages from the germination of the seed to the full development of the fruits. Although our sketches and descriptions herewith concluded show a remarkable diversity in the form and growth of Lily bulbs, it must not be supposed that the underground stem development of Lilies, Crocuses, Fritillarias, and other allied bulbous plants is alone worthy of consideration, since the true root growth of many trees, shrubs, and herbaceous plants is in many cases even more distinct and constant in character than are their aboveground stems, leaves, flowers, or fruits.

Sub-genus 4.—*Martagon*.

Perianth always drooping, broadly bell-shaped, its divisions lanceolate, broadest about the middle, not distinctly clawed, distinctly reflexed when fully expanded; stamens diverging much on all sides from the centre of the flower; and style declinate.

18. *L. Martagon*.—Another extremely variable plant, bearing white, red, purple, nearly black, and yellowish flowers on conical spikes, the bulbs of all the forms being of a bright yellow colour. Mr. Baker describes the bulb of this species as being "ovoid, 1½ in. to 2 in. long, yellowish perianth, with very numerous, narrow scales." Our figure of *L. Wallichianum* shows the general contour and size of the bulbs of *L. Martagon*, except that these last are more elongated, with narrow, entire-margined, clear yellow scales.

[*L. Martagon*, Linn.—Central and Southern Europe and Siberia. Var. 1. *Martagon prorep.*—Figured in *Bot. Mag.*, t. 893 and 1634; *Red. Lil.*, t. 146; *Jacq. Austr.*, t. 351; *Eagl. Bot.*, t. 279, 3rd edit., t. 1518; *Reich. Ic. Germ.*, t. 451. Var. 2. *Hirsutum*, Miller. *Syn.*, *L. Milleri*, Schultes. Var. 3. *Glabrum*, Sprengel. Var. 4. *Cattaneo*.—Dalmatia; figured in *Visiani Fl. Dalm. Suppl.*, t. 3. *Syn.*, *L. Martagon var. dalmaticum*, Mily.]

19. *L. maculatum*.—There has been some little misunderstanding about this plant; there can be but little doubt, however, that the *L. maculatum* of the *Bot. Mag.*, t. 6126, is really *L. Hansoni*, the *L. maculatum* of Thunberg being merely a form of *L. elegans*. The bulb of *L. avenaceum* was comparatively unknown until 1877, when Mr. Barr received a small consignment by way of America, from which, however, it must not be inferred that it is otherwise than a Japanese, Kamchatkian, Manchurian, and Kurilean plant. The bulbs, are pale yellow or straw-coloured, globose, varying in size from that of a Hazel Nut to that of a medium-sized Walnut, the narrow scales being lanceolate, slightly triquetrous, sharply pointed, many of them being distinctly articulated about the middle, and readily broken if roughly handled. The name *avenaceum* or Oat-scaled, is

peculiarly applicable to the bulbs of the true plant, since the upper half of the scales when broken off closely resemble Oats in form and colour. *L. Hansoni* and *L. avenaceum* differ mainly in the bulb, the first named, however, being the most ornamental plant; it is also the *L. maculatum* of the "*Botanical Magazine*," t. 6126. *L. Hansoni* is figured in the "*Botanical Magazine*" as *L. maculatum*, and in the "*Flerist*" as *L. avenaceum*, but it is a distinct Lily, and was shown at a meeting of the Royal Horticultural Society in 1874 by Mr. G. F. Wilson, of Weybridge, who kindly supplied the bulb from which our drawing was made. Mr. Baker long regarded this plant as synonymous with *L. maculatum*, and the same opinion was expressed at

19. *L. avenaceum* (Japan); from an imported bulb; natural size.

the meeting at which the plant was shown by Dr. Hooker. Herr Leichtlin, however, who is an authority on all that concerns the genus to which this plant belongs, considers the name of *L. maculatum* as being synonymous with *L. medeoloides*, a figure of Thunberg's published in the "*Memoirs of the Academy of St. Petersburg*" being the authority for this opinion; this figure is looked on by Mr. Baker as in some degree supporting Herr Leichtlin's opinion, without, however, fully proving it. In his "*Notes on Lilies*," published in the *Linnean Society's "Journal*," Mr. Baker has adopted for the present plant the name *L. Hansoni*. Thunberg's description of a bell-shaped perianth by no means agrees with the present species. The plant is

19.* *L. Hansoni* (Japan); from a well-grown cultivated bulb; half natural size. colour, yellowish white, suffused with purple.—1 and 2. Scales, in different positions. 3. Section of scale, natural size.

about 2 ft. high, with distant whorls of leaves 1 in. wide on the lower part of the stem, near the top of which the leaves became alternate, a rather loose umbel of five or six flowers crowning the whole. The flowers are very distinct in form, having scarcely any tube, so that the blossoms are fully 3 in. across; and they are of a deep tawny orange colour, with a thickish cluster of black spots towards the base. The flowers are somewhat nodding, but the style makes an angle with the top of the ovary so as to assume an upward direction. The ovary itself is very deeply six-winged. This Lily flowers in June, and is perfectly hardy.

[*L. maculatum*, Thunberg.—Kamchatka, Manchuria, Japan, Russian America; figured in *Mem. Acad. Petersb.*, 3, t. 5. *Syn.*, *L. avenaceum*, Fisch. Maxim.; figured in *Regel Gartenfl.*, t. 485. Mr.

Baker informs me he has recently seen Thunberg's type specimen of *L. maculatum*, and as it is in reality nothing more than a form of *L. elegans*, the name *L. maculatum* must be discontinued.]

20. *L. canadense*.—A variable plant long known in cultivation, having been figured and described by Parkinson as long ago as 1629. Mr. Baker describes the bulbs as "emitting runners 5 in. to 6 in. long; scales thick, obtuse, scarcely $\frac{1}{2}$ in. long." The bulbs are borne an inch or two apart on a stout rhizome, and are about $1\frac{1}{2}$ in. in diameter. The yellow scales are very variable in shape and size, some being short and rounded, others lengthened and lance-shaped, some few of them being jointed. *L. canadense*

19. *L. canadense* (Canada, United States, California): imported bulb; natural size; small figures show rhizomatous habit of growth and jointed or entire scaled bulbs; colour, white, yellow if exposed, rarely suffused with pink.

parviflorum has its bulbs clustered more closely together, something in the way of those of *L. superbum*. The pretty little *L. canadense parvum* has a very distinct bulb, formed of a rhizome 2 in. or 3 in. in length, covered with clustered, white, jointed scales, as shown in our illustration. I saw a whole importation of such bulbs at Mr. Bull's, and although they were very variable in size, I noted none in which there was a tendency to have the scales arranged bulb-fashion around a vertical root-stock; indeed, the bulbs are elongated just as in *L. Washingtonianum*, only narrow, fleshy, ivory-white, jointed scales are here substituted for thin, lance-shaped ones. The bulb growth of *L.*

20. *L. parvum* (= *L. canadense parvum*): imported bulb; natural size; colour, ivory-white, yellowish if exposed.

canadense having been fully described in our last week's paper on Lily bulbs, there is no necessity for further allusion to the matter here.

[*L. CANADENSE*, Linnaeus.—Canada, Eastern United States, and California. Var. 1. *Canadense* proper.—Canada and Eastern United States; figured in Bot. Mag., t. 800 and 858; Bury Hexand., t. 12; "Flore des Serres," t. 1174. Var. 2. *Parvum*.—California: figured in Kellogg, Proc. Calif. Acad. ii., p. 179, t. 52; Regel Gartenfl., t. 725. Var. 3. *Puberulum*, Leichtlin, not Torrey. — California. Var. 4. *Walkerii*, Wood.—California.]

21. *L. superbum*.—A stately bog Lily, likely to become a permanent inmate of our garden. Mr. Baker describes the bulb as being "largo, caespitose, globose, perennial; scales numerous, acute, closely

imbricated tinged with red." *L. carolinianum* has similar bulbs. *L. pardalinum* has bulbs quite distinct, however, being rhizomatous, zigzagged, forming little mat-like masses of roundish oblate bulbs and thick, scaly rhizomes. The bulb scales of this Lily are in some specimens almost all jointed near the base, and can easily be rubbed off.

[*L. SUPERBUM*, Lionæus.—Var. 1. *Superbum* proper.—Eastern United States; figured in Bot. Mag., t. 936; Red. Lil., t. 103; Bury Hexand., t. 36; "Flore des Serres," t. 1014.5. Var. 2. *Carolinianum*, A. Gray.—Eastern United States; figured in Mich.; Bot. Mag., t. 2280; Bot. Reg., t. 580 (not Catesby). Syn., *L. Michauxii*, Poir.; *L. Michauxianum*, Schultes fil.; *L. autumnale*, Lodd. Bot. Cab., t. 335. Var. 3. *Pardalinum*.—California: figured in Kellogg, Proc. Calif. Acad. ii. p. 12. Var. 4. *Bourgei*, Baker.—British Columbia.]

22. *L. columbianum*.—Mr. Baker describes the bulb as "ovoid, perennial, small, white, acute, with lance-shaped scales," and also adds that the plant "scarcely differs from *L. canadense* var. *parviflorum*, except in the bulb not being rhizomatous." I have seen this pretty little variety in flower at Mr. Barr's bulb ground, and he and I agreed in considering it a dwarf, small-flowered variety of *L. Humboldtii* analogous to, and, so far

22. *L. columbianum* (America): cultivated bulb, natural size; colour, yellowish white.

as above-ground development goes, not unlike the small-flowered forms of *L. canadense*, *L. canadense parviflorum*, and *L. parvum*, but, as Mr. Baker so well points out, easily recognizable by examining the bulb-growth.

[*L. COLUMBIANUM*, Hort. Leichtlin.—Oregon and British Columbia. Syn., *L. Sayii*, Nuttall mss.; *L. canadense*, var. *parviflorum*, Hook.; *L. canadense*, var. *minus*, Wood.—This plant has the bulbs of *L. Humboldtii*, except in their being smaller, with a tendency to assume a sub-rhizomatous habit in some examples.]

23. *L. Humboldtii*—A very stately Lily, attaining a height of 8 ft. to 10 ft. even when grown in pots. Mr. Baker describes the bulbs as being "large, 2 in. to 4 in. in diameter, oblique, perennial, not rhizomatous; scales ovate, lanceolate, acute, 2 in. to 3 in. long." I saw several hundreds of fine bulbs of the plant at Mr. Bull's, all singularly alike in form, being ovoid, globose, the pointed scales all curving and facing one way, while the thick roots pointed in the opposite direction. The typical *L. Humboldtii* generally has white, scaled bulbs, but specimens sent by the New Plant and Bulb Company from Colchester were yellowish, tinged with pink or purple. Mr. Bull's examples of *L. Bloomerianum ocellatum* were also small, plump, and purplish, profusely dotted with purple as in *L. Browni*. Mr. Barr tells me, however, that in Rozel's importation of *L. Bloomerianum ocellatum* there were about half the bulbs with white scales and half with purple ones, from which it was at the time inferred that there were two varieties, but on flowering, both sets of bulbs gave flowers precisely similar in colour. If our figure of the

bulb of *L. columbianum* were enlarged four or five times, it would stand very well for that of *L. Humboldtii*. Mr. Bull tells me that the bulbs of *L. Bloomerianum* proper are the largest of this type, being 6 in. or more long and 4 in. or 5 in. in diameter; whereas, the bulbs of the plant now known in gardens under the name of *L. Bloomerianum ocellatum* are rarely larger than those of *L. columbianum*, having, however, plumper, blunter scales.

[*L. HUMBOLDTII*, Roez and Leichtlin in *Daehartre Obs.*, p. 105.—California; figured in "*Regel Gartenfl.*" t. 72k; *Fl. des Serres*, t. 1973-f. Syn., *L. canadense*, var. *puberulum*, Torrey Bot. Whipple, p. 90; *L. Bloomerianum*, Kellogg, *Proc. Calif. Acad.*, iv., p. 60; *L. californicum*, Hort. Angl.]

24. *L. Roezli*.—Mr. Baker describes the bulb of this plant as being perennial and rhizomatous, "and it is further said to be readily distinguished in habit from allied forms by having narrow acute leaves, and perianth segments."

[*L. ROEZLI*, *Regel Gartenfl.*, t. 667.—California, Utah. Syn., *L. canadense*, var. *Hartwegi*, Baker in *Gard. Chron.*, 1871, p. 321.]

25. *L. monadelphum*.—This plant has a large, ovoid, pointed, perennial bulb, the scales of which are narrow, lance-shaped, closely imbricate, and pointed, most of the inner scales being white, but the outer ones yellow, often tinged with pink or purple where exposed. Our figure of the bulb of *L. carniolicum* var. *albanicum*, very nearly resembles that of *L. monadelphum* Szovitsianum, except that the yellow scales of the last-named are rather broader; the general contour and appearance, however, are identical.

[*L. MONADELPHUM*.—Var. 1. *Monadelphum* proper.—Caucasus and Asia Minor; M. Bieb. *Cent. Ross.*, t. 4; *Bot. Mag.*, t. 1405; *Reich. Exot.*, t. 89; *Regel Gartenfl.*, t. 733. Syn., *L. Loddigesianum*, Schultes fil.; *Lemaire Jard. Fleurs.*, t. 201; *Paxt. Flow. Gard.*, t. 58; "*Flore des Serres*," t. 507-9. Var. 2. *Szovitsianum*.—Asia Minor; figured in *Fisch. & Lall. Regel Gartenfl.*, t. 536; "*Flore des Serres*," t. 507-9. Syn., *L. colchicum*, Stevcn.]

26. *L. carniolicum albanicum* (Europe); natural size; cultivated bulb.

26. *L. carniolicum*.—The bulb of this plant is the size of a duck's egg, globose, or slightly pointed, the scales being broad, lance-shaped, and $\frac{1}{2}$ in. to $\frac{3}{4}$ in. in breadth. Sometimes, however, we find enormous bulbs of this species 5 in. to 7 in. in diameter, formed of several centres, each of which throw up a stem. The colour of the scales is generally white or yellowish, the more exposed slightly tinged with purple. The bulbs of the albanicum variety are more ovoid in shape, tapering to a point above, and the scales are twice as numerous and as long (say about $2\frac{1}{2}$ in. to $3\frac{1}{2}$ in.), but only half as broad, many of the scales being only $\frac{1}{4}$ in. to $\frac{1}{2}$ in. in breadth, and of a bright yellow colour, as in *L. Martagon*.

[*L. CARNIOLICUM*, Bernhold.—Lombardy, Austria, and Turkey. Var. 1. *Carniolicum* proper.—Same distribution; figured in

Reich. Ic. Germ., t. 990. Syn., *L. chalcidonicum*, Linn. in part; *Jacq. Fl. Austr. Supp.*, t. 20. Var. 2. *Albanicum*.—Albania and Transylvania.]

27. *L. ponticum*, L. Koch.—Asia Minor; not known in cultivation.

28. *L. polyphyllum*.—This is by no means a well-known Lily, although I learn from Mr. M'Nab that it has been growing in the open ground in the Botanic Garden at Edinburgh for several years, and has flowered pretty regularly. Seedlings

23. *L. polyphyllum* (Indian); seedling bulbs, about four years old colour, white.

from the first flowering specimen have also since bloomed, no difference having been observed in their growth or flower, although other species were flowering near the parent plant at the time it was in blossom. It has been grown in other gardens, and was described by Royle as *Fritillaria polyphylla*, under which name it was received at Edinburgh; and this may have prevented many Lily growers from obtaining the plant, thinking it belonged to a not over beautiful and allied family, but that it is essentially a Lily in bulb and flower there can be no doubt. My sketch of the singular

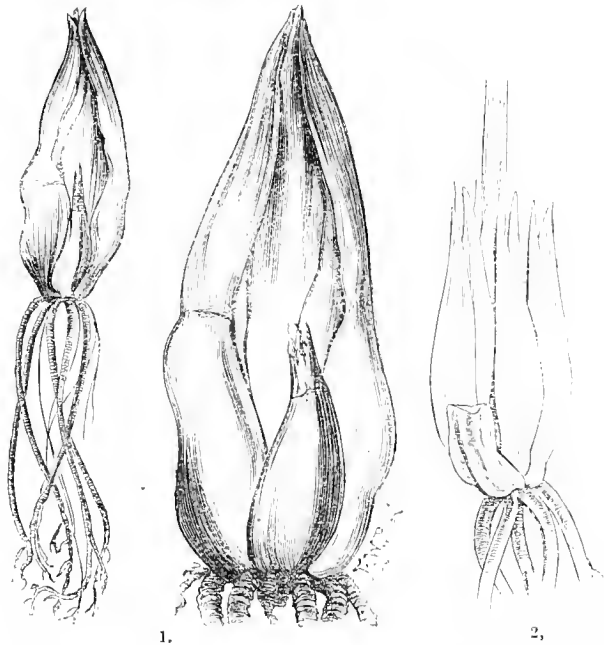

25. *L. (Fritillaria) polyphyllum* (India); full-sized cultivated bulb from Colchester.

narrow seedling bulbs was made at Mr. Barr's ground in January of the present year. I sent a copy of it to Mr. M'Nab, who has succeeded so well in the open-air culture and seed propagation of the plant; he in reply remarks, "The bulbs are certainly very distinct, quite of the shape you figure, but somewhat larger." Mr. H. J. Elwes, who also saw a copy of the sketch, tells me that he has succeeded in raising seedlings from the Edinburgh plants, the bulbs of which now much resemble the drawing here given; and the same gentleman adds, "It is one of the most unmistakable bulbs; I know no other like it, except perhaps that of *L. oxypetalum*, which I only know from the figure in the '*Botanical Magazine*' fifteen years or more ago. The bulb of *L. polyphyllum* attains 3 in. or 4 in. in length when fully grown, and it may be distinguished at the age of one year

from seed with certainty." *L. polyphyllum* is said by one of Mr. Barr's correspondents at Mussoorie to belong to the Turk's-cap group; grows in good, tolerably moist vegetable mould on a slope in thick shrubbery, and flowers there in June at an elevation of 6500 ft. Quite recently bulbs of this species have been imported and sold at Stevens', so that it will doubtless soon become better known in our gardens if not coddled to death, as happens to so many plants and bulbs from elevated and consequently comparatively cool habitats within the tropics. Mr. Horseman tells me that the imported bulbs of this plant acquire a large size in the open air at Colechester. Our illustrations represent seedling bulbs of this plant when about four years old, a well-developed flowering bulb as grown at Edinburgh, and also another grown at Colechester.

[*L. POLYPHYLLUM*, Royle.—Western Himalayas, temperate region. Syn., *L. punctatum*, Jacquemont, Duchartre Obs., p. 77.]

28. (Fig. 1.) *L. (Fritillaria) polyphyllum* (India); cultivated bulb from Edinburgh Botanic Garden. (Fig. 2.) *L. (Fritillaria) oxypetalum* (Indian); flowering bulb from Bot. Mag., vol. 73, t. 4731; colour, white.

29. *L. chalcedonicum*.—A well-known and beautiful plant, the most vivid in its scarlet colour of all the Lilies. There are now several varieties, the plant having been grown from seeds by some of the Dutch bulb-growers. Considering the size of the plant and comparatively small area of leafage, the bulb is enormous, being as large or larger than a duck's egg, ovoid in form and pointed, the scales being lance-shaped and closely imbricated, some of the outer ones being slightly constricted about the centre. Many of the bulbs are 3 in. to 4 in. in length, and fully 3 in. in diameter, the colour of the inner scales being whitish, and the outer ones yellow, some suffused with purplish-pink or orange.

[*L. CHALCEDONICUM*, Linn.—Greece, Ionian Islands, Asia Minor; figured in Bot. Mag., t. 30; Red., Lil., t. 276; Reich., Ic. Germ., t. 453, not of Jacquin.]

30. *L. pyrenaicum*.—This is sometimes considered as being only a robust, broad-leaved, large-flowered form of *L. pomponium*, with which plant it agrees very closely in bulb structure, the bulbs being 2 in. or 3 in. in diameter, ovoid, formed of numerous yellow or brown-stained scales.

[*L. PYRENAICUM*, Gouan.—Pyrenees; figured in Red., Lil., t. 145; Reich., Ic. Germ., t. 992. Syn., *L. flavum*, Lam.]

31. *L. callosum*.—A distinct little scarlet-flowered Japanese Lily, recently introduced to our gardens, and evidently by its growth and bulb structure nearly allied to *L. concolor* and *L. tenuifolium*. The bulbs are rarely larger than a Walnut, formed of a few—say ten or twelve—fleshy-white, somewhat fiddle-shaped scales. Our sketch was made from a large but typical specimen from Mr. Bull's stock, but some of the smaller bulbs are more ovoid, and have the closely imbricated, clasping scales, so characteristic of *L. tenuifolium*.

[*L. CALLOSUM*, Sieb. & Zucc.—Japan and Loo Cheo; figured in Fl. Jap., t. 41.]

32. *L. testaceum*.—This distinct plant has a globose bulb when fully grown the size of a large Orange, the broadly lance-shaped, fleshy scales being 2 in. to 3 in. in length, and closely imbricated in freshly-dug bulbs, more open and loose in the old flowering specimens, and whitish in their colour, some of the outer scales becoming rosy-purple on exposure. Large bulbs after flowering

31. *L. callosum* (Japan); from an imported bulb, natural size.

give rise to three or four centres, a not uncommon occurrence, however, in other vigorous-habited Lilies. The plant is unknown in a wild state, and is thought to be a hybrid between the common white *Lilium candidum* and *L. chalcedonicum* or Scarlet Turk's-cap Lily.

[*L. TESTACEUM*, Lindl., Bot. Reg., 1843, t. 11.—A garden hybrid between *candidum* and *chalcedonicum*; figured in Paxt. Mag. Bot., 1843, p. 221; "Flora des Serres," t. 39; Regel Gartenfl., t. 319. Syn., *L. excelsum*, Hort.; *L. isabellinum*, Kunze.]

33. *L. Leichtlini*.—I have not seen the bulbs of this plant, but they are described by Mr. Baker as being "small, perennial, globose; scales few, broad, acute, thick, closely imbricated." *L. Leichtlini majus* is said by Mr. Baker to be a large and splendid deeply-coloured form of *L. Maximowiczii*, of which the Colechester New Plant and Bulb Company sent me a well-developed bulb, from which it

33. *L. Maximowiczii* = *L. Leichtlini majus* (Japan); cultivated bulb, natural size; colour, soft yellow, like an Ash-leaf Kidney Potato.

appears to me, together with what I gather from Baker's description that the whole group will have to be placed under *L. tigrinum*. *L. Leichtlini majus* or *L. Maximowiczii* has a sub-globose or oblate bulb the size of an Orange, and is composed of about thirty broad, closely-imbricating scales of a yellow tint; indeed, the texture of the outer scales is just that of a smooth Kidney Potato. Our figure is an exact representation of a well-developed bulb.

[*L. LEICHTLINI*, Hock. fl.—Japan. Var. 1. *Leichtlini* proper. *L. Leichtlini*, Bot. Mag., t. 5673; Ill. Hort., t. 540; "Flora des Serres," t. 1736; Belg. Hort., 1869, t. 11; Floral Mag., t. 509. Var. 2. *Maximowiczii*. *L. Maximowiczii*, Regel Gartenfl., t. 596. Var. 3. *Pseudo-tigrinum*. *L. Pseudo-tigrinum*, Carrière, Red. Hort., 1867, p. 110, with a figure; "Regel Gartenflora," t. 664.]

34. *L. pomponium*.—A pretty yellow, orange, or red-flowered Lily, similar in habit to *L. ohaleodonicum*, but with narrower leaves. The bulbs are ovoid, formed of closely-imbricated, yellow scales, which vary from 2 in. to 3 in. in length, the whole bulb being 2 in. to 3 in. in diameter.

[*L. POMPONIUM*, Linnaeus.—Lombardy, and the south of France. Syn., *L. pomponium*, Bot. Mag., t. 971; Reich., Io. Germ., t. 991. *L. angustifolium*, Mill. *L. rubrum*, Lam.]

35. *L. tenuifolium*.—The bulbs of this plant are very strong and variable, and when full-grown, perhaps more nearly resemble those of the Indian *L. polyphyllum* than any other species. They vary in shape from being almost cylindrical and very narrow (scarcely thicker than a pencil) to more swollen, fusiform bulbs, 1 in. in thickness and over 2 in. in length. The few waxy-white scales are not only imbricated closely, but firmly clasp each other, just like the infolded central leaves of the American

17. *L. concolor* (China and Japan); natural size, from a well-grown cultivated bulb; colour, white. [See p. 137.]
 35. *L. tenuifolium* (Siberia) from a cultivated bulb, natural size; colour, waxy white.
 16. *L. pulchellum* (Siberia); from an imported bulb, natural size; colour, white. [See p. 137.]

Agaves. The fusiform bulbs of this plant slide into the ovoid form, as seen in the bulbs of *L. concolor* and its varieties, these being intermediate in shape between the elongated bulbs of *L. tenuifolium* on the one hand and the more globose-shaped bulbs of *L. callosum* on the other.

[*L. TENUIFOLIUM*, Fisch.—Siberia. Syns., *L. pumilum*, Red. Lil., t. 378; *L. linifolium*, Hornem.; *L. puniceum*, Sieb.]

In concluding these remarks on Lily bulbs, it may be as well to give a short summary of the whole. Lily bulbs vary in form and colour, according as the soil in which they are grown is dense or porous; but fresh bulbs of all the distinct types or species are easily recognizable, and that even from the earliest stages after propagation by means of seed. The practice of drying off Lily bulbs, however convenient or necessary it may be for trade purposes, is a bad practice, and should never be adopted by cultivators, inasmuch as no well-planted Lily bulb is injured by the rainfall and cold of our climate, although it may be necessary to protect its young growth occasionally. The typical forms of Lily bulbs are ovoid, with closely-imbricated and lance-shaped scales; globose or orange-shaped, with broad, oblong, pointed scales; rhizomatous, having the scales either distributed regularly along the upper part of the rhizome, or gathered together in the form of bulbs at indefinite intervals. The typical scales of Lily bulbs are lance-shaped, or oblong and pointed, some of the Japanese, one European, and several American kinds having much thickened, articulated, or jointed scales. Well-nourished flowering bulbs increase in size by the increment or extension of new buds or growth; if starved, however, the bulbs become absorbed in flowering and of course die. The propagation of Lilies is effected by seeds, bulb-division, planting old bulb scales, or by layering the flowering-stems after having removed the young flower-buds. The Dutch, English, and Japanese have for many years been engaged in producing seminal varieties; hence some of the natural lines of demarcation which formerly existed between the species have become indistinct.

F. W. B.

Water Weeds.—There is a piece of ornamental water at this place quite overgrown with water weeds, which we are anxious to eradicate without having recourse to "mudding the bottom," an operation which is expensive. Will some of your correspondents, therefore, who may have had lakes in a similar condition, tell us how we can best get rid of the weeds? They consist of the American water weed (*Anacharis alinastrum*) and a species of *Chara*; the *Anacharis* is almost overpowered by the *Chara*, which grows densely and rapidly all over the bottom of the lake. All ordinary means for keeping down water weeds, such as cutting and running off the water, and drying them up, have been tried without much effect. Even although the water was run off for two months during the hottest and driest period of last summer, they came up in a short time afterwards as thickly as before. Poisoning cannot be resorted to, owing to the lake being the source of a small stream.—R. G., *Sevenoaks*.

Small Pots best for Early Hyacinths.—I have this season grown large quantities of Hyacinths, and I find that for early kinds large 60-sized pots are the best, both as regards size of spike and bulb—that is, in the case of Hyacinths grown between the 25th of December and the first week in February. Of Hyacinths for exhibition, I know nothing; but for purposes of early decoration give me small pots.—R. GILBERT, *Burghley*.

Filing Canna Seeds before Sowing.—For several years I have sown a collection of *Canna* seeds, but have never been able to get more than some half-dozen plants from each collection. The seeds were usually steeped for twenty-four hours in warm water before they were sown, and yet they refused to vegetate. This year, before sowing them, I filed each seed with a small file just sufficient to break the hard seed case, and now I find that quite 80 per cent. of them are growing.—H. J. C., *Grimston*.

Wintering Alternantheras.—I lift my supply of old plants of these before they get injured by cold, and plant them in boxes filled with light soil; a close frame suits them until they are established, when they are removed to the back shelves of Pine-houses, and in spring they furnish good strong cuttings by the thousand. I strike several hundreds in one box by only filling the boxes half full of soil and inserting the cuttings as thickly as possible, covering them with small glazed sashes or single squares of glass, a plan by which a cutting frame is readily extemporised.—J. G.

Weeping Willows in Spring.—In Mr. Dancer's nursery at Fulham are large beds planted with Weeping Willows, having stems from 8 ft. to 10 ft. high, and heads of long pendent branches reaching nearly to the ground. These are now furnished with myriads of white, woolly-looking buds, which are just beginning to expand, and which, when swayed by the wind, sparkle like silver among the countless, brown, whip-like branches, forming a feature well worth attention at this time of the year.—S.

THE KITCHEN GARDEN.

FORWARDING EARLY CROPS.

Potatoes.—Much may be done between now and May to accelerate early vegetable crops, and there are numerous simple devices for doing so that come within reach of all. We shall speak of the Potato first, as deserving most attention in that way, and also because it is more amenable to such treatment than many other vegetables. A chief point in securing early Potatoes is to begin with early varieties, or varieties that grow early to a moderate size. Of this description is the kind called *Mona's Pride*; there are sorts that ripen as early or earlier, but the cultivator should place it first on his list of earlies on account of the rapid growth of the tubers. It is one of the largest-sized early Kidneys, not producing many tubers to a root, but they are all large. Some of the Early Ashleaves are too prolific for early croppers, producing too many small tubers, unless the sets are disbudded at planting time. For an early crop a south border, or one sheltered in some way on the north side by trees or a fence, is necessary, and it should slope sharply to the sun—be quite steep, in fact—and be composed of rich, light soil. These are important points; the angle of the ground to the sun's rays makes much difference in respect of the temperature of the soil, and a rich, light, and rather dark soil is necessary, because it absorbs the heat quickly, and stimulates growth. Early Potatoes planted in a lumpy, stiff soil, produce no crop worth speaking of compared to those planted in a fine, mealy compost, consisting of peat, leaf-mould, and loam—the refuse, for example, from the potting bench, or old top-dressings of Vine borders, decayed hot-beds, or anything of that kind that will work up into the surface-spit of the border, and make it loose and permeable to the roots of the plants. The 1st of April is almost early enough to plant out Potatoes that have been sprouted in heat, because they are sure to suffer from the slightest frost if not protected. The sets may be planted about March 1 in old trays or baskets, and covered with soil, about 1 in. or 2 in. deep, and placed in any structure warm enough to start them; light is of no consequence until they come up. In a moderate temperature they will have grown about 4 in. by the end of March, and should be at once planted out in rows about 12 in. or 18 in. asunder, and 6 in. between the sets, burying them sufficiently deep to leave the tops of the sprots just peeping through the soil. Only one shoot, and that the strongest, should be left to each set, for the distance between them and the rows will not allow of more; but the chief object of disbudding them to one shoot is to secure good-sized tubers; many stems mean many Potatoes, but small ones. One good stem is worth half-a-dozen weakly ones, and if placed at the above distances apart, a crop very good in proportion to the extent of the ground planted will be the result. The old common Ashleaf produces good tubers in this way, though naturally a small kind; but it is early and of good flavour, and the tops being small may be grown in little space.

Cauliflower.—By potting a few scores of the autumn-sown plants now in 8-in. or 9-in. pots, and growing them on in a cold frame, Peach screen, or other cool structure, plunging the pots in soil or ashes, and planting them out on a warm border about the first week in April, or a little earlier in warm localities, they will head about a month before the other plants of the same sowing, though they may have the protection of handlights all the winter and spring. The plants should be potted loosely in rough, light soil, and while they are under glass they should not be pashed in the least, but simply protected from frost and cold winds, and freely exposed on fine days. Under this treatment they will grow freely without becoming drawn or lanky, and will not be disposed to "button" after being planted out. In many gardens in Scotland, as far north as Aberdeen and Banff, even Cauliflower is produced in this way as early as in the south of England. Any kind of glass protection is extemporised for the purpose, such as an old light or two reared against a warm wall, and the ends closed up from winds with mats or packing of any kind. The Cauliflower, if sheltered from cutting winds, will make considerable growth during the winter, but it needs a little protection overhead also to have good large plants—half-grown, that is to say—fit for going out in April. They should be hardened off by free exposure to the air a week or ten days previous to planting out, and when planted the roots should be disturbed as little as possible, and the plants should be buried up to their collars, as an earthing up, to keep them from being blown about by the wind.

Peas.—The most common way of forwarding these is to sow in small pots or in long, narrow boxes or drain-tiles some time in February, and plant out about the beginning or middle of March on a warm border. A glass structure is not essential to the raising of Peas in this way, as they can be started in a kitchen or warm shed where it is not quite dark, and afterwards hardened off and greened

on window-sills or in some sheltered nook out-of-doors; but if they can have the protection of glass, it is better and more convenient. The Peas should be sown in 5-in. pots, and planted out when 3 in. or 4 in. high. Six good pots will make a row 7 ft. or 8 ft. long across a border, if the balls be opened out a little. The Peas should be buried to within 1 in. of their tops and staked at once. Peas forwarded in this way do not, however, bear abundantly, and it requires many pots to produce good gatherings for a while, or until the next sowing comes in. A more abundant and almost as early a crop may be produced by sowing a single row along the bottom of a south wall. If the soil be of a good, rich character, the fact of fruit trees being on the wall will not affect the growth of the Peas, though of course the latter must grow out towards the sun and be supported by stakes, as in such a situation they get the full benefit of the sun, both roots and tops, whereas when they are sown across the border in the usual way the rows shade each other considerably. By the first method they pod a week or ten days earlier; the row being near to the wall, within 12 in. or 18 in., perhaps partially sheltered from rain, the soil is apt to get dry about the roots should the weather be dry in April or May, and water must therefore be supplied copiously at such times.

Lettuces.—The secret of getting these forward early consists in planting or sowing in a very light and rich, but not a rankly manured soil, and in a warm situation. The Early Hammersmith is still one of the best early sorts, as it is without doubt the hardiest. The worst fault is that it runs to seed early—autumn-sown plants particularly—especially if transplanted at this season. For this reason I always prefer to sow seed, and I feel sure that spring seedlings grow faster and make larger hearts when they are not transplanted. A strip of good soil along the front wall of a hothouse is an excellent place, if there be a sufficient depth of soil, the heat from the wall making a sensible difference in the temperature of the ground for several feet outwards. The seeds should be sown in drills 6 in. apart, and the young plants should be thinned out as soon as they can be laid hold of—first to 1 in. or 2 in. asunder, and the last 3 in. to 6 in. This is not allowing much room, but it is enough to produce small, compact heads. When the plants are growing they should never be allowed to get dry at the roots, but kept constantly moist, in order to encourage a quick succulent growth and early heading.

Radishes.—This crop may be sown under the same conditions as Lettuces, and of course the early frame kinds should be employed. If they can be protected by a cloche or hand-light top, all the better; but the chief point in Radish culture is to thin early to 2 in. or 3 in. apart. The plants begin to make roots immediately, if well thinned. A Radish with a big top is seldom good.

Carrots.—Like Radishes, the tubering of these is greatly accelerated by early thinning, though we frequently see them standing unthinned till the tops are 1 ft. high, and no root to them worth mentioning. Such neglect is the ruin of the crop. They should be thinned partially as soon as they can be easily laid hold of, and, after danger from grub is over, finally thinned out to form 4 in. to 6 in. asunder each way, in the case of the Early Horn varieties, and from 9 in. to 1 ft. with the larger kinds. The Carrot is very easily forced if not subjected to a high temperature, and is not liable to run to seed like a Turnip. They may be sown under glass, or in any warm spot, in a tolerably deep soil, and liberally watered, and thinned as soon as possible. The best early sorts are the French Early Horn and the Early English Horn. The last is the largest and best, but the first is the earliest.

Kidney Beans.—The first crop of these abundantly repays the trouble of forwarding. They should be sown in 4-in. or 5-in. pots, and sushed on in a temperature of 60° or thereabouts till their seed-leaves are fully developed and the second ones are just showing, when they may be planted out in a warm situation, and in rows 18 in. apart, and 3 in. between the plants. It is needless planting out, however, before the weather is warm enough to continue their growth, and this is not often the case before the middle of May in favoured localities, while June is soon enough in the north. A light and warm soil greatly encourages growth and early fertility, and the transplanted crop should be as much favoured in this way as possible.—"Field."

Peas.—In the paper concerning Peas read by Mr. Pavey (see page 120) I observe with surprise that Laxton's Superlative, a notoriously valueless Pea, is mentioned as one of that raiser's best. So far from that being the case, it has not one good point to recommend it, and in a few years will have died out. On the other hand, Omega is described as deficient in flavour; while Omega has been correctly classed as a dwarf *No Plus Ultra*, and is undoubtedly not

only a delicious wrinkled marrow, but in the matter of flavour the best of Laxton's kinds. The classification of Eugenie as a late Pea is quite out of character, as it is one of the earliest of marrows, but although an immense bloomer and producing an abundance of pods, yet these do not more than half fill, and therefore the sort is but little grown. Such a fine new early Pea as William the First is not mentioned in the paper, but a great deal is made of Kentish Invicta. The most favoured kinds for ordinary gardens and for market cultivation are Dwarf Unique, one of Laxton's best dwarf sorts, a first-early Moltm in Parvo, a delicious dwarf marrow; these can be succeeded by Advancer and Premier, and for field-sowing, Harrison's Glory. In succession should come James' Prolific, G. F. Wilson, Veitch's Perfection, and Omega, the whole forming a selection that would give entire satisfaction to any grower; for fine quality added to dwarfness it would be impossible to excel it.—D.

HOSE COLLECTOR.

The accompanying woodcut represents a new self-coiling hose reel lately invented by Mr. Peirce, of Oxford Street, which promises to prove useful in gardens in which India-rubber hose is used in quan-

tity. Under this arrangement, the machine, while being pushed along, picks up the hose evenly, and thus preserves it from being cut or otherwise injured by being drawn across gravel walks and other rough surfaces.—S. C.

Judging Cottage Gardens.—Can you inform me what are the principal points to be considered in judging cottage gardens, particularly allotments, as our society intends giving prizes for the best-kept gardens, and about how often should they be visited?—J. W. L. [According to my view of this subject the objects sought to be obtained are threefold, and may be classed in the following order, according to their relative importance:—(1) To improve the quality and quantity of cottage garden produce. (2) To encourage the cultivation of a better and greater variety of vegetables. (3) To inculcate order, method, and neatness. Taking the divisions as here set down, to the first I should award three points as a maximum, to the second two, and to the third two, making seven in all; but all competitors should be required to cultivate at least a certain minimum number of distinct kinds of vegetables, say not less than six or eight. In judging cottagers' produce, size, if it does not degenerate into coarseness, should be allowed to carry more weight in decisions than is customary or desirable in the case of vegetables destined for better-class tables. The judges should visit the gardens at least three times between the middle of February and the middle of August, keeping of course the time of their intended visits secret.—E. H.]

Keeping Potatoes undug in the Ground.—Owing to the heavy rains which we had this autumn, some Potatoes, not of so much value as others, were left undug from day to day in the hope that dry weather would set in, but in vain, and at last the entrance to the field was closed for several weeks by a huge pool of water, so that the Potatoes had to take their chance until the end of January, when quantities of both President (White Kidney) and Wonderful (Red Kidney) were lifted, washed in a tub, and laid out to dry for storing. Although both second early kinds, the cold wet state of the soil had kept the tubers from starting into growth, and samples of each when cooked were in all respects as sound, as well-flavoured, and as mealy as if they had been lifted at Michaelmas. Both kinds had been ripe more than five months, and during a considerable portion of the time almost covered with water. President is reputed a

delicate Potato, the flesh being of softest quality, pure white, and as mealy as a Regent; whilst Wonderful Red is equally good, with flesh of a yellow colour, and of good flavour. I do not mention this as indicating that it is desirable to allow Potatoes to remain in the ground, but merely record it as an interesting fact.—A. D.

BOILERS AND HOT-WATER PIPES.

In answer to "A. R. H." (see p. 100), I would state, that I had no reason for finding fault with the working of my apparatus. I only wished to guard the inexperienced against falling into the common error of burying connecting pipes in such a position as to render them useless, liable to injury, and subjected to premature decay. As regards the waste of heat by means of long connecting pipes, I could not adduce better evidence than "A. R. H.'s" own words, which show that he has a boiler-heating piping enough for three houses, but really only warming two; more than a third of the pipes is used merely for the conveyance of hot water. Surely this allows an ample margin for improvement, a circumstance by no means altered by the boiler previously in use having proved a failure. But in what way the original "simple and wasteful" boiler could be considered a failure I am at a loss to guess, seeing that by "A. R. H.'s" own showing, when set properly, it is capable of doing all the work of the improved one. Does "A. R. H." consider "simple and wasteful" to be synonymous terms, and must a boiler be complicated to be economical? I have always understood that complicated boilers or machinery of any kind in daily use required skilled labour to keep them in good working order; while, on the contrary, all flues and surfaces exposed to the action of the fire should be so simply constructed that any ordinary labourer would find no difficulty in cleaning them out when required; for, although on the first trial with everything new and clean, all may go well, success will eventually depend on the facility with which they can be worked by ordinary attention. "A. R. H." says that the new boiler burns so fiercely that scarcely any ashes are left; yet the fire lasts any length of time (in one case, twenty-two hours). This seems to be rather a contradiction, as slow combustion and duration of heating power generally go together in saddle, tubular, or any other form of boiler. The connecting pipe mentioned (1½ in.) would have hard work to keep any quantity of full-sized piping up to a heat sufficient for any practical purpose, but in the dimensions given, the work expected to be performed is very small, and the required temperature is not given. I cannot congratulate "A. R. H." on having seen the last of his troubles, if he follow out his resolution to consult advertisements for his information in future operations. In doing this he will probably be more mystified than edified. My own knowledge has been acquired by actual experience day and night in all weathers, and, with lantern in hand, in the charge of a large forcing establishment, one has the opportunity of studying the merits or demerits of rival claims of boilers to superiority in a more practical manner than even the makers themselves. I find boilers generally capable of performing the work allotted to them, but I am frequently defeated on account of the defective arrangement of the pipes and manner of setting, and, above all, by careless stoking, and want of timely attention to the furnace doors and dampers. JAMES GROOM.

Henham.

HOTHOUSE BUILDING AND HEATING.

In a recent issue of a contemporary, a writer makes reference to an article on this subject which appeared in THE GARDEN of December 9, and so alters some of the statements which it contained as to make them express quite a different meaning from that which they were intended to convey. "Among other things," says the writer in question, quoting from THE GARDEN, or pretending to do so, the boiler is to be "capable of heating the whole with ease up to a temperature of about 180° in the coldest weather," leaving the reader to suppose that it is the houses that were to be heated up to that point, whereas it was the pipes that were referred to. The sentence as it stands in THE GARDEN reads thus: "Stipulate that the boiler is to be of sufficient power, not simply to heat so many feet of piping as the maker puts it, but to heat the whole with ease up to a temperature of about 180° in the coldest weather," a piece of practical advice that any gardener will understand, but so rendered in your contemporary, by leaving part of the sentence out, as to be unintelligible. Surely it is not too much to expect one writer to quote another fairly! The same writer ridicules the suggestion that the woodwork should be painted from the first coat to the last on the premises, and not at the works. All that need be said on this head is that the builder can conform to such an arrangement without any trouble, if he be made a condition, and provided that shed-room be found for his men

the work in. We have no difficulty in the matter, at least, and it costs neither party either extra trouble or expense. Buying wood after it has received two coats of paint is worse than buying "a pig in a poke," for it is impossible to tell afterwards whether the wood is red deal or white deal, or only sap-wood; but people will learn to their cost, if they have to take off all the doors and sashes a few months after the house has been finished, to re-adjust them, and make them fit, and this after paying, perhaps, for every foot to be of the best seasoned red deal.—THE WRITER OF THE ARTICLE ON HOTHOUSE BUILDING.

EARLY PRIMROSES.

IN Mr. Frank Miles' remarks upon the different kinds of Primroses (see p. 124) there speaks at once the lover of nature, the artist, and the enthusiastic horticulturist. Age has not yet dimmed his eye with satiety, nor has he got chilled by the formal rules of the florist. If he could drop in here now when the sun is in the western sky, and its rays are flung vertically across the beds of many coloured Primroses, he would be not less pleased than on the occasion of his first visit. Primroses made very strong growth last autumn and are now flowering beautifully; the chief difficulties which they have to surmount are the frequent wet days by which their beauty is much impaired. It is not possible here to have the beds neat and trim as in some gardens for the necessities of trade, and propagation call for constant removals and re-arrangements: and just now I am re-planting the whole, because they are as far as possible grown in colours of white, sulphur, mauve, red, purple, and crimson; and my annual seedlings are selected in colours as they flower, and planted with the others in fresh beds every spring. The earliest flowers give but little seed, and if the transplanting, and necessary dividing be done at once, the plants quickly become re-established ere the later bloom is developed, and the seed crop is not materially affected. Of course in a trade establishment the sentimental must be largely governed by the practical, and whilst many would object to grow Primroses in formal blocks of colour, it is absolutely indispensable where seed is required for trade purposes. I wish it were possible to infuse a portion of Mr. Miles' artistic sentiment into that very prosaic body, the South Kensington Floral Committee; unsentimental as Peter Bell; a Primrose is to them a Primrose, and nothing more. Although one of the loveliest and earliest of hardy garden plants glowing with rich hues and full of beauty it awakens in the breast of these hardened florists no expression of pleasure or delight. They proceed to judge it by their hard and fast lines of form and eye, and if it have no thrum, or its edge be uneven, and its surface ruffled, turn from it with absolute indifference. When men's lives are passed in an atmosphere of Orchids, Ferns, Stove Plants, Roses, Pelargoniums, and similar brilliant and costly flowers, their tastes are hardly attuned to the appreciation of the beauty possessed by simple hardy flowers, much as they may be prized by common folks; even when very perfect forms of Primroses are submitted for their approval such as the pure white Virginia, the gloriously coloured Brilliant, or the lovely Rosy Morn, some member will probably say that "he has as good or better at home." If that be so, how is it that no other Primroses are ever exhibited before the Floral Committee except those grown at Bedford? Lovers of hardy plants on the Floral Committee should attend and protect the reputation of their *protégées*. Mr. Miles still differs from me as to the best time for sowing Primrose seed. In 1875 I sowed what was saved that year directly it was ripe, and the result was it came up most irregularly, and no doubt the few earliest strong plants in the seed-pan smothered many of the latest and probably best seedlings. Only a few flowered the following spring, and these the coarsest and least desirable. To a stranger this would have given the impression that the strain was a bad one, but all have bloomed this spring, and many very beautiful kinds are found among them. When sown in spring I find that the seeds germinate with regularity, and the following spring every plant flowers. Last August I sowed two pans of seed of *Primula cortusoides amœna*, one pan of home-saved, the other saved in the West of England; not one in either case germinated then, but now I see they are coming up freely, and no doubt in a week or two I shall have two pans full of seedlings. This leads me to the conviction that *Primula* seeds

require a season after ripening to become fully matured before germinating. I have seedlings of this beautiful *Primula* that will flower the second time shortly, and the pods from which the seed was saved belonged to flowers that had been fertilized with *Polyanthus* pollen. The variety produced exhibits the influence of the pollen. As to the assertion that "all white Primroses are really *Polyanthuses*," I am astonished that it should have been made. I have an abundance of pure white Primroses that never show the slightest evidence of the *Polyanthus* scape.

A. DEAN.

Bedfont.

FLOWER GARDEN ARRANGEMENTS.

IT may not be out of place at this season to refer to a style of bedding that seems growing in public favour, viz., the admixture of what are termed sub-tropical or fine-foliaged plants with the usual kinds of dwarf flowering plants, using the latter as the groundwork of the masses, and planting the taller growing foliaged plants at more or less wide intervals—according to size—amongst them. In large beds this arrangement gives elevation to the low masses of bright colours, and at the same time relieves and tones down the glare, and produces a more satisfactory effect. If only the larger beds in a large design were planted in this way, leaving the smaller beds to be filled as before with dwarf plants, the effect would probably be better than if too much be aimed at. This style of decoration admits of a good deal more freedom of treatment in parterre gardening than the common way of training the plants all to one level or nearly so—especially in the arrangement of the ground and the shape of the beds. Although it may be applied to the formal geometrical patterns, yet it is more in character, and looks better if treated more naturally, and if introduced in the way of raised beds and undulating glades of turf. There is no better way of setting out such beds than to take a long waggon rope, coil it into the most graceful outlines securing at the same time the size and position that will look best from that particular point from which it will be most often viewed. Where from the nature of surrounding objects it is practicable to adopt a picturesque arrangement, the elevations and depressions should be easy and graceful, not only for the purpose of securing the best general effect, but also with a view to economy in keeping up good order in mowing, &c., afterwards: abrupt elevation not only costs a good deal to keep in order when the work has to be done with scythe and shears, but the turf is more liable to become unsightly in hot weather.

The following are a few of the best mixed arrangements I noted down in different places as they came under my notice last autumn:—(1) *Wigandia caracasana* planted 4 ft. apart, with a carpet of the Variegated Cocksfoot Grass (*Dactylis glomerata variegata*) underneath, broad band of *Geranium Beauty of Calverdale*, and edged with Variegated Coltsfoot (*Tussilago farfara variegata*). The latter is a striking, broad-leaved, hardy plant that dies down and disappears in winter; its creeping underground stems often travel a considerable distance, sometimes coming up in spring several feet away; therefore the young pale buds must be carefully watched for when digging or hoeing is going on. (2) *Ricinus Gibsoni* (one of the most effective of the Castor-oil Plants) planted 3 ft. apart, groundwork variegated *Geraniums*, broad edging of *Viola Perfection*. (3) Tall Castor-oil Plants 4 ft. apart, *Prince's Feather* pegged down as groundwork, and two rows of *Iris Lindeni*, next *Golden Feather* 1 ft. wide, and two rows, nearly flat, of *Echeveria secunda glauca* outside. (4) Scarlet *Geraniums* with *Giant Hemp* 4 ft. apart, and broad band of *Gnaphalium lanatum* outside. This arrangement is only suitable for a large bed, as the *Hemp* will in good soil grow to a considerable height. (5) *Giant Fennel* with the flowers picked off 3 ft. apart, groundwork *Amaranthus melancholicus ruber*, and edging of *Crystal Palace Gem Geranium*, two rows. (6) Variegated *Maize* 2 ft. apart, groundwork *Scarlet Verbenas*, with broad edging of *Leucophytum Brownii*. (7) *Solanum marginatum* 3 ft. apart, groundwork *Coleus Verschaffelti*, edge broad band of *Golden Feather*. This is a very simple but an exceedingly rich combination. (8) *Solanum robustum*, a red-spined variety, 3 ft. apart, *Pink Geranium* groundwork, with broad

band of Cocksfoot Grass and Lobelias mixed round the edge. (9) *Ficus elastica*, small plants from 2 ft. to 3 ft. high, 2 ft. apart, Golden-leaved Geranium Crystal Palace Gem groundwork, edging Iresine Lindeni. (10) *Dracæna indivisa* 3 ft. to 4 ft. apart, according to size; groundwork of dark blue Heliotrope, and broad band of Variegated Mesembryanthemum, with single plants of *Lobelia intermedia*—a very dark-foliaged, scarlet-flowered variety—2 ft. apart along the centre of the Mesembryanthemum. (11) *Canna expansa*, 3 ft. apart, Golden Geranium groundwork, with broad edging of *Coleus Verschaffelti*. This list might be extended very considerably, and various combinations other than those named might be formed with the same materials.

Ferdinanda eminens is a very striking plant of rapid growth, but it must have a sheltered position, as the wind is destructive to its large, handsome foliage. Cannas must have high culture to be of much use the first season from seeds. Soak the seeds in warm water up to 90° for twenty-four hours before soaking. The Blue Gum (*Eucalyptus globulus*), the Giant Hemp, and the Giant Fennel, should be sown now in pots of light, rich soil, and plunged in a hotbed in a close frame or pit. If they be all placed together they may be covered with a sheet or two of brown paper till the seeds germinate, when they will need exposure to light. As soon as they are large enough to prick off, lift the pots out of the plunging material, but leave them standing on its surface for two or three days to harden a little in order that they may not sustain so much check when their roots are disturbed. Pot them singly into small pots in light, rich soil, return them to the hotbed, shade, and keep close for a few days till established. It will probably be necessary, or at least it will be desirable, to shift them again into 48-sized pots, or in some cases to 32's, so as to have good, strong, healthy plants, to put out about the end of May or beginning of June, according to locality. Mixed beds of foliaged plants, or the latter mixed with Fuchsias, tuberous-rooted Begonias, and both the golden and crimson varieties of *Celosia pyramidalis*, are very effective; the golden variety especially comes much brighter in the open air than in pots under glass. Tuberous-rooted Begonias are, I think, destined to become popular favourites both for mixed bedding and for autumn and winter decoration indoors. They are very easily raised from seed, especially if sown soon after it is gathered, and the second year following seedlings make good flowering plants, either for pot culture or for planting out round the edges of mixed beds of fine-foliaged plants or other positions.

E. HOBDAY.

Trollius Fortunei, and Where to Grow it.—There is one *Trollius* which one must have. Most of them are beautiful for a time, but *Trollius Fortunei* is one of the most glorious flowers the land produces, such an orange as a cloud lit by the last burst of the sun when it has passed beyond the horizon to the birth of another dawn; cadmium and rose madder together form the nearest approach on the palette. Try this *Trollius* in the bog garden in deep, turfy loam; in the hot border it would lose its leaves and half its brilliancy, and only show its true grace and fiery beauty in moister places. I first saw this plant at Kew, labelled with a puny little lath stick, growing in the hottest soil and looking miserable. When shall we have a great national botanic garden, with herbaceous plants growing as they ought to be grown, teaching us not merely the dry names of plants but the different modes of growing them. It is right that Kew should tell us how to grow *Disa grandiflora*, but it would benefit a larger number of enthusiasts to know how to grow properly plants within their reach that stand, without protection, an English winter. The labelling in those herbaceous borders at Kew is not to be commended, but the labelling of a certain bed of *Aquilegia* two years ago was a "caution." I suppose there is lack of means to keep these borders in proper order, but now that England-growing plants are asserting their rights, some pressure ought to be put on the authorities to make the collection representative of the great talent of the chief director.—FRANK MILES, *Bingham*.

Cleaning Honesty Pods (*Lunaria biennis*).—One of your correspondents says the outer pods of this plant are easily rubbed off between the finger and thumb; if so, I fear the operator will not have many inner pods to look at after such rough usage. I have grown the plant for decorative purposes for many years, and I find that the best plan is to take each pod when dry in the hand and pick off the outer skin with the finger and thumb, first bending the pod

at the bottom end, and then turning it over and serving the other side in the same manner. It is rather a tedious process, but the beautiful silvery inside is so brittle and easily cracked that it is the only way to get the other pods and seeds away without injuring it. In Herefordshire the common people call it the Money-till. If the seed be planted in August or September, the young plants will be a very fair size by Christmas time; they stand all weathers, and will bloom beautifully and be fit for vase decoration by next September.—C. E. B.

Ripe Strawberries in February.—We made our first gathering of Strawberries on the 16th inst., and after having gathered them, I must confess that I am almost ashamed to own them; certainly they are ripe Strawberries, and in February, too, but except for putting in jellies, or other kindred purposes, or for the mere name of having ripe fruit so early, I can see no real good to be derived from such very early forcing. The variety was Black Prince Improved, but whether it is worthy of the high eulogiums passed upon it by some growers, I am unable to say; it would hardly be fair to pass judgment so hastily after such a sunless winter as we have had, and as they have been forced in a pot Vine-house, where time is more an object than our expectations as to any particular quantity of fruit, perhaps we ought to take share of the blame on ourselves if the results are not exactly what they might otherwise have been. The plants were grown in 5-in. pots, which were thoroughly packed with roots by the end of the first week in July, and I have little doubt that had they been carefully forced, they would have yielded a fair crop of fruit by the end of the month. They have thrown up abundance of flower-spikes, but fertilization is so imperfect that the crop, although in every respect an abundant one, has an ungainly appearance. The second crop of flowers, as is always the case with Black Prince, is doing much better, but what are they compared to *Vicomtesse Héricart de Thury*, of which variety we have promise of a fine crop of good fruit by the second week in March, our usual time to commence gathering for the season?—W. HINDS, *Otterspool*.

Late Grapes.—In the remarks on late Grapes by Messrs. Wildsmith and Peed (see p. 104), there are some points with which I do not quite agree. I do not think that *Lady Downes* does best in a warm house; on the contrary, I have invariably found that when fire-heat was applied scalding was a certain result. The best *Lady Downes* I have ever seen were grown without any fire-heat at all, and where they got plenty of air and light. They will not stand the damp, close atmosphere in which *Black Hamburgs* delight. With regard to the respective merits of *Lady Downes* and *Alicante*, I think, with Mr. Wildsmith, that *Lady Downes* is, in point of flavour, much superior to *Alicante*, but it requires more care to grow it well, and it has not the appearance or size of bunch that *Alicante* has. I do not by any means consider *Lady Downes* second-rate in size of berry. I have often grown it with berries over 1 in. in diameter. Of course, if compared with such coarse-berried kinds as *Gros Colman* it is second-rate, but I do not think *Gros Colman* will ever be a popular Grape, as it requires too much heat, and the flavour is at best only second-rate. Mrs. Pince's *Black Muscat* will never be a popular Grape, as it does not colour well, and it is also a bad setter. I have tried it in every way, cool and hot, moist and dry, pruned early and late, but could never succeed in getting it anything but a dark brown. Were it not for these faults, it would be the best-flavoured and best-keeping Grape in cultivation.—H. H., *Hound House, Surrey*.

— It seems to me to be a mistake for any one to recommend a Grape on the score of general utility, simply on the strength of his own experience, confined, perhaps, to one place. If the testimony of Messrs. Grieve, Wildsmith, and others, as to the superiority of the *Lady Downes* Grape as a keeper wanted confirmation, I should say it might be furnished from hundreds of sources between John o'Groats and the Land's End. With me, *Lady Downes* is the best generally, but especially as a keeper; and it is the best in any place where I have known it receive a fair chance, and I have seen it, or known of its being grown, in many places from near the Grampians to far south of London, and both in the east and west. These remarks refer to the statements of Mr. J. Peed (see p. 104). As to the *Gros Colman* Grape, it is large-berried and fine-looking, but seldom or never well-coloured—at least I never saw a black berry of it anywhere, and it is the coarsest-flavoured Grape I ever tasted, though tolerable enough to any one who has not eaten good Grapes of any kind for some time previous.—J. SIMPSON, *Wortley*.

West's Patent Trellis.—Though this contrivance appears now to be patented, I would state that a trellis of the same kind, except that it was let down by means of chains, was erected here about fourteen years ago, but was never used after the first trial, so far as I am aware, for it was put up before I came here. Each Vine was let down singly, but by connecting the frames with a rod, all could be let down together. In practice it was useless and objec-

tionable, and I had the wires drawn out and fixed horizontally in the usual way, but the main rods still hang by their chains and hinges, and can be seen if there should be any doubt about the matter. The most serious objection to its use was that it had to be shorter than the rafters, in order to leave room to descend, as the Vinery is tolerably lofty, and the rafters are considerably longer than the width of the house.—J. SIMPSON, *Wortley, Sheffield.*

JAPANESE MUSHROOM CULTURE.

ONE of the industries of Japan is the cultivation of Mushrooms, which are exported in large quantities from that country, and some interesting information respecting them is given by Mr. Robertson in his Report on the Trade of Kanagawa, lately issued. The best of the edible species of Mushrooms are known as "Matsutaké" and "Shii-take." The difficulties attendant on preserving the former kind almost exclude them from the market for export; for not only do they decompose very rapidly, but even when successfully dried are nearly tasteless, and thus useless in cookery. The Shii-take species, however, have this peculiar excellence, that, though all but tasteless in their raw state, when they are dried they have an extremely fine flavour. The quantity that grows naturally on the decayed roots or cut stumps of the Shii Tree is not sufficient to meet the demand for them, consequently much skill has been brought to bear on their cultivation, notably by cutting off the trunks of the Shii and other trees, and forcing the growth of the Mushroom on them. Different varieties of Oak are most in favour for the cultivation of the Mushroom, the tree known as the Shii giving, however, the best results. About the beginning of autumn the trunk, about 5 in. or 6 in. in diameter, is selected and cut up into lengths of 4 ft. or 5 ft.; each piece is then split down lengthwise into four, and on the outer bark slight incisions are either made at once with a hatchet, or the cut logs are left till the following spring, and then deep wounds, 8 in. long, are incised on them. Assuming the first course to have been pursued, the logs, after having received several slight incisions, are placed in a wood or grove where they can receive the full benefit of the air and heat. In about three years they will be tolerably rotten in parts. After the more rotten parts are removed, they are placed against a rack in a slanting position, and about the middle of the ensuing spring the Mushrooms will come forth in abundance. They are then gathered. The logs are, however, still kept, and are submitted to the following process:—Every morning they are put in water, where they remain till afternoon, when they are taken out, laid lengthwise on the ground, and beaten with a mallet. They are then ranged on end in the same slanting position as before, and in two or three days Mushrooms will again make their appearance. When the logs are beaten so heavily that the wood swells Mushrooms are induced of a more than ordinary large growth. If the logs be beaten gently, a great number of small-sized Mushrooms grow up in succession. In places where there is a scarcity of water, rain-water should be collected in tanks. There is yet another plan. The cut logs are buried in the earth, and in a year's time are dug out and beaten as above described. The Mushrooms thus grown are stored in a barn on shelves ranged along three sides, with braziers lighted under; afterwards they are placed in small boxes, the bottoms of which are lined either with straw or Bamboo mats; these boxes are then ranged on the shelves and all approaches carefully closed. An even degree of warmth is thus diffused. The boxes ranged on the upper and lower tiers are constantly changed, so that the contents of each are thoroughly dried. Another mode of drying is to string the Mushrooms on thin slips of Bamboo, which are piled together near the brazier; the heat is well kept in by inverting a closely-woven basket over them. Dried Mushrooms, which are much liked by the Chinese and largely consumed by the Japanese, retain their flavour for a great length of time, and thus bear transport to any distance very well.

PARIS INTERNATIONAL EXHIBITION OF 1878.

THE horticultural department of this exhibition is to be open from the 1st of May until the 31st of October. A garden has been devoted to it near the Champ de Mars, and in this the different productions will be placed, according to their nature, either under glass, in tents, or in the open air. Prizes are offered for all kinds of garden produce, of which there will be a change every month, and those desirous of exhibiting must notify their intention of doing so six weeks before the commencement of each competition, and also mention the different competitions at which they intend showing, distinctly indicating the number of articles to be shown, together with the manner in which they are to be placed, and the space they will occupy. Fruit and forest trees, and any ornamental plants requiring to be planted in an isolated position or in groups on the lawn, ought to be planted before the 15th of May, 1877, and, if possible, this spring. Glass houses will be placed at the disposal of exhibitors on the condition that they undertake to keep them filled while the exhibition lasts. Examples of methods of cultivation pursued in different countries, or of any system or process which may prove of general interest, are admissible. Large plants or trees difficult to move may be placed at once either in the open air or under shelter. The competitions will be divided into two classes, principal and supplemental; and the highest prizes will be awarded to the principal competitions.

The following is the official list:—First series from May 1 to 15. Principal competition—Azaleas and Conifers. Supplemental—new greenhouse plants of every description and seedlings; hothouse plants such as

Orchids, Cactuses, &c.; intermediate-house plants and those for the decoration of apartments; tender bulbous plants, hard-wooded open-air plants, forced shrubs, Roses, Pæonies, &c. Vegetables and fruits either forced or in season. Second series from May 16 to 31. Principal competition—Rhododendron arboreum and trained fruit trees. Supplemental—hothouse plants such as Orchids, Ferns, &c.; intermediate-house plants such as Azaleas and Calceolarias; hardy plants such as Clematises, Roses, herbaceous plants, Pæonies, Ranunculuses. Forced fruits and vegetables. Third series from June 1 to 15. Principal competition—Orchids and Pelargoniums in flower. Supplemental—hothouse plants of any kind; ornamental-leaved plants, Caladium bulbosum, and every description of half-hardy plants; also hardy herbaceous plants of any kind, and shrubs such as Rhododendrons, Azaleas, Kalonias, Roses, &c.; cut Roses, new plants. Vegetables and forced fruits. Fourth series from June 16 to 30. Principal competition—Roses, Palms, Cycads, and Screw Pines. Supplemental—large-flowered Pelargoniums; hothouse plants such as Orchids, Theophrastias, Marantas, Begonias; intermediate-house plants, such as Orange trees, Verbenas, Calceolarias, Echeverias, New Holland plants; hardy annuals and perennials. Fifth series from July 1 to 15. Principal competition—Zonal Pelargoniums and Gloxinias. Supplemental—useful and Official hothouse plants, such as Orchids, Nepenthes, Caladiums; intermediate house plants, such as tuberous-rooted Begonias, Petunias, Amaryllises; hardy plants, such as Hollyhocks. Fruit and vegetables. Sixth Series, from July 16 to 21. Principal competition—hothouse plants. Supplemental—Gloxinias; intermediate-house plant, such as Lantanas, Petunias; hardy herbaceous plants, such as Pinks, Phloxes, Pentstemons, Cannas, Gladioli, hard-wooded ornamental plants. Fruit and vegetables. Seventh Series, from August 1 to 15. Principal competition—Fuchsias, Gladioli, Hollyhocks. Supplemental—climbing exotic plants; intermediate plants, such as Cape Heath, &c.; hardy plants, such as Dahlias, Lilies, Zinnias, Lobelias, Nasturtiums, Hydrangeas. Fruit and vegetables. Eighth Series, from August 16 to 31. Principal competition—Aroids and arborescent Ferns. Supplemental competition—hothouse plants, such as Orchids, Gesneras, Achimenes; intermediate-house plants, such as Fuchsias, Erythrina, Pelargoniums, &c.; hardy perennial plants, such as Dahlias, Hollyhocks, Pentstemons, Phloxes, Pinks; annuals, such as Balsams, Zinnias; aquatic plants, exotic and native. Fruit and vegetables. Ninth series from September 1 to 15. Principal competition—Dahlias and China Asters. Supplemental—Hothouse plants such as Crotons, Allamandas; intermediate-house plants such as Veronicas, Zonal Pelargoniums; hardy plants such as Tea and other cut Roses; deciduous trees and shrubs. Fruit and vegetables. Tenth series from September 16 to 30. Principal competition—Aralias and Dracaenas. Supplemental—Hothouse plants such as Solanums, Ficuses, Musas, Coleuses; intermediate-house plants such as Fuchsias, Zonal Pelargoniums; hardy plants such as Chrysanthemums, Bamboos; annuals of any kind. Fruit and vegetables. Eleventh series from October 1 to 15. Principal competition—Fruits of all kinds. Supplemental—Hothouse plants; new plants; tender and hardy Orchids, Chrysanthemums. Vegetables. Twelfth series from October 16 to 31. Principal competition—Every kind of vegetable. Supplemental—Ornamental trees and shrubs, both deciduous and evergreen; examples of different methods of propagation; Chrysanthemums and plants of all kinds. Special competitions from May to October—Lawns and Grass plots; groups of trees and shrubs; trellis-work, arches, &c.; and bouquets. For schedules containing full particulars apply to the Commissary-General, by whom the details of each competition are arranged.

NOTES AND QUESTIONS—VARIOUS.

Lonicera fragrantissima in Yorkshire.—This Honeysuckle blooms most profusely every year on a cottage here, and is much prized for its delicious scent. It has not been so early in bloom as it was this year for these last five winters; we picked the earliest sprays the first week in January.—H. J. C., *Tudcaster.*

Echeveria secunda glauca Wintered in a Fruit Room.—Having filled a five light pit with the number of plants which I thought I should require for this next season's planting, I had still 6000 left that I did not feel disposed to throw away, and having an Apple room nearly empty, I had them taken there and spread out thinly on the shelves. When looking over them a few days ago, I found them in the best state of preservation possible, more so than those planted in the pit: abundance of light and air was admitted to the room at all times.—R. NISBET, *Ascarby.*

New Potatoes in Succession.—In THE GARDEN of May 6, 1876 (p. 129) was recorded a method of growing successions of new Potatoes in frames on a bed of dead leaves in 1 ft. of light soil. I followed the directions exactly, and planted the Potatoes on October 17. Every one grew and flourished well till January 29, when the leaves drooped, and in a week all that remained was dying stalks, quite rotten at their base and found to contain (on being split open) small white worms like tiny pieces of thread. I was much disappointed and would be greatly obliged by any information on the subject. Has any one else tried the plan?—J. J.

The Double Poinsettia.—I agree with Mr. Fish that over-propagation has weakened this remarkable plant. I have had two in flower for some time, and their heads of showy bracts certainly last longer than those of the single *P. pulcherrima*; nevertheless I cannot say that they last in beauty double the time, because they do not. Moreover, I do not see that the colouring is any more vivid than that of the old variety; and lastly, to have Poinsettias in flower from November to May is surely one of Mr. Fish's flights of imagination. All new plants and new fruits should be criticised fairly. In this case Mr. Fish has over-shot the mark.—R. GILBERT, *Burghley, Stamford.*

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

WILD FLOWERS ABOUT ROME.

THE interesting article contributed to your columns by Mr. Armitage has recalled very vividly to my memory the pleasantest winter of my life which I spent in Rome eleven years ago, and of which my garden still contains many a bright reminiscence. As I look out of my window and see the yellow stars of the *Calendula arvensis*, I am carried back in spirit to the floral fights and fair faces and battery of bouquets which made the Corso so attractive in the Carnival week; and when the little pink stars of the lovely *Erodium romanum* begin to open, I fancy myself driven out along the Appian Way to a meet of the Roman foxhounds at the tomb of *Cæcilia Metella*. *A propos* of this same tomb, in its immediate vicinity, the Grass of the Campagna is thickly studded with one of the prettiest of the Roman flowers, *Ornithogalum tennifolium*. Its almost stalkless umbels of large, pure white flowers look like a shower of silver stars among the Grass. It has made itself quite at home in my garden here, and increases largely both by bulb and seed. I do not know whether the Vandalism of civilization has entirely denuded the Coliseum of its flora, but when I was there the delicate little *Asphodelus fistulosus* opened its rose-tinted flowers in plenty at the very top of the ruins. It completely loses this rosy tint when grown in our colder and less sunny clime. One of the earliest and prettiest of the Roman flowers is *Crocus biflorus argenteus*. The first time I saw it was on a bright sunny morning in January, when, in company with most of the English then in Rome, I was attending the funeral of poor Gibson the sculptor; its very sweet, white flowers striped with purple on the outside were enameling the graves in every direction. In the high meadows on the right bank of the Tiber, about two miles from the city, the Grass is full of the purple and yellow *Crocus*-like flowers of *Trichonema Bulbocodium* and *T. Columnæ*, and lower down, nearer the river, and also in the grounds of the Villa Doria there are quantities of the greenish-white spikes of *Scilla romana*. In the Villa Doria, too, I well remember the delight with which I gathered the curious, velvety-black and green *Iris tuberosa*, the early and pretty *Orchis aranifera*, and the lovely yellow and red bells of *Cerintho aspera*. In the meadows which skirt the road to Ostia, a few miles out of Rome, *Narcissus Tazetta* is abundant, and I shall never forget the fine wood leading down to the sea at Castel Fusano, with its carpet of *Cyclamen hederifolium* and bushes of *Erica arborea*, and a sweet-smelling pink *Daphne*, I think *D. Fioniana*. The large white sweet-scented umbels of *Allium neapolitanum* are the ornament of the shrubberies at the back of the Pincian, and the blue spikes of *Muscari comosum* and *M. racemosum* are found more or less all over the Campagna. At Genzano I found the beautiful dark blue *Scilla bifolia*, and at Hadrian Villa the pure white variety of *Anemone apennina* was not uncommon. At Ariccia, the banks at the side of the road were covered with a lovely bright blue *Pulmonaria*, which I have never seen anywhere else, and the name of which I do not know; it is so beautiful that I wonder it has never been introduced to English gardens. There was, too, a very dwarf *Senecio*, with large golden-yellow flowers growing plentifully in the bogs of the sulphur springs between Rome and Tivoli, which I admired much, but could not make out. I thank Mr. Armitage much for recalling so many pleasant reminiscences to my mind, and if the accompanying supplement to his list of wild flowers about Rome proves of any interest to him or your readers, I shall be much pleased. *A propos* of the Roman *Crocus*, *C. pusillus* and *C. suaveolens* both grow in the immediate vicinity of the city, and there is a lovely unstriped variety of the former species, which is one of the most delicate flowers I know.

H. HARPUR CREWE.

Drayton Beauchamp Rectory, Tring.

CLEMATIS INDIVISA FLOWERING IN DEVONSHIRE.—Mr. Luscombe sends us from Combe Royal, near Kingsbridge, South Devon, fine flowering specimens of this distinct and very free-flowering Clematis, which is now in bloom in his garden in the open air—the leathery, glossy, dark evergreen leaves being almost as handsome as the flowers. We have several times mentioned the extraordinary merit of this Clematis as a climber in the cool greenhouse at this season, but did not know it was hardy. It may be found useful as a wall plant in less favoured gardens than Combe Royal. It would also, probably, be worth trying in sheltered spots among shrubs. It has no resemblance to the new races of Clematis, or to any other species in cultivation. It is in its native country (New Zealand) a rampant-growing woody climber, festooning trees on the outskirts of woods.

HARDY FLOWERS IN LONDON GARDENS.

SPRING-FLOWERING plants are now very attractive, and notwithstanding the unusual quantity of rain that has lately fallen upon them, they appear to last in good condition, even longer this season than when the winters have been drier. In the Wellington Nursery the Grape Hyacinth (*Muscari racemosum*) is throwing up flower-stems in abundance, and the Pileworts (*Ficaria ranunculoides* and *alba*) are also flowering freely. The pale blue blossoms of *Hepatica angulosa* are being produced in great numbers on well-established plants, and Christmas Roses of different kinds are still very attractive, especially

Broad-leaved Saxifraga (*Saxifraga crassifolia*.)

Helleborus colehicus; this, growing on raised beds at Henderson's, is profusely furnished with deep purple, drooping flowers that even in a cut state last in good condition for a long time. The white, Orange-flower-like *Saxifraga Burseriana* may now be found in blossom; the great Strap-leaved Saxifrage (*S. ligulata*) and *S. crassifolia* are also furnishing quantities of large trusses of white and rosy-coloured blooms in Barr's grounds at Tooting, where may also be seen the Prussian blue and velvety-tipped flowers of *Iris persica* and other kinds of *Iris*. Large beds of Squills (*Scilla biflora*) are also one mass of blue blossoms, and the Golden Plover Primrose and *Hepaticas* of various kinds are equally effective. In Ware's Nursery at Tottenham Dog's Tooth Violets are rapidly opening their blossoms, and associated with them are large beds of the Spring Meadow Saffron (*Bulbocodium vernum*), quite a blaze of bright lilac-purple *Crocus*-like flowers. The spring Starworts (*Triteleia uniflora* and *lilacea*) are now worthy of especial notice, thousands of white and lilac-coloured blossoms being borne above dense masses of healthy green foliage; these *Triteleias* can scarcely be too extensively planted wherever well-drained

Dog's Tooth Violet (*Dodecatheon dens-canis*.) Siberian Squill (*Scilla sibirica*.)

borders are available; this year they commenced blooming in the Tottenham nurseries early in December, and they have ever since been a mass of bloom, a condition in which they will apparently continue for many weeks to come. *Crocuses* of various colours are now in brilliant condition in gardens round London; *C. pusillus*, one of the most interesting among them, is flowering freely at Ware's. Perhaps few hardy plants are more remarkably just now than the dwarf-growing Heaths (*Erica mediterranea alba* and *E. herbacea rubra*), established plants of which are used as edgings for large beds and quarters in the Tooting nurseries, and are just now covered with slender stems densely beset with pink and creamy-white blossoms. To these may be added Primroses of many colours, and the White Hoop Petticoat Daffodil (*Narcissus monophyllus*). At Kew *Anemone pavonia* is bearing numerous rich scarlet, Poppy-like blossoms, which are strikingly effective. S.

NOTES OF THE WEEK.

A VALUABLE EVERGREEN HERBACEOUS PLANT.—We notice by the Long Walk in Kensington Gardens a tuft of the rich green and handsome leaves of the large *Acanthus latifolius* in perfectly fresh condition. Probably the mild season has preserved it so well in a London garden; but it is hardy enough to prove a valuable ornament even in winter, in sheltered, warm gardens. Of its merit as a window plant in winter we have already spoken.

THE SWEET LIME AT COMBE ROYAL.—I have a plant of this growing on a wall here, protected only by a Reed frame in winter; it bears abundantly, and is a really good dessert fruit if gathered in a proper state. It is about the size of the Kumquat, but round and otherwise different from that pretty little Japanese Orange.—**JOHN LUSCOMBE, Combe Royal, South Devon.**

AGAVE ELEMEBIANA IN FLOWER.—In the Cactus-house at Kew a large specimen of this American Aloe is now bearing a spike of bloom from 15 ft. to 20 ft. in height, an altitude which it will in all probability greatly exceed by the time it has completed its growth. The stem at the base is as thick as a man's arm, and being densely covered with erect, greenish-yellow flowers, forms an object at once interesting and striking.—**S. C.**

APPLES AND OTHER FRUIT TREES & ALMONDS.—Almond trees are now everywhere in flower near London, and very beautiful they are, but might they not be profitably supplanted by, or at least associated with, good Apple, Pear, or Plum trees, all of which would, when in bloom, be little inferior in beauty to the Almond, and they would, in addition, yield a crop of useful fruit?—**S.**

NEW SEEDLING VIOLET.—Mr. Lee, of Clevedon, sends us flowers of a seedling Violet, somewhat similar in appearance to *V. canina*, but richer in colour and deliciously fragrant, the individual blossoms being as large as those of *Victoria Regina*, and of good substance. Apart from its beauty and novelty as regards colour, this variety is interesting as being a step nearer the acquisition of a really blue Violet than any we have yet had, and which would in many respects be an acquisition.—**B.**

ORCHIDS AT CHOLMELY PARK, HIGHGATE.—Mr. Michael's collection at Cholmely Park is just now very attractive, *Odontoglossums* and *Dendrobiums* being remarkably floriferous, as are also the different species of *Phalenopsis*, to which a small house is especially devoted. Of *P. Schilleriana* many distinct varieties are displaying their graceful wreaths of lilac-tinted, butterfly-like flowers along with those of *P. amabilis* and *P. grandiflora*. A plant of the rich golden-blossomed *Dendrobium Cambridgeanum* bears three very large flowers.—**B.**

KENSINGTON GARDENS.—It is satisfactory to observe that the labelling of the trees and shrubs in the plantations of these gardens is being gradually extended. Many interesting species have been long overlooked in consequence of the absence of a label, and though exception may fairly be taken to the needlessly large and staring description of the labels in use in our London parks, it is better to have them than none at all. It is to be hoped that this really useful work will be still further carried out.—**R. C.**

AGAPANTHUS MINOR.—This miniature form of the African Lily is now flowering in pots at Kew; the blooms resemble those of *A. umbellatus*, but they are smaller, and the golden-tipped anthers are arranged more closely together. Being of a dwarfier habit than that of *A. umbellatus*, and flowering, as it does, at this season of the year, this small African Lily promises to become popular.—**S.**

KENNEDY MARRIATHIANA.—This old-fashioned greenhouse climber is now flowering freely in Messrs. Osborn's Nursery at Fulham. It produces long pendent stems clothed with trilobed, woolly leaves. The flowers, which are Pea-shaped, are of a soft orange-scarlet colour, and are borne singly in the axils of the leaves. Though an old plant it well deserves a place in every greenhouse, on account of its continuous flowering habit.—**J. G.**

THE BRISBANE LILY (Eurycles australasica).—Quantities of this plant, to which we lately directed attention, are now finely in bloom in the Chelsea Nursery. When better known it will doubtless be extensively cultivated, for in addition to the beauty of its flowers, they continue in perfection on the plant in an ordinary sitting-room for several weeks together; for bouquet-making, too, its snowy blossoms will be found useful.

FRUIT CROPS IN WORCESTERSHIRE.—Judging from present appearances fruit trees of all kinds promise to be abundantly furnished with bloom this season. Apricots, as yet, are only partially in flower. Peaches and Nectarines, recently nailed, are bearing a fine crop of blossom buds, which will not, however, be open for a fortnight yet; and Apple and Pear orchards everywhere, when in flower,

will be a sight worth seeing. The present cold weather will have the effect of retarding flowering, and will therefore act beneficially on fruit trees generally, which, on warm soils, consequently upon the extreme mildness of the winter, are somewhat more forward than is desirable.—**W. COX, Madresfield Court.**

THE "ROCKWORK" NEAR THE SERPENTINE.—We are pleased to notice that some of the malformed bricks, clinkers, &c., which, under the name of "rockwork" covered the ground at the end of the Serpentine, are being removed. Better no "rockwork" than mean paucity; a rock garden is not a leprosy of rubbish spread over the reluctant earth in a garden.

RHOODENDRON TAYLORI.—Plants of this new *Rhododendron* in Messrs. Veitch's Nursery at Chelsea are now bearing large trusses of delicate, rosy-pink, tubular blossoms. For early forcing and furnishing cut bloom during the winter months, this plant, when better known, will doubtless be highly appreciated, owing to its being of good habit and a profuse bloomer; it will also be found valuable for conservatory decoration.—**S.**

ONCIDIUM VARICOSUM.—Large specimens of this Orchid are now in bloom in the Exotic Nursery, Chelsea. Their long, branching flower-spikes, which are abundantly produced, are thickly studded with blossoms of the brightest golden-yellow. This, though not so showy as its variety *Rogersi*, is nevertheless a useful plant, and when seen in such fine condition as the plants in question, strikingly effective.

EARLY OUT-DOOR ASPARAGUS.—Perhaps some of your readers may be interested in hearing that on the 15th of this month, at the residence of my mother, the Dowager Lady Williams, at Tregullow, near here, a fine dish of Asparagus was cut, grown in the open air, without any forcing, and from an old bed. The garden lies on very high ground, and is exposed to north and east winds. The circumstance struck me as being of such rare occurrence, and such a proof of the mildness of the season, as to warrant my furnishing the information.—**FRED. M. WILLIAMS, Gooonrea, Perranarworthal, Cornwall.**

"THE WILD GARDEN."—It is intended to fully illustrate in the best manner the next edition of this book. The author will be grateful to any one who may favour him with photographs or sketches showing aspects of vegetation in wild gardens which have already been successfully established in various places. The author's intention is to collect materials for the illustration of the work during the present year, and at its close to place them in the hands of the best artists with a view to their reproduction.

THE SILVERY ACACIA FLOWERING IN ENGLAND IN FEBRUARY.—Mrs. Col. Wright sends us from Watcombe Park, Torquay, specimens of the beautiful *Acacia dealbata*, now in flower in the gardens there, and concerning which she writes as follows:—"The tree is flowering out-of-doors here; it is about 25 ft. high, and appears to have been planted many years in a sheltered position. I thought it might be interesting to readers of *THE GARDEN* to show that we have a fairly warm climate in this part of England. The May is also out in flower in several parts of the plantations, but for this the warm season we have had may partly account." We have seen this *Acacia* flowering beautifully at Caserta in March, but did not think it would attain such fair proportions and bloom so well with us in the open air in England.

LACHENALIA TRICOLOR.—A well-grown and distinct variety of this plant is now flowering profusely in the Rev. A. Rawson's garden at Bromley Common. Its blossoms are chiefly yellow, but the sepals are suffused with vermilion at the base and tipped with green, the petals being half as long again as the sepals, and tinted with rose on their greenish margins. It forms an effective little plant well suited for greenhouse decoration. The leaves, which are comparatively large and vigorous, are faintly spotted.—**B.**

AMOUNT OF MAIDEN-HAIR FERN USED IN BOUQUETS.—Some idea of the extent to which Maiden-hair Fern is used in Covent Garden for bouquet-making may be gleaned from the fact that Mr. Rochford, of Tottenham, has several large, span-roofed houses entirely devoted to its culture for furnishing fronds in a cut state. The plants are grown in 12-in. pots, and in order to keep up a regular succession, only a portion of them is cut at a time, those which furnish such fronds being subjected to a lower temperature than the rest, by which means the fronds assume a deeper green colour, and last longer after being cut than they otherwise would do.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—The thirty-fourth anniversary festival of this Institution will take place on Wednesday, the 4th July next, the day of the great Rose Show, and Sir Trevor Lawrence, Bart., M.P., has kindly consented to preside on the occasion.

THE SWEET SOPS AND CUSTARD APPLES.

THE Anonas are remarkably handsome fruit trees, natives of South America and the West Indian Islands; but several species are cultivated pretty generally in all tropical countries for their large pulpy fruits, and of late years small consignments of those of *Anona reticulata* or Custard Apple have appeared in Covent Garden Market. There seems, however, to be no regular trade in them; for, like Mangoes, they are only seen now and then. I have tasted these fruits, which are as large as a good-sized Apple; but they have rather hard reticulated or scaly coats, the seeds being embedded in the sweet, yellowish-white pulp inside. The Sweet Sop is the fruit of *A. squamosa*, a native of the Malayan Islands, but extensively grown throughout the East and West Indies. The fruit of this plant is ovate and covered with projecting scales; the rind, which is thick, encloses a luscious pulp, concerning which tastes differ; it appears to be highly esteemed by the Creoles, while Europeans think lightly of it. The fruit grown in the Ludian Archipelago is said to possess a finer flavour than that produced in the West Indies. The leaves of this plant have a very disagreeable odour, and the seeds, according to Royle, contain an acrid principle fatal to insects, on which account they are used in a bruised state as an insecticide. Another species — *A. Cherimolia* — the Cherimoyer fruit of the Peruvians, is nearly allied to the preceding, the fruit being heart-shaped and scaly; this is considered by the Creoles to be one of the most delicious of all fruits, a verdict which Europeans do not confirm. In addition to their fruits, however, the plants of this genus are remarkable for their fragrant foliage and aromatic qualities. The soft compressible wood of *A. palustris* is employed in Jamaica as a substitute for cork; the fruit is called the Alligator Apple, but is narcotic and inedible. The Sour Sop of the West Indies is the fruit of *A. muricata*, and is of considerable size, often weighing as much as 2 lb. It is greenish in colour, the outside being covered with prickles; the pulp is white, and has an agreeable sub-acid taste. The annexed illustration is a reduced representation of a fruiting branch of the common Custard Apple, together with a sectional view of the fruit, showing the dark seeds embedded in the white pulp. The North American Custard Apples are varieties of *Asimina* (*Anona*) *triloba*, and are quite hardy in this country, forming slow-growing deciduous shrubs, and bearing large, brown, leathery-looking flowers. A figure of a flowering branch of *A. triloba* was given in THE GARDEN, Vol. X., 1876, p. 9. We find no records of any of the edible Custard Apples having fruited in this country; perhaps the large size to which the trees attain may preclude, to some extent, the possibility of this occurring very generally; still, as aromatic stove fine-foliaged shrubs, they might prove worthy of a place in collections. A compost of fibrous loam, leaf-mould, and sandstone grit, on a well-drained bottom, suits them admirably, and a copious supply of water at the root is essential.

B. W.

HERBACEOUS PHLOXES.

OF these there are two distinct types in cultivation, viz., the shrubby, and the decussata sections, consisting chiefly of garden hybrids, the latter possessing a more robust growth, and being rather later in flowering than the others. The varieties grouped in the shrubby section are largely cultivated in Scotland as well as in the moister districts of the north of England; but around London, and generally in the warmer and drier south, they do not succeed. This distinction is not sufficiently kept in view by catalogue makers, and therefore failure has not unfrequently been the result, through purchasers having got the suffruticose kinds. On the other hand, the varieties of decussata are largely grown in the south, and they have come to be regarded as valuable plants, not only for the embellishment of open borders, but also for cultivation in pots for exhibition and for decorative purposes. The varieties in both sections are readily increased by division in spring, and by means of cuttings made of the young growth produced from the base of the flowering stems during summer, and especially in July and August. These cuttings soon strike root when placed in light sandy soil in pots, and then transferred to a cold frame, or set on the shady side of a cool-house, and covered with a hand-glass. As soon as rooted, the plants require to be placed in 60-sized pots, using a soil consisting of light loam, sand, and plenty of leaf-mould, and they should then be wintered in a cold frame.

These Phloxes are perfectly hardy; but in times of severe frost it would be wise to cover the frame with mats or some such protecting material; treated in this manner strong, well-rooted plants will be ready for planting out in summer. There is nothing like a bed of Phloxes for showing off the different varieties to the best advantage; but they may also be effectively dotted about a mixed border, where the soil is good. They like a deep, rich, strong loam, in which the panicles of bloom come much finer than when the plants are growing in a light, dry

The Sweet Sop, or Custard Apple (*Anona squamosa*).

soil. The soil should be deeply dug and manured during winter, and then thrown up rough for a time to get well pulverised. Phloxes throw out dense masses of rootlets, and, unless these have abundant material on which to feed, the heads of bloom will be sure to be disappointing. Moisture at the roots is also indispensable, and this is an additional reason for using a good holding loam in the bed to be filled with such plants. As soon as the shoots reach the height of from 12 in. to 18 in., they should be tied to stakes to prevent them from being injured by wind. When the flower-buds begin to open, a mulching of manure will be found of great value, and occasional waterings with manure-water will also be of service. In the southern districts, and, in fact, in the majority of cases in northern localities, Phloxes may be wintered in the open ground with little risk of injury; but it is always best to protect in some way the choicer varieties. It is not often that Phloxes are grown in pots, but as it is now customary to offer prizes for cut Phloxes at summer flower shows, there is no reason why encouragement should not be given to plants so grown, the mode of cultivation being simple enough. The strongest of the newly-struck cuttings should be selected for the purpose; early in spring they should be shifted from the 60-sized pots in which they were wintered to 48-sized or 32-sized, according to the dimensions of the plants. The blooming-pots require to be from 10 in. to 12 in. in diameter, and the next shift should be into these, and as soon as they are re-potted they should be plunged up to their rims in ashes, tan, or in

any suitable material, in a shady position, and on no account should they be allowed to suffer from want of water, or they would in all probability lose their leaves. When the plants come into bloom they should be removed to the conservatory and mulched with manure, after the manner of orchard-house trees, and watered with liquid manure. They will then remain in flower for a considerable time. When they have done blooming they should be set out-of-doors to ripen their growth, after which they should be cut down, and the pots again plunged in ashes in the open ground. When severe weather sets in, a little litter should be shaken over the pots to keep the plants from harm. Here they may remain till spring, and when starting into growth they should be turned out of their pots, the roots trimmed, and then placed in smaller pots, and as soon as these are filled with roots they should be transferred to their blooming-pots; after the second year fresh plants should be used, grown up from cuttings as has just been recommended.

New varieties of tall Phloxes are obtained from seed, but so much difficulty has been experienced in getting it to germinate that many are deterred from attempting to raise seedlings. Frequent failures have occurred from efforts having been made to raise seed in heat; as soon as possible after being gathered it should be sown in a shallow pan or box placed in a cold frame and kept moist. Some of the seed grains will germinate quicker than the others, and therefore the crop will appear successional. As soon as the plants are large enough to handle, they should be pricked off into other boxes for a time, and then they should be planted out in spring. The following list comprises a few varieties of undoubted merit, viz.:—A. F. Barron, amabilis, Comte de Lambertye, Dr. Masters, coccinea, Fairy of the Rhine, L'Avenir, Le Lion, Madame Damesnil, Madame Damage, Mrs. Laing, Madame Caillard, Liervalli (a pretty striped variety), Mons. Malet, Lothair, Professor Koch, Queen of Whites, and Sœur de Trionon. Any nurseryman could supply a selection that could hardly fail to give satisfaction. D.

ORCHID CULTURE IN AMERICA.

I NOTICED a few remarks on this subject in a recent number of THE GARDEN (see p. 601, Vol. X.); I therefore thought that an account of my experience of Orchid culture in New Jersey might not be without interest. In the article to which I allude mention is made of the very different climate in this country from that of England, but it requires a resident of several years to discover how very variable it is. Your correspondent mentioned the long continuance of hot dry weather which we had last summer; that, however, is of rare occurrence without a hot rain-storm, during which the air is saturated with moisture, like the rainy season in the tropics. I would not give much for Orchids plunged in Moss and saturated with water after a week of such weather, and as it usually begins with a violent thunder-storm after a very drying day, the plants would probably be quite full of moisture when it commenced, and the Moss would decay in a day or two; for fire-heat is seldom used from the end of May until October, the sun gleaming out at intervals with tropical heat, and even without this the temperature day and night is over 70°. This is the most difficult time for young growths, and even old pseudo-bulbs will decay in a few hours. The summer before last closely resembled an English summer, being scarcely hot enough to ripen Melons and bring the Egg-plant to maturity in the open air; I kept just sufficient fire to warm the pipes in the Orchid-house every night, and by so doing found my plants much benefited. In the winter we have so much bright sun and dry winds that it is necessary to keep more moisture in the atmosphere, and also to water the plants much oftener than is the case in England; now this continual watering decays the potting material, causing many plants to require fresh potting and shaking out oftener than in that country. Another trouble is the frequent intense cold, which in hothouses condenses the moisture into a thick coat of ice inside the glass, which on melting drops on the plants and spots the foliage. Certainly this disaster can be prevented by double glass, and the house being made warmer with less fire, and also cooler in the summer, but the objection to double glass is that the snow does not melt fast enough and has to be removed, or the house is in partial darkness for a number of days, the removal of the snow not being convenient, or it is frozen quite hard to the wood; some kind of covering might be suggested, but I do not know of anything for the purpose which could be used and easily removed, besides the difficulty of securing it against strong gales, the thermometer, meanwhile, being at zero.

Of course it is necessary to employ thick shades in the summer both to break the sun's rays and also to reduce the temperature; at the same time more ventilation should be given at night than during the day, for it is often several degrees cooler in a shaded house than the outside. We find such plants as *Peristeria* and *Schomburgkia*, which are shy bloomers in England, flower abundantly here, the

former producing strong stems and from thirty to fifty flowers on a stem; *Dendrobiums* also grow and flower freely; while *Cattleyas* flower readily, and would seed plentifully if allowed, but the fine green colour seen in the best English collections is difficult to attain. *Cypripediums* succeed well, the old *C. insigne* being the most useful, flowering profusely, and lasting for months in the winter; we frequently have dozens with two flowers on a stem: it is in much request for cut flowers. *C. Roezli* is another species which is in flower all the year; we have a plant with eleven flower-stems, some of them branched; even if the flowers were not so attractive, the plant is worth growing solely for its fine bright green foliage. *Laelia autumnalis*, *Cattleya citrina*, *Oncidium filipes*, *Odontoglossum Cervantesi*, and *O. Ehrenbergi* thrive well in the Camellia-house, which is kept from 40° to 45° fire-heat; these are all grown on blocks. *Laelia anceps* also succeeds in the same house, but requires a little more heat in the winter to bring the flowers well out. *Disa grandiflora* is quite a success in this house throughout the year: there is a plant here with eight spikes carrying fifty-four flowers, and some of the flowering stems were 3 in. round. Such plants generally last in flower over two months. In the great heat of last summer, I grew these out-of-doors in the summer in a moist shady place, but it was impossible to keep them free from thrips, which came from the wild plants in the neighbourhood. *Odontoglossums* do moderately well, the hot weather being a great drawback to their full development, while the miserable little plants sent from Europe do not permit of their showing to the best advantage: if good showy masses be carefully treated, they grow and flower well. The East Indian species generally prosper, although *Phalaenopsids* do not grow so freely as in Europe; these probably would succeed better in a north hothouse, as we find it necessary to grow both *Coelogyne cristata* and *Lycaste Skinneri* in a north house during summer. *Zygopetalums* are very useful for winter; there is usually a plant or two of these to be found in most private establishments; among them are many superior varieties. I may add that there are but few general collections of Orchids in this country, but there is a growing taste for these lovely plants, hundreds of people with a small house or two growing a few plants, and if successful, often devoting a small house to the purpose; but few have yet arrived at the stage of paying ten guineas for a rare *Cattleya* when they can get a good *C. Mossii* for one.

JAMES TAPLIN.

South Amboy, New Jersey, U.S.A.

Hepaticas from Seed.—These are plants that will repay the trouble of raising them from seed, as thereby a great variety of colour is gained, and we shall soon find multiplied the terrific names given in catalogues to these first glances of the spring. The seed does not germinate till the following spring, but it should be sown when ripe. I have now several pans full of seedlings, which will not bloom till next year though they were sown in April 1875; for all that I shall be well repaid, as the flowers were carefully hybridized, and the pans have required little attention after sowing the seed. Turfy loam mixed about half-and-half with Cocoa-nut fibre is the best compost for sowing all such seed as will have to remain a long time in the pans: this compost does not become sour or consolidated.—FRANK MILES, Bingham.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Weigela rosea Forced.—Plants of this well furnished with flower-buds, potted in autumn, and brought on gradually in the progressive temperature of early forcing-houses, are now lovely objects either for furnishing conservatory beds or in a cut state; their delicate tints associate well with almost any kind of flowers in general floral decorations.—J. G.

Stigmaphyllon ciliatum.—This should be in every stove, however small, inasmuch as throughout the summer and autumn months its beautiful Orchid-like flowers may be had in abundance. They are produced in clusters of from four to five on a strong stalk, which adds to their value in a cut state. Its foliage, too, is very handsome, being beautifully fringed with rich crimson-coloured hairs. It is, in short, one of the few stove climbers that succeed really well when confined to pot culture, and, as such, is well deserving of attention.—J. TAYLOR, *Horticulturist's Magazine*.

The Double Poinsettia.—I quite agree with Mr. Fish's remarks respecting this plant, the constitution of which I ruined in my case through over-anxiety to increase my stock. Consequently it has made but a poor display; still I have every confidence that it will in time give entire satisfaction; and I would even go a step further than Mr. Fish, and say, that we shall have this *Poinsettia* in bloom all the year round. Its heads of inflorescence here are in finer condition now than they were three months ago, and they certainly have more depth of colour than those of the single variety.—RICHARD NISBET, *Asbury Park*.

Triteleia uniflora and Hepaticas under Glass.—How few know the value of *Triteleia uniflora* for forcing! It is only necessary to bring it into the greenhouse whenever it is wanted, and in a short time it will be in full flower. All the garden Hepaticas open their blooms with the same rapidity if suddenly brought into a warmer temperature. The lilac variety of *Triteleia uniflora* is a grand plant for a warm border or raised rockwork.—FRANK MILES, Bingham.

A SUBURBAN MARKET GARDEN.

CONSIDERING the enormous quantities of fruit, such as Grapes, Peaches, Pines, &c., which are annually imported to this country from the Continent and America, it is wonderful how English growers can pay such heavy rents for their grounds as they do. That many who attempt to grow fruit and other produce for market fail, there can be no doubt, but in the majority of cases where the proprietor is well acquainted with his business, and in the possession of sufficient capital to permit his trees and plants to become established and in good bearing condition before he of necessity looks for returns, large profits are made by fruit culture in England. A very important point, especially in fruit growing, appears to be that of adapting certain crops to certain seasons, and growing that class of produce which is most likely to be sought after in the market, even should it have to be sold at a cheap rate. Economising and utilising all available spaces, both indoors and out, is also a matter that receives great attention in all well-conducted market gardens, and is probably the main secret of success. Perhaps in few places near London is this better exemplified than in the gardens of Mr. Yeldam, at Hammersmith, and unusually well is this system carried out indoors, all the fruit

Glazed Fruit Shed in Mr. Yeldam's Gardens at Hammersmith.

houses here being made to produce a crop of some kind during the season when the trees are at rest. There are in all about twenty houses, and they range in length from 100 ft. to 220 ft., and are wide in proportion. Vines form the principal indoor crop in this establishment, and these are well attended to, and look remarkably promising. In the earliest houses the fruit is just now setting, and it is expected to be fit for market at the end of May or early in June. The borders are all outside, well drained, heavily manured during the winter, and copiously watered during the summer. Most of the Vines here have been planted for several years, and are principally trained on the rod and spur system, and are allowed several canes each. A large house, however, is devoted to what Mr. Yeldam terms the long-rod system, which consists in training up young rods from the bottom each year, and removing them as soon as they have borne fruit. By this method a crop of large bunches of Grapes is almost a certainty, but they do not always colour so well as those produced on older canes. Black Hamburgh is the kind grown, and this variety serves both for early and late work. Very large bunches and berries are not sought after, and, therefore, the berries are left much more thickly than would otherwise be the case were large berries desired. The bunches weigh heavier when not thinned too much, and a greater number can be obtained from each Vine. Grapes of this description find a more ready sale than those which are brought

to the highest state of perfection, and although they are, of course, sold at a cheaper rate, they are in the end the most profitable.

The principal late Vinery is a span-roofed one about 220 ft. long, with a glass front and brick wall at the back; a pathway runs inside along the front, and at the back is a border from 12 ft. to 15 ft. wide, planted with Camellias, of which there are in this house thirty-five magnificent specimens, averaging from 12 ft. to 15 ft. high and as much through. All blooms that are sufficiently advanced are cut on each market morning, and, on some occasions, as many as 325 dozen blooms have been gathered at one time. Notwithstanding this, many of the plants are still bearing a fair average crop of unexpanded buds. In early Vineries the Camellia will not succeed, but in late houses they thrive admirably, the Vines affording them shade during the summer, and yet not obstructing the light from them during the winter when they are opening their blossoms. The old double white is the only variety grown in this house, but a few very good specimens of coloured kinds are to be found in other houses about the place. In other Vineries Spiræas, Callas, Dentzias, and immense quantities of Rhabarb are forced, but are removed before the Vines offer so much shade as to injure them. The Spiræas are grown on Mr. Yeldam's grounds in Kent, and are good examples of what can be accomplished in this country under liberal culture, inasmuch as they are flowering equally freely as ordinary imported crowns, which are by many considered indispensable for early forcing. The bulk of the Callas are in flower at Easter, at which time there is a large demand for them, and they invariably realize good prices. The Rhabarb roots are placed closely together in beds on the floors of the houses; a little leaf-mould is cast over them, and they are afterwards covered with mats, which remain on the plants until the stalks are pulled. Rhabarb forced in this way, though not possessing quite such a high colour as that which we usually see in the market early in the season, is much better flavoured, and is quickly purchased by those who study quality rather than appearance.

Strawberries form a very important indoor crop here, about 30,000 plants being forced yearly. The plants are layered in small 60-sized pots during the summer, and are afterwards shifted into 32-sized pots. They then remain out-of-doors until severe weather sets in, when they are moved indoors. This season, owing to the weather being so mild, they have only just been housed. The crowns are remarkably plump and strong, and have the appearance of producing large crops. They are now being cleared of dead leaves and arranged in beds on the floor of a large lean-to house from 12 ft. to 15 ft. from the glass. Here they remain until the fruit is gathered, shelves and similar contrivances being entirely dispensed with; the back wall of the house is covered with Peach trees, which are in excellent condition. Two other large houses are entirely devoted to Peaches, and the trees are now one mass of blossom. Barrington, Violette Hâtive and Royal George are the kinds grown, the latter succeeding unusually well, fruit from 8 oz. to 11 oz. in weight having been frequently gathered from it. Standard Peaches, too, are successfully grown under glass, the house they occupy having apparently at some time been a shed; a glass front and roof have, however, been fixed in it, the spars and rafters of the shed and the boarded back remaining as before. The upright posts which support the ends of the cross rafters are from 10 ft. to 12 ft. apart, and at the foot of each is planted a Vine, the main stem of which is trained along the cross rafter, and from this main rod issue at every 2 ft. or so other rods, which are trained in an upright position. By this means the Vines obstruct very little light from other subjects grown in the house, while they themselves have abundance of light and sun on every side. In the centre of the house and between these Vines are planted the standard Peach trees just alluded to; they are from 15 ft. to 20 ft. high, and nearly as much through, and the branches are just now loaded with blossom. The trees are never pruned, but are otherwise liberally treated, and never fail to produce heavy crops of good fruits. The house in question is 215 ft. in length and 25 ft. wide; the back boarded wall is covered with Gloire de Dijon Roses, one plant alone furnishing 150 ft. of the space;

A number of Camellias and several large specimens of Mock Oranges are growing in this house, the latter bearing yearly quantities of sweet-scented white blossoms, which are eagerly bought by bouquet makers. All available space on the floor and between the trees is covered with Rhubarb, and there is at present such a quantity fit to gather that one would think it could scarcely be disposed of at this time of the year; indeed, a more interesting and profitable house than this I have never seen. Last year 7300 bunches of highly coloured Grapes were cut from it, which would probably yield a remunerative return, even had the house been entirely devoted to them.

The out-door stock at this establishment consists of fifteen acres of fruit trees, comprising Apples, Pears, Plums, and bush fruits, the latter being grown in open spaces between the other trees. No more pruning is done to fruit trees here than is absolutely necessary. When the branches get too thick the most unhealthy of them are cut away, otherwise the pruning knife is never used; yet more beautiful specimens of Pear trees than can be seen here it would be difficult to find; the wood is clean, and thickly set with bloom-buds.

Crocuses are also extensively grown here; they are planted on raised beds in the open ground, and when they come into flower they are lifted in little clumps, their roots tied in Moss, and put into boxes for market. Common yellow, blue, and white are the kinds principally grown, and there is now upwards of half an acre of them in one mass of bloom, presenting a sight that can perhaps be better imagined than described.

C. W. SHAW.

Gooseberry Pruning v. Birds.—I observe (see p. 152) that Mr. Wynn advocates early pruning and protecting the trees from birds afterwards by means of soot and lime. This in a season like the present would, I fear, be a much more troublesome remedy than powder and shot, which not only protects Gooseberry trees, but others which suffer equally from their attacks. Mr. Wynn's remark that the powder and shot frequently do more harm than the birds, only proves that the best of remedies may be misapplied. Any one who shoots right into the heart of a fruit tree of any kind is not fit to be trusted with a gun. Birds invariably settle on standard trees before they attack bush fruits, which, therefore, need not be shot into. As regards the time for pruning, I by no means select March as a leisure period, but when success or failure in so important a crop is dependent on a little extra exertion at that time, I think it should be done even if some ordinary routine work be thereby delayed. Early pruning induces early growth as much in the case of the Gooseberry as in that of any other deciduous tree, and frequently if the retarding process can only be secured for a few days, the crop may escape a destructive spring frost as well as the ravages of birds, which not only injure the crop but the bushes as regards bearing wood for years. I make it a rule never to recommend anything until I am satisfied that it is of practical value, and in this case I would say give late pruning and powder and shot a fair trial, and if your crops prove as abundant as ours have been, the amount of useless wood cut away will be reduced to a minimum, as the trees have enough to do to perfect the crops and fruit-buds for the following season. Cutting away artful annual shoots is not desirable.—J. GROOM.

Vines for a New Vinery.—"Old Subscriber" (see p. 152) should not plant more than twelve Vines, which should be a yard apart; indeed, if it be intended to grow plants underneath the Vines, they should stand 3 ft. 6 in. asunder. This will give ample room for the foliage of the Vine and a fair share of light to the plants. If he can only afford 1 ft. for an outside border, it will be better to do without it, as it will merely act as a receptacle for water from the overflow of the spout, and other water that runs down the front, causing the soil to get sodden and sour, and doing more harm than good. As the Vinery is 12 ft. wide, make the border 6 ft. wide to begin with, and complete the remaining part in two instalments, as required. The Vines will do well without an outside border, provided that inside be kept in a healthy condition. It should never be allowed to become dust-dry, nor yet soured with water; four waterings during the growing season are sufficient—one when the Vinery is closed; a second just before the Vines come into bloom; a third, as soon as the fruit is fairly set, and a fourth when it commences the second swelling. Sufficient should be given each time to thoroughly wet the border through. As the Vines are intended to furnish a midseason crop, Black Hamburghs should form the principal part, the other being Buckland Sweetwater. Too many varieties always end in disappointment.—JAMES SMITH, *Waterdale*.

FLOWERS IN VASES OF GROWING IVY.

THE small-leaved wood or wild Ivy forms a good substitute for Ferns for associating with flowers in vases, a fact well pointed out by Mr. McNab in a former issue of THE GARDEN. It grows well in an ordinary sitting-room if it be carefully taken up from the Mossy banks or trees on which it grows, and its stem roots encouraged by being enveloped in living Sphagnum Moss moistened with water occasionally so as to keep it humid. I have tried this mode of growing Ivy in vases, and have now specimens of it which are fresh and healthy after having been three months in a warm room. It will be found to be excellent for draping Vases in which a few flowers, Grasses, or clusters of berries are introduced. The large-leaved Irish Ivy, or that from dry walls, trees, or rocks, is not so suitable for growing in the manner here indicated as the wild kind, for its rootlets, not being acclimatized, damp off when introduced into a moist medium; hence the small-leaved, wild Ivy, from a moist bank, or a ditch, or brookside, where it roots among Moss and fallen leaves, is in every way preferable. My plan is to select pieces from 1 ft. to 2 ft. in length, choosing those sprays only which have bunches of white rootlets at their lower ends; these I place in a vase, or indeed in any receptacle in which a handful or two of moist Sphagnum has been placed. The sprays are arranged as gracefully as possible over the vase, to which it is sometimes necessary even to tie them in their proper positions. I never have many flowers cut at any one time, but if in my rambles around the garden or elsewhere I meet with a pretty bud or blossom, a tuft of wild Grasses, hips, wild flowers, or clusters of berries, I place them as tastefully as I can into my Ivy-clad vases, and at the same time remove any faded blossoms which they may contain. In this way my vases are an ever-changing source of interest, and somewhat of an index or reminder of the flowers which may be found in bloom at any particular season. During winter and spring, when hardy flowers are scarce, we brighten up our growing Ivy by a few clusters of the scarlet-berried Gladwyn Iris or young, silvery Artichoke leaves, with now and then a Crocus bud, Violets, or a handful of Snowdrops, and perhaps a flower or two of Iris reticulata. The Sphagnum Moss does double duty, since it not only keeps a stratum of moisture-laden air around the roots of the Ivy, but it keeps the flowers in position better than water alone would; and we also fancy that the flowers themselves last longer in beauty than when placed in pure water, which may be because the moisture given off by the Moss counteracts the drying influence of the heated apartment. My experience is that full-sized buds of all bulbous plants are infinitely preferable for cutting to the fully expanded flowers, since they open just as well when their stalks are plunged into the growing Moss as when on the plants, and last in beauty much longer, owing to their being protected from winds and cold rains. The annexed engraving will perhaps give a better idea of our Ivy vase than any description possibly could do. It was sketched in December when the only other vegetation obtainable besides Ivy was a few flowers and buds of the Paris Daisy (*Chrysanthemum Lencanthemum*), berries of the Tree Ivy and Pyracantha, and a few sprays of wild Grasses.

F. W. B.

Cyclamens and Sun-heat.—I have just read with interest Mr. Coruhill's letter (see p. 130) about Cyclamens and sun-heat; I cannot, however, see that the mystery about Cyclamens is cleared up by it. My reason is this:—The whole land of Palestine is covered with Cyclamens, and during the spring months they are one of its greatest adornments. They unquestionably belong to the persicam section, and it is much to the purpose that they are by no means deeply covered with soil. I have a great many in full blossom now which I dug up a few years ago with the greatest ease on the hills of Galilee without the assistance of an implement of any description. It is certain, therefore, that both corn and crown must be perfectly scorched during the summer months; the whole country looks like an arid waste, and the rays of a Syrian sun have tremendous power. The Cyclamens of Greece are quite different from those of Palestine; nothing can be more beautiful than the foliage of *C. hederifolium*, which I have from the island of Zante.—H. EWANK, *St. John's, Ryde*.

FLOWERS IN A VASE OF GROWING IVY.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Chrysanthemum cuttings struck at the end of the year will by this time be well rooted and hardened off; they should be at once moved into 6-in. pots, using ordinary loam made rich with one-third rotten manure and leaf-mould in equal proportions, to which a little sand has been added. There is no grosser-feeding plant in cultivation than the Chrysanthemum; to grow it successfully the soil must be rich, and in its early stages it must never be allowed to become pot-bound; for if this occur, no after treatment will ever impart to the plants their wonted vigour, as the stunted condition the roots get into when confined in little pots has the effect of prematurely hardening the shoots. It will be necessary to decide upon the desired shape of the plants; in most cases it is advisable to adopt two or three forms, but the flat, Mushroom-headed fashion should never be followed. The most generally useful for decorative purposes are plants with a dozen or more shoots, ultimately trained with just as many sticks as will support them. All plants intended to be grown thus, should, at the time of potting, have the points pinched out to induce them to break several shoots; this shape will be found the most suitable for the medium-sized, freest-flowering of the large varieties, and also for the Pompones. Many of the large kinds that produce the finest individual blooms, are not capable of being seen in their best form if many flowers be allowed to each plant; for ordinary purposes, six or eight will be enough on each; for growing in this way, the plants must be also stopped now to cause them to form three or four shoots. Amateurs who are disposed to attempt the production of a few of the finest flowers, may do so by only allowing each plant in a 9-in. or 10-in. pot to carry from one to three flowers; these will be found very effective when in bloom if arranged in the greenhouse amongst the dwarfier growers, relieving the even surface, which is justly held objectionable in a stage filled with Chrysanthemums of nearly the same height. To grow them in this way the young plants now potted should not be stopped at all, but simply trained to a single stem all through the season, allowing it to branch out in the summer near the top, to as many shoots as it is destined to carry flowers. Chrysanthemums are frequently seen but mere shadows of what they are capable of being produced, yet they are easily managed, and well repay a little extra attention.

Cinerarias and Calceolarias.—Cinerarias from the second sowing made late last spring will now be pushing up their flower-stems, and will be benefited by using altogether liquid manure of a moderate strength; this treatment will be found of greater efficacy to the plants than giving it in a stronger state alternately with clear water. If some of these late-sown Cinerarias be removed to a frame placed where it will not be directly under the influence of the sun, the supply of these useful flowers will be considerably prolonged; all the protection they will now require can be given, should a little frost occur, by shaking some litter round the sides of the frame, and covering the lights with a couple of mats. Herbaceous Calceolarias, that have now filled their pots with roots and are pushing up their flower-stems, will have their blooming capabilities much increased by the continuous use of liquid manure; these should be in a warmer place than the Cinerarias, and a vigilant look-out kept to see that aphides do not get established upon either of them.

Pelargoniums.—The earliest-blooming, large-flowered, and fancy Pelargoniums will now be showing their flowers, and as the roots by this time will have taken full possession of the soil, they should be supplied with manure water once or twice a week; if attention in this matter be not paid to these plants, there is a difficulty in keeping the foliage of that dark green, healthy hue which so much enhances their appearance when in flower.

Bedding Plants.—Cuttings of Verbenas, Heliotropas, Ageratums, Petunias, Lobelias, and Fuchsias, should be taken off and put in to strike, as the old plants furnish them of sufficient size; see that they are quite clear from green fly when put in, otherwise they will do little good; should, however, any be found upon them, the best plan is to dip the cuttings in Tobacco-water, washing them in clean water afterwards. Keep on propagating the more tender kinds of bedding subjects, including Alternantheras, Iresines, and Coleuses, until there is not only enough to plant, but a good reserve to fall back upon in case of loss. Dahlias of choice varieties that are intended to be increased by cuttings should now be put in a slight heat; if the roots be placed in a broad, shallow box, with a little soil about them, they can be set near the front lights in a Vinery that happens to be at work, which is much better than the usual practice of putting them on the floor of the Vinery, from which position they are likely to get drawn up weakly; such a house as the above not being available, a frame on a slight hotbed will be found ample for the purpose. Tricolor Pelargoniums, being so much

slower in their growth than the ordinary green-leaved kinds, should, if possible, be kept warmer than the latter, so as to get them up in size before planting-out time, for if not sufficiently large when turned out, the little progress they make causes the season to be half over before they produce the desired display: 50° at night will not be too much for them. The above treatment will answer either for plants struck last summer or for such as were taken out of the beds, cut back, and potted in the autumn. Some annual Stocks should be sown in small pots, dropping half-a-dozen seeds into each; these ought to be stood on a slight hotbed or in a house where there is a little warmth, being careful not to over-water the seeds before vegetating, or the young plants when up until they have acquired some strength, as they are extremely liable to damp, the best preventive of which is to keep them as close to the glass as possible directly they appear aboveground. If well attended to and a little more root-room allotted to them as they require it previous to planting-out time, they will flower in advance of later sowings.

Peaches and Nectarines.—The advanced state of the bloom will render it necessary at once to complete the pruning and nailing. The principal thing that amateurs ought to observe in carrying out this work is to encourage and retain, so far as possible, over the whole surface of the tree an even amount of bearing wood; this is especially necessary in the case of young trees, which are often spoilt by getting the bearing shoots to the upper and outer portion of the branches; this is generally caused by retaining too many strong branches in the centre of the tree, whereas, if they be kept more open, there is room for a uniform quantity of young bearing shoots that can always be had with sufficient foresight. In shortening a young shoot of last summer's growth near the base or centre of the trees, the operator should always bear in mind that there is a twofold object in view—the production of fruit for the current year, and the growth of one or two young shoots that will be laid in during the summer for fruiting next year. The point to which he cuts back should, so far as practicable, be regulated by the most suitable position for the present season's growth to occupy. After the tying and nailing is complete, use every means, as recently recommended, to retard the bloom by keeping the sun from it on bright days.

Peas that were recommended to be sown in turves a short time back, if placed where there was any heat, must be removed shortly after they are up to cooler quarters, otherwise they will be drawn up weakly. A diligent look-out must be kept on Peas that have been sown out-of-doors and are now about breaking through the soil, to see that they are not eaten by sparrows, for if these birds discover them just as they get aboveground, they will frequently destroy a whole crop in a few hours. A little soot dusted over them when damp will preserve them from injury so long as it remains, but being liable to be washed off by the rain, it is better to use the white threads as suggested in a former number for bush fruits.

Seakale, the crowns of which were covered with a few ashes as recommended early in the winter, should now have about 10 in. of this material placed over them, as they will shortly begin to grow, and, so treated, will blanch perfectly and be found superior to any forced Kale. When of sufficient size to use, all that is required is to remove the ashes, cut the young shoots off at the tops of the crowns, and subject them to a slight washing, which will free them from the ashes. The stools may remain where they are to make growth for another season; they will need no further attention except the keeping of the ground free from weeds, and cutting out the flowering stems which will be pushed up during the summer.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

March 5.—Potting Gazanias, Chrysanthemums for bedding, and various kinds of Verbenas. Shifting Daphnes, Cherozemas, and Camellias into larger pots, using a compost of loam, peat, sand, leaf-soil, and cow manure for the latter. Potting off young Egg-plants, and re-potting Eriosteumons in 1 am three parts, sand and peat one part; also Epaxises and Heaths. Shifting one-year-old Vines into their fruiting pots, using two parts loam and one part manure. Sowing more Sweet Peas, Mignonette, and Radishes; also Parsnips and Musselburgh and Ayton Castle Leeks. Planting out first Melons; also Globe Artichokes and Potato Onions. Pricking off more Lobelias and placing them in a genial moist heat in Vinery; also first-sown Lettuces in heat, and pricking off Humeas. Blocking *Lelia* autumnalis Ruckeri. Putting in cuttings of variegated Pelargoniums, *Begonia parviflora*, and Plumbago; also inserting cuttings of Tree Carnations on hotbed. Earthing up Potatoes in pit. Top-dressing

young pot Vines and large Rhododendrons, the last with peat. Putting Forty-fold and Dalmahoy Potatoes in Mushroom-house to sprout. Digging among Globe Artichokes; also land for first crop of Carrots and Turnips. Manning and levelling Celery land for Strawberry-berries. Returning bare places in pleasure grounds, and levelling up holes in turf about the lawn. Protecting Plums with nets. Putting down shaling over Orchids. Covering new Mushroom-bed with straw. Washing Camellias with strong Tobacco-water to which 2 oz. of soft soap has been added to the gallon. Cutting down all plants of *Erica hyemalis*. Pruning Hybrid Perpetual Roses. Thinning Peaches in second house a little. Giving Strawberry plants guano-water, and pot Vines some Stanlen's Manure. Dusting lime and soot over Plum trees again. Raising first Peach-house to 58° at night and 63° by day; also second Vineries to 65° at night.

March 6.—Potting Crystal Palace Scarlet Nasturtiums, scarlet Lobelias; re-tubbing Jasminums and Passifloras; also potting large Clematises and shifting into conservatory. Dividing and potting Musk; potting young Fuchsias and Coleus. Sowing Scarlet Gem Melons. Planting Jerusalem Artichokes, and preparing to plant Potatoes close to Peach wall; also planting out remainder of autumn-sown Cabbages. Putting in cuttings of *Achyranthes*, *Salvias*, and *Senecio*. Earthing-up autumn-planted Cucumbers. Putting Dahlias into heat, and Lilacs into Peach-houses for forcing. Digging land for main crop of Carrots and second crop of Broad Beans. Clipping Privet and Holly hedges. Stopping Vines and hoeing among Strawberry plants.

March 7.—Potting dwarf Roses, old and young Fuchsias; also *Myosotis*, a few more *Calceolarias*, and all Dahlias that are struck. Shaking out and re-potting standard Heliotropes, and placing them in heat. Sowing *Perilla*. Putting out Cucumber plants, planting Seakale thongs that are sprouted, and Potatoes under the protection of a Peach wall; likewise a few more Bath Cos Lettuce. Pricking off Borage. Shifting *Aerides*, keeping all live roots on top of pot. Shaking out and re-potting *Cypripediums*. Putting in cuttings of *Euphorbia jacquiniæflora*. Putting more Endive in heat. Preparing rough manure for spring Cucumber plants. Earthing-up more Potatoes. Manuring border for seed-beds. Putting a little straw round Rhubarb roots that have started to ward off frost.

March 8.—Potting Azaleas and *Agatha cœlestis*. Putting into heat all spring-struck Verbenas and young Fuchsias. Potting more French Beans for forcing. Sowing *Godetia*, *Clarkia*, *Collinsia*, *Euclide*, *Calliopsis*, *Zinnia*, *Alonsoa*, *Dianthus*, scarlet Stocks, and *Eschscholtzia* in pots, and placing them in cold Vinery; also James's Keeping and Strasburg Onions, Leeks, Sandringham White and Ivory's Pink Celery, Early Horn Carrots, and Early Dutch Turnip, likewise a bed of Radishes under the protection of a wall. Planting Laurels, Roses, Violets, Early Potatoes on south border, and transplanting Canlidower from pots to hand-lights. Putting strings over young Peas to frighten away sparrows. Beginning to give Strawberry plants in pots more liberal waterings. Levelling ground for third crop of Peas. Cleaning Asparagus beds. Thinning Grapes. Painting late Vines. Keeping Muscat-house just coming into flower at 65° at night and 68° by day. East India Orchid-house to 65° at night, and *Cattleya* and *Dendrobium*-houses at 60° at night.

March 9.—Potting Palms and *Panicums*, and also Azaleas that have done blooming, and old Verbenas. Potting off Alyssum and shifting French Beans and one-year-old Vines, the latter into their fruiting-pots. Shifting old Fuchsias that were shaken out a month ago into larger pots. Planting *Cypresses*, Hollies, and other shrubs, and finishing planting all early borders of Potatoes, and getting in main crops of Potatoes; also remaining Horseradish, Sage, and Thyme. Putting in roots of Asparagus for succession, and introducing into heat more scented Verbenas, Lilacs, Ghent Azaleas, Roses, *Dielytras*, *Deutzias*, &c., for conservatory decoration. Putting cases over two rows of Black Prince Strawberry plants, and letting down wall coverings every night. Covering a ridge of Seakale with short manure 15 in. thick. Pruning standard and other Roses. Forking in manure among Artichokes. Thinning Strawberry blossoms and syringing Peach trees on open walls with sulphur-water to prevent mildew and curl. Watering Strawberry plants and French Beans with weak guano-water. Clearing out frames for Dahlias. Raking and clearing Asparagus beds. Clearing out Violet-pit and making it ready for scarlet *Pelargoniums* to be grown on for flowering in pots. Sowing *Victoria Stocks*, Balsams, and Cockscombs in pots.

March 10.—Potting *Vesuvius* and *Christine Pelargoniums* and yellow *Calceolarias* for flowering in pots. Potting off *Chrysanthemums*; boxing off *Salvia fulgens*; and shifting Tree Carnations. Sowing *Virginia Stocks*, *Clintonias*, *Godetias*, and more Turnips and Early Horn Carrots, on Peach border; likewise sowing pickling and other Onions, Leeks, and Parsley. Earthing up remainder of Sea-

kale crowns intended for blanching. Clipping Box edgings and finishing cutting Grass edgings. Digging border ready for *Glaucium*. Stopping Vine shoots that are sufficiently forward for that purpose. Putting pot Vines in warm Vinery, and some little Azaleas into a cool house to retard their blooming. Putting frames over latest-planted Potatoes on leaf-bed. Putting flower-pots over Seakale crowns, and covering them over with soil. Watering Muscat and Hamburgh-house borders; also all Potatoes in frames. Filling Cucumber-pit with fermenting material ready for planting with spring-sown plants.

Orchids.

The new growth of even the more erect-growing varieties of Orchids will be found to produce the foliage naturally in such a way as to prevent any lodgment of water in the heart of the plant, the last-made leaf being near the middle and inclined forward, a position which it retains until another leaf comes up and takes its place, when the former ones assume a more erect posture, and so on until the growth is completed, and the pseudo-bulb or stem becomes harder and less liable to be injured by water lodging in the heart of the plant. The different kinds of *Phalenopsis*, *Saccolabium*, and *Dendrobium*, afford ready examples of this peculiarity or means of self-preservation. Healthy specimens of *Phalenopsis* bearing large, fleshy leaves, may frequently be seen with the last new leaves hanging down almost immediately in front of the plants; this mode of growth is natural, and whenever it occurs, the foliage should not be placed in any other way; but, unfortunately for the plants, many cultivators think otherwise, and whenever the *Phalenopsis*, *Saccolabium*, &c., send out their foliage in the manner described, they are subjected to a kind of torture by means of sticks and matting, whereby each pair of leaves is retained in position opposite each other, and the plants being thus deprived of their natural protection against drip, often lose their middle leaves or become spotted in the centre. The young growths of the greater part of the *Dendrobes* are inclined forward, and even although it may be desirable to have the plants trained upright before flowering, the young growths should not be so arranged until their progress has been completed, some of them are more impatient of being looped up than others, the very worst being *D. Dalhousianum*. This plant, when trained into any other position than that which it naturally assumes while making its growth, is almost sure to lose its growth the first time that water is allowed to lodge in it; hence we so frequently see *D. Dalhousianum* with the remains of a growth only 2 in. or 3 in. long, which should have grown to a length of 4 ft. By far the safer way to deal with most *Dendrobes* is to make basket plants of them, and allow them to grow as they like. The temperatures during March should be—East India or warm-house, from 65° to 70° by day, and 60° at night; *Cattleya* or intermediate-house, 60° to 65° by day, and 55° at night; *Oulotoglossum* or cool-house, 55° to 60° by day, and 50° at night, the higher day temperatures being for sun-heat. Those who have but one Orchid-house should treat it as an intermediate-house.—JAMES O'BRIEN.

The Riviera and its Flowers in January.—The following is a list of shrubs, &c., in flower at San Remo in the open air in January last:—*Habrothamnus tomentosus* (covered with hive-bees), *Eupatorium Maurisii*, *Ageratum mexicanum*, *Salvia cardinalis* (bright scarlet), *S. involucrata*, *S. rosea*, *Datura arborea fl. pleno* (covered with flowers), *Schinus Molle* (in red berry), *Ligustrum lucidum* (in rich black berry), *Chrysanthemum fruticosum*, *Abutilon album*, *Sparmannia africana* (in abundant flower), *Agathæa cœlestis*, *Narcissus Tazetta*, *N. papyraceus*, *Linum trigynum* (one mass of flowers), *Eriocephalum aromaticum*, *Polygala grandiflora*, *Teucrium fruticosum* (flowers light blue), *Jussiaea speciosa*, *Kennerlyia ovata* (flowers white, blue, and pink), *Solanum capsicastrum* (in abundant ripe berry), *Heliotropium peruvianum*, *Lantana crocea*, *L. versicolor*, *Eucalyptus globulus* (in abundant flower), *Echeveria metallica*, *Lopezia floribunda*, *Salvia ianthina*, *Lavendula dentata*, *Ricinus palma Christi* (fruit and flower), *Gazania splendens*, *Clethra paniculata*, *Freyliuia cestroides*, *Helianthemum mexicanum*, *Farfugium grande*, *Sphaeralcea umbellata*, *Templetonia retusa*, *Bignonia capensis*, *Salvia tomentosa* (a gem), *Raphiolepis indica*, *Bougainvillea spectabilis* (just showing its rich purple bracts), *Buddleia madagascariensis*, *Senecio hederacea* (in full yellow flower—climber), *Acacia Farnesiana*, *Achania Malvaviscus*, *Pittosporum Tobira*, *Salvia Hæri*, *Veronica Andersoni*, *Solanum jasminoides*, *S. lanceolatum* (flowers blue).—PETER INCHBALD, *Hovingham Lodge, York*.

Tulipa Greigi.—This was grand at Tottenham last spring: it is like an immense orange goblet, and perfectly hardy; the leaves are beautifully spotted with black.—FRANK MILLS.

SOWING ONIONS.

In heavy soils, in consequence of so much wet weather, there will be some difficulty experienced in preparing land and securing the necessary tilth for seed-sowing, and yet, in the case of Onions, every day's delay after the 1st of March, taking the average of seasons into account, will probably result in a loss of bulk or weight in the produce from a given area, unless one is in a position to irrigate when the dry weather sets in. In a season like the present, land of an adhesive nature will get close or firm enough without much artificial pressure, and where it was trenched in the autumn it should have been loosened up some time ago with a steel fork; but, under any circumstances, land of the character described cannot easily be made into a good seed-bed, and if much trampled on, its condition will become worse. In every garden there should be a few light handy planks or boards about 10 ft. or 12 ft. long and 1 ft. wide; they will not cost much, and if kept dry when not in use, they will last good for many years; and not only will they be of great assistance in carrying out many operations during bad weather in a difficult season like the present, but the work can be done cleanly, and without treading the soil into a pasty mass that will not recover its proper tone again during the season. Where there are planks sufficient to reach across the quarter or plot it is intended to sow with Onions, by marking the land off into 5-ft. beds, with alleys about 1 ft. wide between them, and laying the planks in the spaces to form the alleys, the seeds may be sown almost without a foot going on the soil, and not only so, but the work can be done in a cleanly, expeditious manner. It will be best to draw the drills across the beds, about 9 in. or 10 in. apart, and not much more than $\frac{1}{2}$ in. deep; and, if possible, some compost, consisting of wood-ashes and light, decayed vegetable matter should be used, with which to cover the seeds instead of the natural soil. Unless some such plan is resorted to, the soil, from being saturated with rain, will cake over the seeds, which will have a difficulty in breaking through the crust, and in fact many will not break through at all. During the last few years I have found a considerable advantage from sowing a considerable portion of the Onion crop in the autumn, and transplanting early in spring. In most seasons, under this treatment, the crop is nearly doubled without incurring any more cost; in fact, when you have a good breadth sown in autumn, it is only necessary to sow sufficient of some good keeping kind in spring for late use in the following spring, after the other crop is finished; and there is no occasion to sow only the Tripoli kinds, as any of the better keeping sorts will stand the winter equally well if not sown too early, and the first week in September will in most places be time enough for putting in the seed. It is better, however, to make two sowings in autumn, the larger-growing Tripoli kinds about a week or ten days before such sorts as James's keeping.

E. HOBDAV.

New Potatoes in Succession.—"J. J.'s" failure (see 164), in growing October planted early Potatoes was probably owing to the excessive dampness of the soil and atmosphere this season. In November, December, and January the rainfall was unprecedentedly great, and early Potatoes growing in frames could not get dry air enough to keep either stems or roots healthy. In favourable winter seasons very early Potatoes may be grown with success in frames with a slight bottom-heat, produced by dead leaves. The best system, however, is to grow them in large pots in pits, or houses, where a little heat can be given to dispel frosts or damp; in this way fresh crops may be had very early.—WILLIAM TILLERY, *WUlbeck*.

The Dandelion as a Salad.—When well blanched and mixed with Celery and Endive in the salad-bowl, this forms an excellent salad, and one which is most wholesome. The improved broad-leaved Dandelion is far better than the old form of this common weed. Seed sown in April will furnish strong roots for the following winter's forcing, and a dozen roots put in the Mushroom-house weekly will furnish a good cutting every day. I think more of this Dandelion than Witloof or Chicory; I do not, however, wish to say that these latter roots are not useful. Some palates may object to the bitter flavour of the Dandelion, but others, again, think this its best quality.—H. KNIGHT, *Floors*.

PLATE LXIII.

THE WORM-GRASS.

(SPIGELIA MARILANDICA).

Drawn by H. HYDE.

WHILE, as a rule, it is desirable to give in the series of plates published weekly in THE GARDEN newly-introduced plants for the most part, yet there are plants long since introduced which, from some cause or another, have failed to obtain at the hands of cultivators that recognition to which they are justly entitled. In the *Spigelia marilandica* we have a perfect illustration of this special type. Nearly 200 years have elapsed since it was first brought from the Southern States of America, and where, may I ask, do we find in gardens well-grown plants of it? Rarely, indeed, is it to be met with at all. A glance at the annexed plate will, however, at once indicate that its absence from general culture cannot be attributed to any lack of beauty; for not only does it possess that qualification as regards its blossoms, but its habit is in every way good; from the root-stock or crown of the plant arise numerous square stems to a height of 15 in., or in its native country even 30 in., sufficiently wiry or woody in character to support themselves without any artificial assistance, in addition to which it is, when established, a permanent, long-lived, herbaceous plant. The question naturally suggests itself, Why is it, then, so scarce? In my opinion this arises from several causes. First, the difficulty we experience in getting our North American friends to send us good, strong plants of it; nay, I might go further and say, to send us plants at all. There are scores of glorious things abundant in the North American woods that not one cultivator in a hundred has ever seen, and which if lifted in good, generous masses, would establish themselves and flower freely in this country. My experience of introductions from America is that they come in a most fragmentary condition: to this remark I must make one exception as regards the glorious tufts of *Cypripedium* brought over by Mr. Sturtevant last season, which produced fine, leafy stems 2 ft. high, with a brace of flowers on each. Should these remarks meet the eye of any would-be caterer to the growing demand for these American plants, I trust he will make a note of them, alike for his own benefit and that of the recipients or purchasers on this side the Atlantic. Our want of success with the *Spigelia* may be in some measure attributed to the fact that, like the equally beautiful *Asclepias tuberosa*, it is very late in appearing aboveground; the beginning or end of June is about the time that it shows itself, and in ordinary gardening work the borders have been trimmed over with hoe and rake once or twice by that time, and even with the utmost care the tops of all the young underground growth may be so far destroyed as to be succeeded by a weakly supplementary growth. This operation repeated in two consecutive seasons will result in the plant's complete destruction. Culturally speaking, our Maryland Worm-grass is usually classed amongst bog plants; to a certain extent this is correct. We are, however, apt to associate the idea of a bog with decomposed vegetable matter in a state of saturation. Now this is a condition which does not suit the *Spigelia*. In its native habitats—the States of Pennsylvania, Georgia, and Louisiana—it is met with in comparatively dry localities, where there is an abundance of rich vegetable mould of a dense peaty nature. I believe it likes good, generous treatment, and that as hitherto cultivated, it has been subjected to the very reverse. The finest plant I ever saw was at Comely Bank many years ago, growing in an ancient hotbed alongside of a glorious tuft of the rare Himalayan *Cyananthus lobatus*. Independent of its beauty, the *Spigelia marilandica*, and, indeed, all the other known species, possess valuable anthelmintic properties, which were well known to the Cherokee Indians, and it forms an element in our Pharmacopœia; the valuable officinal principles, though distributed over the whole plant, occur most markedly in the root. In olden times it used to be placed by systematic botanists in the Order Gentianaceæ, but recently it has been referred to the small but well-marked family of Loganiaceæ, to which our *Nux vomica* belongs, and in which, besides the intensely bitter principle of the former Order, there are certain poisonous properties occurring that

render all the plants contained in it something more than suspicious; and to these our plant owes in a very great measure its anthelmintic properties.

JAS. C. NIVEN.

Hull Botanic Garden.

[We have never seen this plant grow and flower freely except in deep sandy peat. It probably would do well on the margins of beds of dwarf American plants.]

THE FLOWER GARDEN.

LILY BULBS.

I HAVE read lately in *THE GARDEN* an interesting series of articles on this subject by "F. W. B.," who quotes at considerable length observations made by Dr. Wallace on the "Bulb growth of Lilies." Among other remarks Dr. Wallace says:—"A third point I wish to mention which I have not solved to my satisfaction, and on which I shall be glad of further information from other cultivators is, Do Lily bulbs make fresh growth every year, the old growth decaying more or less, as does the Crocus?" This has been no uncommon question, though the terms have been varied according to the fancy of the writers. In the first place, I would ask, is a Lily an annual or a perennial, or is it a biennial? The origin of a Lily bulb is a germ or seed-bud. Nature causes this to vegetate and grow the first year, to bloom the second year, and then it dies—leaves, stem, scales, and roots—all perish! Such is the short though brilliant existence of a Lily bulb. If a bulb that has flowered be taken up late in the succeeding autumn, and cut in two vertically, it will be seen that it has within itself three distinct generations, viz., a portion of the old bulb, which has flowered this year, 1877; the whole of a new bulb, which Nature destined to flower in 1878; and a germ or seed-bud, which is intended to grow up to a full-sized bulb, and flower in 1879. At this time, that is, the autumn of 1877, the seed-bud will be so minute as not to be perceptible without the aid of a magnifying glass; but if a similar bulb be taken up in January 1878, and dissected, the seed-bud will then be perceptible to the naked eye, as it will be about the size of a Canary seed, and be found in the axil between the inmost fleshy scale and the base of the new stem. In February it will be six or eight times larger, and will continue to grow until in the next autumn it will be found to be as large as the new bulb was at the same time in the previous year. By a very simple experiment it may thus be proved that the old bulb of this year (1877), after having flowered, and after having all the sap absorbed from its scales for the nourishment of the new bulb, decays and dies. In like manner its successor, the new bulb, flowers the next year, decays and dies; and so on, one generation following the other year after year, and all having emanated from germs or seed-buds. Then how can it be said with truth that the bulb that has flowered this year has ever flowered before? Or, with what truth can it be said that the bulb that has flowered one year will ever flower again?

I have said that if a bulb that has flowered be taken up late in the autumn and cut in two vertically, it will be seen that it has within itself three distinct generations; to this it may be important to add that at no other time of the year does such phenomena appear. If this, then, be steadily borne in mind, many points which at present appear to be wrapped in obscurity, may easily be resolved. Hitherto it has been the habit to call a bulb taken up in October the parent bulb, but this is not, physiologically speaking, strictly correct. The parent bulb at that time is the new bulb, which is within the old one, as the new bulb has just then given birth to a young one in the form of a germ or seed-bud, while the old bulb itself is now on the eve of dissolution. The old bulb, so often called the parent bulb, has no immediate connection with the young seed-bud; the old bulb gave birth to the new bulb, and it is this new bulb that has given birth to the young seed-bud, which will grow up and flower the year after its own parent has bloomed. There is no genus in which the position of the seed-bud varies so much as in the Lily; the greater number originate low down in the centre of the new bulb, within less than $\frac{1}{4}$ in. of the base of the bulb; some originate further from the centre, and others are formed at a distance from the parent bulbs, to which they

are attached by underground or creeping axes. All, however, spring from a similar source, that is, from germs or seed-buds, and these, in October, are of so delicate and tender a nature as to be in the highest degree liable to injury from drying, exposure, or other adverse circumstances.

Dr. Wallace further says:—"When the stem shoots up from the centre of a bulb it opens up and widely separates the old scales and much enlarges the size of the bulb. I have been surprised," he continues, "to find bulbs under such circumstances of the size of a medium Orange when in flower, though when planted they were only as large as a five-shilling piece." This is clearly a mistake; for if it be borne in mind that a Lily bulb has within itself at a certain time of the year three distinct generations, it will be seen at once that it was not the old bulb as large as a five-shilling piece when planted that was found to be the size of a medium Orange when in flower. The bulb that was planted was evidently, from some cause or other, not a well-grown bulb, but being planted in congenial soil it conveyed nourishment to the new bulb which was within it, and this bulb, with the additional aid of liberal culture, grew to the size of a medium Orange, pushing open and widely separating the old scales, which afterwards decayed and died, as Nature had ordained.

There is another point to which Dr. Wallace draws our attention, which, being of the greatest value, is deserving of the amateur's thoughtful consideration. He says:—"In purchasing Lilies I should like to give my orders very early in the season, and I should request that none of the roots be cut off the bulbs, but that they should be sent to me freshly taken up and packed in some moist material. Indeed, some of the Dutch growers," he continues, "recognize this, for though they expose their roots intended for sale to the action of the sun and air to dry the bulbs and give them a colour (according to the custom of the trade), yet they require that the bulbs they purchase shall be supplied to them quite fresh and with the roots uncut. It is manifest," Dr. Wallace further continues, "that a bulb planted (say in October), rooting and drawing its supplies of nourishment, must be in a far better condition to support active growth in early spring and develop a fine head of flowers than one planted in January or February, kept dry all winter, having hardly time given to it to emit a few roots before the stem shoots up and development progresses at a rapid rate. All Lilies ought to be in their places where they are to remain by the end of October."

For these remarks, which are most valuable, Dr. Wallace deserves the thanks of every amateur who desires to possess a fine collection of Lilies. They might indeed, with great propriety, be extended to some of our own importers, who buy bulbs at auctions, thrust them into the ground, and then sell them immediately as established plants! Newly-imported bulbs are not worth a tenth part of the value of bulbs "freshly taken up" out of a respectable nurseryman's grounds, and guaranteed by him as having flowered the previous season. It is comparatively of little consequence what the quality of the bloom may have been, provided it was healthy, and that the leaves and stems decayed and died down gradually in the ordinary way; for it is the new bulb within the old one that is now to be depended upon, and that and its successors may go on, gradually rising in the scale of perfection through judicious culture.

The cutting off of the roots is the source of more evil than can be foreseen or imagined; in such a case, let me again remind your readers, that a Lily bulb, in the autumn, has within itself three distinct generations; and that the third generation is the germ or seed-bud, which is intended by Nature to bloom during the second season. At the time for lifting and re-planting, the seed-bud, as I have shown, is very delicate and tender, and so minute that it cannot be seen without the aid of a magnifying glass. I have also shown, that in some bulbs its position is within less than a quarter of an inch of the base of the bulb. If, therefore, the roots, young as well as old, be cut off, the tender seed-bud is exposed to the drying effects of the atmosphere and other evils, the result of which is that, in nineteen cases out of every twenty its vitality is destroyed. The new bulb, or second generation, may bloom, though not strongly, as it has to make fresh roots; but any chance of future bloom in the seed-bud is completely gone. It is thus

that so many complaints have arisen about imported bulbs; some bloom once, though weakly, and some do not bloom at all. How can they? Dr. Wallace answers the question by showing us, that many are kept dry all the winter, and are planted as late as January or February. "F. W. B." also aids us with this valuable remark, "that all cultivators are now tolerably well agreed that the sooner Lily bulbs are re-planted after they are moved from the soil the better."

DUNEDIN.

COLOURED-LEAVED PLANTS.

THE following is a selection of coloured-leaved plants for general outdoor decoration divided into six sections, viz., White or Silver-grey, Yellow and Cream, Crimson and Red, Green, Black and Maroon, and Variegated; together with the modes of increasing them:—

White or Silver-Grey.

CENTAUREA RAGUSINA COMPACTA.—This is one of the most useful of all white-leaved plants for marginal effect in borders and for ribbon rows; it is more compact in habit and shorter in the leaf than the old *C. ragusina* (candidissima). It is, however, not so easily increased from cuttings as the latter, but it produces seeds much more freely, and although the raised plants from them are not all of the same habit, they are easily sorted out and classified as regards size. Cuttings put in in March root tolerably freely, and make good plants by May. Those kept for stock should be placed in a greenhouse, the temperature of which is about 55° in February, and as soon as they make a few leaves, nip out the points. This will induce them to throw out a number of young shoots, which, if put in a sandy soil on a brisk bottom-heat, will emit roots in about ten days. Care must be taken not to water over the leaves, and the soil must not be allowed to get dry at the bottom.

CENTAUREA RAGUSINA CANDIDISSIMA.—This, the older variety, is easily known by being coarser in the leaf and more deeply lobed; it grows much stronger than the other, and, as has been stated, is easier to increase, and is very useful where large, broad belts are required.

CENTAUREA GYMNOCARPA is a very fine cut-leaved variety, which is useful for forming edgings to large beds of sub-tropical plants. To have it in its best condition, it should be grown in pots, starved, and then plunged out-of-doors in the pots; it is easily increased by means of cuttings, and it also comes very true from seed.

CENTAUREA CLEMENTEI and *C. ARGENTEA PLUMOSA* are both good plants if used for the same purpose as *C. gymnocarpa*. *C. Clementei* comes quite true from seed, which is the best way to increase it, and *argentea plumosa* from cuttings, which require the same treatment as those of *C. ragusina compacta*.

CINERARIA MARITIMA COMPACTA is an excellent plant with which to form different designs in beds. Unlike the old *C. maritima*, this variety is of a dwarf, close, compact habit, not exceeding 12 in. in height, and it can be stopped lower where required; it is easily increased by means of cuttings, which, if struck in March and stopped once, make bushy plants for planting out in May; it comes fairly well from seed, but some are robust in growth, while others come up weakly; therefore, to have plants for a design or ribbon-row to look well, or to be of uniform growth, they must be raised from cuttings, as in the case of *Centaurea ragusina compacta*.

CINERARIA CERATOPHYLLA.—This elegant cut-leaved variety is dwarf in habit, and in addition to its adaptation for beds and ribbon rows, it is strikingly handsome planted singly on a dwarf green surface. The mode of increasing it does not differ from that of other kinds.

CINERARIA ACANTHIFOLIA and *C. ASPLENIFOLIA* are both somewhat tall, robust-growing varieties, and are therefore best planted in belts in front of shrubs, or in rows with taller, dark-leaved plants, such as *Perilla nankinensis*. Both come pretty true from seed, but they are more uniform in growth from cuttings, as has already been described.

SALVIA ARGENTEA.—This has a large, plush-like leaf, and is very ornamental if used for edgings of raised beds or mounds where the leaves have room to display themselves to advantage. It comes quite true from seed, which may be sown either in autumn or in spring, according to the strength the plants are desired to possess. If sown in February, they make good useful plants by May.

ARTEMISIA STELLARIANA.—This, though somewhat spreading in habit, is nevertheless inclined to grow upwards, but if topped and pegged down it is useful for large beds, and makes a good, broad edging plant. It is not so white as the compact varieties of the *Centaurea* and *Cineraria*; on the contrary, it has more of a soft

greyish tint. It is easily increased, as every little piece of it readily emits roots in a few days if placed on a gentle bottom-heat. At the end of summer the same result may be realised by placing them under hand-glasses in a shady place.

GNAPHALIUM LANATUM.—This resembles the *Artemisia* in colour, and will be found useful for several purposes, as it bears clipping and pegging well. It is also, like the *Artemisia*, easily increased.

DROIS MARITIMA is a pretty plant for marginal effect, but being of a somewhat tall habit of growth, it requires to be planted where it can be stopped at the points and pegged down one shoot over the other, when all the laterals growing erect make a neat and pretty edging. Young shoots of it strike early in autumn or spring, care being taken not to water overhead. Cuttings of it struck in autumn make the best plants for planting out the following year.

SANTOLINA INCANA.—This has a pleasing shade of colour, which serves to tone down the brighter tints. It is rather a difficult plant to increase in the autumn if great care be not exercised; while in February cuttings of it in heat in sandy soil, and not kept too close, strike freely, but the plants thus produced are not of much use that season. It makes good edgings, and is also useful for carpet bedding.

CERASTIUM TOMENTOSUM.—This is a good plant with which to form designs in beds or for edgings, as it will stand any amount of clipping, and may be made into any shape. The best mode of increasing it is to put five or six little shoots into small pots in the latter end of summer; give them a good watering, and keep them in the shade until they are rooted, which they will soon be, then move them to a cool, dry frame, in which they may be wintered, and they will be bushy plants for use in the following May.

CERASTIUM BIEBERSTEINI is a little broader in the leaf than *C. tomentosum*, and has rather a stronger habit, but the same kind of treatment suits both sorts.

ACHILLEA UMBELLATA.—This makes good edgings for small beds, forming, as it does, dwarf tufts about 3 in. in height. Its leaves, which are deeply cut, lie thickly one over the other. In order to increase it, it should be divided into small tufts in autumn, and it is a plant that requires to be well rooted when planted out, or it is liable to be die off here and there, and then it becomes patchy.

VERONICA CANDIDA.—This is a useful plant for carpet bedding, its leaf-growth being close and upright, and of a beautiful glaucous-grey colour. It is easily increased by division in autumn, and every shoot will make a plant for the following year.

LEUCOPHYTUM BROWNII.—This is an excellent plant with which to form lines in carpet bedding or designs, possessing, as it does, a peculiar tint of lavender-grey. Cuttings of it should be struck under a bell-glass in spring, but owing to the sparse growth of the plant, they require a season to get them large enough for planting out; after being pegged down they soon push up and fill out the places allotted to them, but they must be pegged in a uniform way in order to insure success in the arrangement.

SENECIO ARGENTEUS.—This is one of the prettiest little plants in its way with which I am acquainted, its leaves being of silvery whiteness. It is rather a scarce plant, but if used for dotting here and there in carpet beds among other suitable colours, it produces a fine effect. Cuttings of it put in in autumn soon emit roots, when they should be potted off singly, and placed near the light on a shelf in a cool greenhouse for the winter.

ANTENNARIA TOMENTOSA.—This, the dwarfest of all plants possessing the same colour, is found to be very useful for carpet bedding, or as a groundwork below other plants. It is easily increased by division at any time of the year, but autumn is best if a quantity of plants of one size be required. It is a fine plant with which to cover mounds or banks.

Yellow and Cream-coloured Plants.

STELLARIA GRAMINEA AUREA.—This is one of the best of plants either for carpet-bedding, for edgings, or designs, as it submits readily to clipping, after which, in a day or two, its bright golden colour is as beautiful as ever. It may be increased in autumn by division in the same way as the *Cerastium*, and it also strikes freely in March on a slight bottom-heat. It should be kept near the glass, and never quite confined, or it will become drawn and weak.

PYRETHRUM GOLDEN FEATHER.—This is so well known that little need be said respecting it; it is a plant that cannot well be dispensed with, inasmuch as in carpet-bedding, ribbon rows, or edgings, it is equally good. It comes quite true from seed, which is the best mode of increasing it. It should be sown in October, and the young plants should be pricked off into pans or pots, and potted off in February if good plants for planting be desired.

PYRETHRUM LACINIATUM AUREUM is of a 'dwarfer' habit than the Golden Feather, and much more lacinated in the leaf, which in spring is of a fine golden yellow; but as warmer weather sets in, it is not equal to the old variety as regards colour; it likewise comes true from seed.

SEDUM ACRE ELEGANS.—This charming little cream-coloured Stone-crop makes excellent edgings for beds, which might also be filled with it. Every little piece of it emits roots freely in autumn; and when struck, the young plants do best during winter in a dry frame, as it is not so hardy as the green kind.

MESEMBRYANTHEMUM CORDIFOLIUM VARIEGATUM.—This is another useful plant of pale creamy-yellow tint, which for carpet-bedding is invaluable. It is easily increased by means of cuttings, put in in pans or boxes in autumn, and wintered on a shelf in the greenhouse. It requires little or no water after the first watering till February; when, after it shows signs of growth, it should be potted off ready for planting out in May.

LAMUM MACULATUM AUREUM is a pretty golden-leaved plant, with a white stripe down the centre of each leaf; where beds are shaded by trees this makes a lovely edging plant, or, better still, in a bed where a silver-grey tinted plant, such as one of the *Cerastiums*, forms the margin. It does not do for carpet bedding, as, if placed in a sunny aspect, it is liable to be attacked by red spider, and soon looks shabby. It is easily increased by means of cuttings, put in in autumn in a cool, shady place, and it should be wintered in a cool, dry frame: the cold cutting winds cause its leaves to shrivel up, and therefore must be guarded against.

LYSIMACHIA NUMMULARIA AUREA is a beautiful, deep golden-yellow-leaved plant, useful for planting in a nook or corner, either on the rockery or as an edging plant in a northern aspect, where it will retain its colour the whole of the season; being naturally of a trailing habit, it requires a little attention to keep it within bounds. Cuttings of it put in a cool, shady place early in autumn strike readily.

TRIFOLIUM REPENS AUREUM.—This is a beautiful golden-leaved form of the well-known *T. repens*. Like the *Lysimachia* it requires a cool aspect, and when used as an edging to beds of *Centaurea* or *Cineraria compacta*, on a grassy bank, it has a fine effect. Every little piece emits roots freely, and therefore it may be easily increased in the autumn.

FUCHSIA GOLDEN TREASURE is one of the best plants that can be used for ribbon rows, or for margins of sub-tropical plant beds, inasmuch as it hardly ever exceeds 18 in. in height, and possesses a fine tint of orange-yellow. Like its ancestor, *Souvenir de Chiswick*, its habit is branching and bushy.

FUCHSIA GOLDEN MANTLE.—A more robust kind than the *Golden Treasure*, with leaves of a fine golden-yellow colour. Both this and the last are easily increased by means of cuttings put in on a slight bottom-heat in February. Plants of one year's growth are best for immediate effect if properly prepared.

CHRYSANTHEMUM SENSATION.—This is a useful, creamy-yellow-coloured plant, which is easily raised from cuttings. These put in in February, and stopped once, make good plants for planting out in May.

COLEUS AUREUS FLORIBUNDUS is a neat, yellow-leaved plant, of remarkably close habit, and one which, if stopped at once, makes bushy plants for fancy beds in summer. Cuttings of it should be struck in bottom-heat, and hardened off by degrees before being planted out.

PELARGONIUM, LITTLE GOLDEN CHRISTINE, YELLOW GEM, and CRUID'S SEEDLING, are all useful varieties: the first is the dwarfest and best as regards colour, but all of them might be used with good effect in the formation of margins in large beds. Cuttings of them should be put in in sandy soil in the open border early in autumn, and they should be potted as soon as rooted, and wintered on shelves in a greenhouse.

THYMUS MARGINATUS ELEGANTISSIMUS.—This is one of the most compact and beautiful of plants, and one that can be used for either carpet bedding or for scroll work. It retains its rich golden tint throughout the summer season, and it is easily increased early in autumn by means of cuttings put in in a cool, shady place, potted off in spring, and kept growing on for use in May.

Crimson and Red.

ALTERNANTHERA AMENA, A. A. SPECTABILIS, and A. SPATHULATA.—These are the most useful plants in this colour for carpet bedding or for use in the shape of lines to divide colours in beds. *A. amena spectabilis* is a little better coloured, perhaps, than the type. *A. spathulata* is somewhat lighter in colour, and when it assumes its true character in summer it has a fine effect. All the *Alternantheras*

are best increased from the young, high-coloured points, put in as cuttings in March on a brisk bottom-heat—the soil should be loam and peat finely sifted, and made very sandy—when they will emit roots in about ten days and make fine plants for use in June. All the *Alternantheras* require to be planted very closely together, both for immediate effect and regularity as regards growth.

AMARANTHUS MELANCHOLICUS RUBER is an annual which makes a fine ribbon row or a mass of colour in a large bed. It comes rapidly forward from seeds sown in March; when sufficiently large it should be pricked off into pans or pots, and when necessary potted off and placed on a spent manure-bed close to the glass to keep the young plants from becoming drawn.

IRECINE HERBSTI SPLENDENS.—This is a selected variety, and is much brighter in colour than *Herbsti*. It is a useful plant either for rows or masses of colour in beds. If kept pinched back, it may easily be kept in a dwarf state. Cuttings of it put in at any time of the year strike readily.

COLEUS VERSCHAFFELII SPLENDENS.—This is also much brighter in colour than the type. It is useful for large beds or ribbon rows, and its colour is improved if the plants be plunged in the pot and set closely together. Cuttings of it put in in February strike freely on a brisk bottom-heat if not kept too moist. When potted off let them have plenty of room, in order that they may be short-jointed and uniform in growth.

Green.

VERONICA REPENS.—This is a half-trailing plant with very small foliage, and for running over raised mounds or beds it will be found valuable, especially as a carpet for such plants as *Cineraria ceratophylla* and others of similar habit. Cuttings of it put in in autumn strike freely in a shady situation placed under hand-glasses.

CERASTIUM ARVENSE is one of the best bright green plants that can be used for carpet bedding or for narrow, divisional lines. It stands clipping into any shape, and may be readily increased in autumn by division and treated as are other *Cerastiums*.

ARENARIA CESPITOSA (Spergula pilifera).—This pretty Grass-like plant has been used with good effect both for lawns and verges, and also for small banks, or anywhere, in fact, where a smooth, flat surface is desired; it, however, requires to be patted down or rolled now and then. The best way in which to rear it is to make a flat bed and dibble in little pieces of it in May, giving them a good watering if the weather be dry. If kept rolled occasionally during the summer it will become dense, and may be lifted and laid down as one would turf.

HYDROCOTYLE MOSCHATA.—This is a small, truly useful, pale green, round-leaved plant, the habit of which is dense and dwarf, scarcely exceeding 2 in. in height. It is a beautiful plant with which to form designs. It is easily increased in autumn by division, and it should be wintered in a frame.

SEDUM LYDIUM.—This is one of the prettiest, dwarfest, and most lovely green plants with which I am acquainted, and it is one which will be found useful wherever a fine emerald green is required. It is increased by division early in autumn, when every little piece will make a plant for the following season.

SAXIFRAGES.—Some of these are also very valuable where fine green tints are required. The best are *S. densa, Sternbergi, adscendens, hirta, hypnoides, and decipiens*. Little tufts of them should be potted singly early in autumn, and kept in a cold frame during the winter.

NERTERA DEPRESSA (the Fruiting Duckweed).—When covered with berries this should be placed in the orange-coloured section, but it is also a neat dwarf green plant when not in fruit. It may be increased by division, and should be wintered on a shelf in a cool greenhouse.

PYRETHRUM TCHIHATCHEWI is a pretty dark green-leaved plant, well adapted for covering banks, sending down as it does a tap root which sustains its verdure even during times of drought. It will also grow luxuriantly under the shade of trees where Grass would die. It is increased by division in autumn when all its little branchlets will be found to be emitting roots, and if potted singly, will make fine plants for the following summer.

SANTOLINA VIRIDIS.—This is, perhaps, one of the best upright-growing plants that can be used for a straight line. Its beautiful pale green leafage and close habit render it useful where well-defined lines are required. It may be increased in autumn and spring—in autumn, in a cool shady place out-of-doors; in spring, by means of cuttings put in a warm greenhouse under a bell-glass.

THYMUS ERECTUS.—This resembles the *Santolina* in its erect habit of growth, but its colour is more sombre—almost, in fact, an invisible

green. Cuttings of it treated like those of the *Santolina* root freely.

TANACETUM VULGARE CRISPUM.—This is one of the handsomest plants with which I am acquainted, either for forming masses of green, or in the shape of individual specimens set on a greyish ground colour, such as that of *Sedum glaucum*. It is increased by division in autumn, when every crown will make a plant.

MELIANTHUS MAJOR.—This handsome biennial, if sown in spring and cultivated during the summer with care, giving it greenhouse treatment in winter, and properly hardening it off before planting it out, makes one of the most effective glaucous green beds that can well be imagined. If managed in this way, it will attain a height of from 3 ft. to 4 ft., and when belted with *Cineraria maritima compacta*, *Pyrethrum Golden Feather*, and margined with *Cerastium tomentosum*; it has a striking effect, especially when viewed from a distance.

Black and Maroon.

COLEUS REFULGENS.—This is the darkest-leaved plant that we have, and one which looks well when used in a mixed bed, with the yellow blotched-leaved *Abutilon*, margined with *Pelargonium Princess Alexandra*. It is increased like other *Coleuses*.

PERILLA NANKINENSIS.—This has long been a favourite, but the rarer form, *P. laciniata*, is however much the best, as it has not such a weedy appearance. Seed of it should be sown in March, and the young plants should be treated the same as those of the *Amaranthus*.

IREFINE LINDENI is useful for ribbon rows or as beltings in large beds. It may also be used for small beds, as it will withstand pinching back well. Like *I. Herbsti*, cuttings of it strike freely at any time of the year; for May planting the best are those struck in February, and grown on in a spent manure bed near the glass.

COLEUS EMPEROR NAPOLEON.—This is a dark-leaved plant, and one about equally as hardy as *C. Verschaffelti splendens*. If plunged in pots the same as that variety it assumes a fine crimson-maroon tint, very distinct from that of any of the others, and it may be increased in the same way.

Variegated Plants.

CHAMÆPEUCE DIACANTHA.—This, the variegated Fish-bone Thistle, is an interesting plant, and one that can be used with good effect. Being of a silvery hue, yellow should be in close proximity to it if on a green ground. Seed of it sown in February and carefully attended to, will furnish good plants by May, but the best for immediate effect are those sown in September, in a border in the open ground, potted up carefully, and afforded greenhouse treatment during the winter.

ARUNDO DONAX VARIEGATA is one of the most stately of silvery variegated, Reed-like plants, and one that can be used either as single specimens or in the form of a mass, if not planted too closely together. It is perfectly hardy, but needs protection in winter from damp; dry Fern fronds or leaves make a good covering for it. It may be increased by division in April, when it emits roots freely and makes rapid growth.

ACANTHOPANAX QUINQUEFOLIA VARIEGATA.—This is a pretty greenhouse shrub, but it is equally well suited for beds or belts. For both purposes plants of two years' growth are best, being about 18 in. in height. In colour it is creamy-white, and it associates well with *Iresine Herbsti splendens* or *Amaranthus melancholicus ruber*. It is increased by means of cuttings put in late in summer under bell-glasses, and also by means of roots; but plants from the latter are generally more tender and weak in growth than those from cuttings, and they do not make such uniform bushes.

ABUTILON NIVEUM AUREUM MACULATUM, with its beautifully spotted and blotched leaves of green, golden-yellow, and cream colour, is very suitable for mixed beds in which *Coleus refulgens* and *Pelargonium Princess Alexandra* are planted alternately. Cuttings of it made either from tops or eyes inserted on a gentle bottom-heat and kept close for a few days with an occasional damping overhead strike readily. They however require to be gradually hardened off, or they are apt to shed their leaves.

COPROSMA BAUERIANA VARIEGATA, with its beautiful shining green leaves broadly banded with creamy-yellow, is useful for margins of large beds or borders. It requires to be pegged down, when it soon grows into shape and forms a very pretty margin. It is easily increased by means of cuttings put in in spring and early in summer, on a gentle bottom-heat under bell-glasses, and not allowed to get too dry.

FUCHSIA SUNRAY.—This is a useful plant and one which, on account of its lovely rose-pink tinge of colouring in the leaf, associates well

with other plants in a group, especially if the latter be margined with a glaucous-green or silvery-grey-leaved plant. Cuttings of it put in in February make suitable plants for planting out in May.

AGATHEA CELESTIS VARIEGATA is useful in scroll work on account of its peculiar tinge of lemon-yellow and close habit. Cuttings of it put in in autumn in a shady place under hand-glasses make the best plants for the following summer's display.

ARABIS ALBIDA VARIEGATA.—This is the best of all the *Arabises* for edgings; viewed from a distance it seems creamy-white in colour. Single shoots of it put into small pots in autumn, and kept in a dry frame during winter, make useful plants the following spring.

ALYSSUM (KONIGA) VARIEGATUM is a useful plant for ribbon rows or edgings for small beds. Small plants of it raised from cuttings put in late in summer and wintered in small pots on a shelf near the glass in a cool greenhouse are best for the following season's planting.

OPHIPOGON JABURAN VARIEGATUS.—This is a pretty Grass-like-leaved plant, and one which, if intermixed with *Festuca glauca*, would have a pleasing effect. It may be increased by division in spring.

DACTYLIS GLOMERATA ELEGANTISSIMA.—This, an excellent variegated Grass, is suitable either for beds or marginal lines. When planted alternately with *Pyrethrum Golden Feather* on the edge of a Grassy bank, it produces a charming effect. It may be increased early in autumn by division, and should be kept in a dry, cool frame during the winter.

FRAGARIA VESCA VARIEGATA is a suitable plant for a rockery in a north-eastern aspect, where its creamy-white-edged leaves are seen to advantage. It also bears fruit, which, if looked for, will be found just underneath the foliage; but it is not of much value. Like ordinary Strawberries it may be increased by means of layering the runners.

POLEMONIUM CERULEUM VARIEGATUM.—This is a good edging plant in a cool situation where it can be kept moist at the root; it also likes shade, the variegated parts being so tender that strong sunlight scorches them up. Cuttings of it struck in autumn make fine plants for next year.

LYSIMACHIA NEMORUM-VARIEGATUM is a beautiful dwarf plant with small bright green leaves finely margined with creamy-white. It makes a good edging plant for beds or borders, and it strikes readily in autumn under hand-glasses in a cool, shady situation.

PELARGONIUMS.—Some of these are useful in this section, especially the white-edged varieties, which answer either for ribbon rows or belts; they also look well in mixed beds with blue, violet, or rose colour. The best of the white-edged sorts are *Princess Alexandra*, *Avalanche*, *Miss Kingsbury*, *Queen of Queens*, *Snow Wreath*, *Waltham Bride*, and *Virgin Queen*. The best of the golden tricolors are *Dr. Masters*, *E. R. Benyon*, *Peter Grieve*, *Mrs. Pollock*, *Miss Goring*, and *Sophia Cusack*. Cuttings of these put in in an open border in September, using rather sandy soil, strike readily; they should be potted as soon as they are rooted, and kept on shelves in a greenhouse during the winter.

ALTERNANTHERA MAGNIFICA, *VERSICOLOR*, *V. GRANDIS*, *AMABILIS TRICOLOR (latifolia)*, *PARONYCHIOIDES*, and *P. MAJOR*, are all useful for carpet bedding, marginal lines, or rows where bright coloured plants are desired, *P. major* assuming a very fine orange shade late in summer.

R. H. B.

Pruning Roses.—The Hybrid Perpetual and Noisette Roses always commence to grow early in February, whether the spring be early or not, particularly those on the *Manetti* stock, that being of a more excitable character than the *Brier*. Many fear that their Roses will suffer on account of the open weather, some of them having already made shoots from 3 in. to 4 in. long. With these the cold, cutting winds in March will make sad havoc; but that is nothing new, the same thing happens every year. The rosarian has therefore little to fear, provided he has not already pruned his Roses. It is bad practice to prune early, and the first shoots can never be depended upon for producing good blooms. Do not ever be persuaded to prune your Roses until about the first week in April, when the damage done by the cold, frosty winds of March will be apparent. I have often seen the young growth of Roses so much injured by cold, cutting winds in April, that a second pruning was necessary about the end of that month. When good Roses are wanted for exhibition, they can only be procured from a shoot which proceeds from firm, well-ripened wood; always therefore prune to a firm, plump, dormant bud in the spring. All young growth that is in any way damaged should be cut out in April. From good wood come good Roses, while unripe,

soft wood produces poor, thin blooms. These observations apply only to Hybrid Perpetuals; Noisettes on walls will not bloom if pruned so severely as Hybrid Perpetuals, because the blooms are produced at the end of each shoot. When the early spring shoots are killed or injured on Teas and Noisettes, they push out again at the base of the damaged shoots; generally two shoots appear, one of which should be rubbed off, and fine blooms will be the result. If these instructions be followed good blooms may be expected, although they may be a few days later than if the trees were pruned earlier.—H. T.

Pelargonium Vanessa.—For some years I have been hybridizing and raising new Pelargoniums, a few of which I sent to Chiswick to the annual trial. Three of these received first-class certificates as hedging plants. Vanessa is one which has been much talked about, and I hope to see it in every garden worth going into. It is

ROSES FROM SEEDS AND FROM GRAFTS.

There is scarcely a garden in England, however small, but what has a Rose or two of some kind or other, and various expedients are employed by many with a view to their propagation, the most common methods of effecting which are either by budding, or by means of cuttings made of the half-ripened wood put in early in autumn. Most people have some knowledge of one or other of these modes of propagating, but there are comparatively few who are acquainted with the art of grafting, which is by far the most expeditious and certain way of increasing the Rose, as by carrying it out now good flowering plants may be had for turning out in May, or if potted on, such as will make strong bushes for blooming the following winter. Although this is the most expeditious way of raising and increasing the stock of this favourite flower, by

A Rose Tree.

a highly-coloured salmon, much flushed with orange and tones of pink, and a long way superior to Forest Hill Nosegay or Lizzie, those two being the nearest approach to it. It is very distinct, and a grand pot plant. I have never tried it as a bedder, but it was in that form when it gained a first-class certificate at Chiswick. When I say that Dr. Denny, Mr. William Paul, Mr. Richard Dean, and many others well acquainted with Pelargoniums, have spoken in the highest terms of it, I think I need hardly say more.—FRANK MILES.

A Rose Tree.—In days when the extension system for Vines is so much talked about, an illustration of a huge Rose tree may not be without interest. This Rose (Laure de Besançon) grows in the garden of M. Catelle, Avenue du Chateau, in the Commune of Lilas, near Paris; it is nearly 20 yards in circumference. In the season it is said to be covered with thousands of Roses, but of their character we cannot speak; later on, however, we or some of our Rose-growing correspondents may be able to give a fuller account of it.

far the most fascinating is that of obtaining it from seed, and those who have hitherto only worked their Roses in the ordinary way can have no idea of the absorbing interest there is always attaching to a number of seedlings when under the care of those who really love their gardens, and take a delight in the beauties of Nature. The pleasure of raising seedlings is greatly enhanced by the uncertainty of what colours they will furnish, and the expectations raised as to what they will turn out to be, whether anything like the parent from which the seed was gathered, or an entirely new kind, as is most likely to be the case. To whet the appetite of those who may be desirous to embark in raising seedling Roses, and to give them zest for their work, it is only necessary for them to know that many of the best kinds now before the public were obtained from seed saved from plants, the flowers of which had not been manipulated in any way further than what the bees

had done in their busy work of collecting honey, in which operation it has been wisely ordered that they carry the pollen with them, and thus add to our floral wealth.

Saving and Sowing Rose Seeds.

The exceedingly dry summer, and the fine autumn that succeeded, favoured to an unusual degree the setting of Rose flowers and the ripening of seeds, and as these are on that account still to be found in abundance on the plants, to many an excellent opportunity is afforded of collecting and sowing the same. The best way of doing this is to gather the hips, naming each kind as it is picked from the plants, that, when they are sown and come up, it may be seen at a glance if they differ in foliage or habit, or have any peculiarities distinct from the parent. Keeping them separate, and naming them in this way, add much to the interest of seedling Roses, as the slightest variation amongst them is sure to be noticed in the close watching they receive as they continue to develop themselves. There is something so attractive and interesting in the pursuit of raising plants from seed, especially when the aim is to produce new varieties, and such a feeling of self-satisfaction when that object is attained, that I strongly commend this branch of gardening to all who are so favoured as to have the opportunity and spare time to devote to so pleasant a pastime. It is not likely, however, that those who once take it up will rest satisfied with just gathering a few seed-pods they may find here and there, and depend for success on any accidental occurrence that may take place through the agency of bees; and it may therefore be well to say a few words as to the proper course to take in order to render the work of raising new varieties of the queen of flowers a matter of some certainty. This may be done, and certain intermediate shades of colour produced, by working from those of an opposite character, it being one of Nature's laws that like produces like, both in the animal and vegetable kingdoms. In the case of a Rose, or any other flower, it may be roughly stated that the result of fertilizing a red with the pollen of a white, or *vice versa*, would, if seeds were saved and plants raised therefrom, afford several shades of pink which would be intermediate between both parents. If the object, then, be to produce these colours, that is the way to commence operations, and the same with yellows, crimsons, or any other colour, always choosing the best-shaped flowers and the most approved kinds on which to work. Yellow is a colour in which we are sadly deficient, and it would be an immense pecuniary benefit to any one who could raise a good free-blooming Perpetual Rose of that colour, which would have something of the form and good properties of the well-known John Hopper or Charles Lefebvre. How such a desirable variety is to be obtained is another question, but it has often occurred to me that the Austrian Brier is the right stock on which to work for the seed-parent, as we have nothing like it for purity and richness of colour, so that its progeny would most likely partake of that character to a considerable extent, while the habit would in a great measure depend on the kind that supplied the pollen.

In this matter Tea Roses should not be forgotten, neither should Maréchal Niel, Solfaterre, Cloth of Gold, and similar Roses. All flowers will take their own pollen before that of any other, and therefore, to make sure of effecting a cross, the anthers of the one intended to be operated upon should be removed before the pollen becomes ripe, or it is impossible to remove it without some falling off on to the stigmas, and thus defeating the object in view. These organs of the Rose are so hidden and overlaid by the petals that the best way is to remove a few of the most central, which operation will enable them to be the more readily got at and watched, so as to be taken in hand at the right moment. It is an easy matter with the aid of a pair of long, sharp-pointed scissors to remove the anthers, which should be done by clipping them out, taking care when doing so not to injure the pistils immediately contiguous to them. As soon as these are in a fit state to receive the foreign pollen, it should be introduced to them in the gentlest manner, either by using a camel's-hair brush, or by just touching the anthers containing it, when it will adhere and effect the desired purpose of fertilization. This done, all that is necessary is to preserve from rain and wind those that are operated on, which may readily be effected by tying

them to a stake and supporting a bell-glass, the top of a hand-light, or anything of that kind over them till the pod begins to swell and the petals have all fallen, when any protection they have had may at once be removed, so as to afford them the benefit of all the sun and air they can obtain in order to ripen the seed, which in ordinary seasons is fit for gathering by the end of October or middle of November, when it should be buried in sand for the winter.

The proper time for sowing the seed is from now to the end of March, so that any still on the plants may be gathered and treated at once, the first course to pursue with which is to rub it out of the husks, that it may be equally distributed over the ground. The best place for the seed-bed is a partially-shaded situation in the garden, as the seedlings succeed much better in this way than when sown in pots or pans and placed in pits or frames, where the small body of soil they contain is ever varying in condition as to the amount of moisture it holds, and uniformity in this respect is very essential with such seeds as those of the Rose, on account of the length of time they remain buried in the ground.

If the soil in which they are to be sown be not naturally light and sandy, it should be made so, and then pressed tolerably firm before sowing the seed, which should be scattered regularly over the surface and then patted gently in with the back of a spade, afterwards covering it over with sifted mould to the depth of about 1 in. Hand-lights are a great protection in warding off both birds and mice, either of which are very destructive just as the seeds begin to germinate; and as the glass draws a considerable amount of warmth if the tops be kept closed, the hand-lights help to bring the plants through much sooner than without their assistance. Air must, however, be admitted as soon as they make their appearance, as there is nothing so impatient of a close, confined atmosphere as the Rose, especially in the seedling state, when it is young and tender, and more subject to mildew than at any other time. Should this pest make its appearance, as it is almost sure to do, particularly if the weather set in dry and the plants lack water at the roots, sulphur must at once be applied, or it will get such a hold in a few days as to cripple their growth, if not to destroy them altogether. Unless the young plants should come up unusually thick in the seed-bed so as to crowd each other, it will be best to allow them to stand for the first summer unmolested, as their progress will be much more rapid than if they were pricked off, which operation necessarily involves a disturbance to their roots, besides the danger incurred of spoiling any young seedlings that have not at the time made their appearance through the soil, as many do not come up the first year. In order to hasten their blooming any that will afford buds should have them put in on healthy, strong stocks of either the Brier or Manetti, when the following summer an opinion may be formed as to their merits, and whether it is desirable or not to keep them for further trial. In case they are not budded, no pruning whatever should take place, but the tops left intact that they may become as strong as possible in a short time, and to assist them in doing this liberal and frequent applications of manure-water should be afforded all through the growing season.

Grafting Roses.

As regards grafting the Rose, although considered by many a difficult and uncertain mode of increase, it is one of the simplest and safest, as well as the most expeditious, if carried out under certain conditions, the principal and most necessary of which are suitable stocks on which to work them, and a close hotbed, frame, or propagating box, where they can be kept tilt a union is effected, which generally takes from three weeks to a month. The ready way in which the Manetti may be struck from cuttings put in at any time during the autumn, and the manner it adapts itself to all kinds of soil and situations, have long made it a favourite stock for the Rose, and as one-year-old plants of it may be purchased at a very cheap rate, any one can soon get up a stock fit either for forcing or planting out. If for the latter purpose, and the soil be stiff and clayey, it will be as well to make use of the Brier instead, roots of which may be obtained in tolerable abundance in most hedgerows; or failing these, any from such strong growing kinds of Rose, as Gloire de Dijon, climbing Devoniensis, the

Banksian, or those of a similar character, as they are sure to push strong shoots, and are well suited as stocks for Marchal Niel and others of that habit. To be successful at grafting, it is necessary to get the stocks, of whatever kind may be determined upon, considerably in advance of the scions to be placed on them, and this can be effected by heading them back and laying them in by the heels, where they can get a little moist heat. As soon as they have fairly started they will be in a fit state to be operated upon; and, in order to get the union as low down as possible, they should be cut back to within about 2 in. or so of the roots, in the case of the Manetti being used. These are best when of the size of a Cedar pencil, as then the stock and scion may be so fitted together as to bring the bark of both in immediate contact, which insures a more perfect and certain union, although they take very readily if they touch on one side only. In taking the scions, choice should be made of wood that is firm and ripe, which may be distinguished by its nut-brown colour and the small amount of pith it contains. To save time where many have to be grafted, the best way is to go over the stock of Roses, and take off as much wood of each kind as is likely to be wanted, tying up each variety separately with the names attached, when they can be carried to the potting-shed or other convenient place to be worked. Before doing this, each kind should be trimmed by having its spines taken off, and then cut up into lengths containing two or three buds each, the lowest of which should be situated at the extreme end, and towards this, from the other side of the wood, a sloping cut should be made, commencing at about 2 in. up and terminating at the bottom, much in the same fashion as when forming a quill pen. This completed, the stock should be cut at the side slantingly to receive the scion, both of which will then fit closely together, where they should be kept by being tied tightly with soft bass matting, laying each aside till the whole are complete, when they may either be potted singly in small pots, or packed closely in soil in the propagating box or frame, if space be an object, and be potted after they are united. Even in the limited amount of room afforded by a common hand-light, at least 100 may be accommodated, and if placed on a bed of leaves, or in a warm corner of the stove, it forms a very suitable receptacle for them. If the soil in which they are laid be in the requisite moist condition, it will not be necessary to give them any water, and, if possible, it is better to avoid doing so, as it is apt to get between the scion and stock, and prevent them uniting. It is essential to success that they should have a regular uniform temperature of from 75° to 80° with plenty of atmospheric moisture, and these conditions secured scarcely one in 100 will fail to grow, provided the wood is not soft and sappy, and the stocks are in proper condition. In order to maintain the heat at an equable rate, and prevent sun and light getting at them, they should be kept closely covered up for the first fortnight or so, or till such time as they start into growth, when light and air should be gradually admitted to impart strength and vigour to the young shoots. When firmly united, as may be seen by loosening one of the ties, they may be handled with safety for potting, but in doing this the ties should be left intact, otherwise many would be displaced during the operation, and if they be potted sufficiently low, as they should be, to cover the point of junction, the matting rots away gradually, and is gone long before any rapid swelling of the plant takes place, or any injury whatever is effected from its remaining. This kind of grafting may be carried on successfully at any time from November to the middle of March, after which the buds have started, and the growth on outdoor plants is generally too forward to proceed further. Those that have been forced, however, and have tolerably firm shoots may then be brought into use, and will succeed equally well with the others if treated much in the same way; except with those having foliage, they must not long be excluded from the light. A celebrated Rose grower near here grafts many thousands from wood of this kind, and by placing the worked plants in a close, moist temperature ranging between 80° and 90°, they unite in a fortnight, when they are removed to make way for others, and thus an immense stock is soon got up in a very small space, with scarcely a failure ever occurring. Compared with this, budding and most other modes of multiplying the

Rose are very slow and uncertain, and were it not for such a quick way of working them up, we should have to wait a long time before there would be sufficient of any new variety ready for distribution. Any one, therefore, who may be desirous of increasing his stock may readily do so at once, either from wood obtained from pot plants or those already established in beds or borders; but if the latter be used, it must be such as is not injured by severe frosts.

Roses on their own Roots.

Many, however, prefer Roses on their own roots, and in light, sandy soil, and for pot culture they certainly are the most suitable. Cuttings made from the young wood from pot plants any time after this root freely, although of course they take much longer to grow into size than such as are grafted, and have the roots and strength of the stock to help them forward. In propagating the Rose from cuttings, the firmest and ripest shoots should be chosen, the best of which are generally those that have bloomed, as they are always more solid and woody than any others. A piece, containing two buds with healthy green leaves attached, is quite long enough for forming the cutting, which should be inserted separately in very small pots in sandy soil, and placed where they can have strong bottom-heat, and be kept close till rooted. Plants propagated in this way now, and well cared for during the summer by keeping them potted on in good stiff, loamy soil as they require more room, and well watered with weak liquid manure, will make fine strong subjects for forcing next winter, and will be better for that purpose, if kept from flowering till that time, than others of greater age. With some kinds of Roses, such as the Moss and many others, layering may be resorted to with great advantage in getting up a stock, and this is an operation that can be carried out at any time by simply pegging down any of the lower side branches after giving them a slight twist, or tonguing them after the manner that Carnations are treated. If laid in and covered with sandy soil to the depth of 3 in. or so, they will root within the year, and may be severed any time during the winter, and used either for planting or potting.

S. J.

Verbenas Treated as Annuals (see p. 125).—I have been very successful with Verbenas treated in this way. I purchased seeds of the Auricula-eyed varieties, but instead of treating them as hardy annuals, I sowed the seeds in pans at the end of February, placed them on a mild hotbed, and when the seedlings were large enough to handle I pricked them off into other pans, and returned them to the hotbed until they were established; I then gradually hardened them off, planted them out in beds at the end of May, and I was never better pleased with any plants which I ever grew; their colours were rich and varied, and I do not know of any other flower that would have made so gay a bed as these Auricula-eyed Verbenas. I consider beds of mixed seedlings, kept well pegged down, to be preferable to beds of any one particular kind or colour.—JOHN CLARKE.

—“H. M.” should sow his Verbenas in pans or boxes in a hotbed; they cannot be grown in the open air with any certainty, as the seed will not vegetate freely without bottom-heat. I have grown them in this way for some time past, and get quite as many plants as I know what to do with, and quite equal to named varieties sent out by nurserymen; the plants are more healthy, and grow stronger than those raised from cuttings, and they bloom quite as freely. Of late years Verbenas have so altered in constitution that they are not so much grown as heretofore: raising them from seed will, however, doubtless give us a stronger race than we have had for some years past.—W. DIVERS, *Wierton*.

—If “H. M.” (see p. 125) will patiently wait for another three months, I should think he will see lots of seedlings coming up, provided the seeds have not been buried too deeply. Verberna seed may, as far as my experience goes, remain five years in the ground if several inches of soil cover it, and when hereafter the soil is turned over, and the seed brought to the surface, it will germinate and grow vigorously. If sown in shallow pans in a warm greenhouse, about half the seed sown will come up in from two to six weeks, and the other half will lie for an entire season before it germinates.—MAX LEICHTLIN, *Baden Baden*.

Iris reticulata.—Tempted by your favourable notice of this Iris I have purchased and bloomed successfully bulbs of it, but I have two faults to find with it:—1st. Its blooms are very short-lived, the standards generally becoming limp after three or four days, and

then falling prostrate. 2nd. The bulbs, instead of increasing, simply perish outright. Am I to blame for these shortcomings, or are they inherent in the plant? After blooming the plants in the greenhouse, I place them in a cold frame, and gradually diminish the supply of water until the foliage dies down in May, when I turn out the bulbs and plant them in the reserve garden. On searching for them in autumn I have hitherto been unable to find any portion of them left. Will any correspondent make suggestions as to the best means of preserving and increasing the bulbs?—H. M., *Bromsgrove*.

Lady Downes Grape.—Most Grape-growers will, I think consider this variety to be the latest keeper grown. There may be exceptional cases in which other late kinds may be preferred to it, but let Lady Downes be properly grown, and it will be found to keep at least a month longer in good condition than any other variety known to me. In the latest Vinery where it is grown here, no fire-heat is applied, except during the flowering period and a little in the daytime during the winter months, to expel damp in wet weather. It is usually quite ripe by the end of October, and in January or February the bunches are all cut and put into bottles of water, when the last of the crop is not over before the end of May; and one year I kept some bunches until the middle of July. Lady Downes has every characteristic of a late keeper, having strong stems to the berries, a thick skin, and although the flesh of the berry is rather firm for some to enjoy, their flavour is vinous and refreshing.—Wm. TILLERY, *Welbeck*.

Splitting in Fruits and Vegetables.—It is generally said that the splitting of Grapes, Apricots, Melons, and other fruits arises from a very wet soil accompanied by an atmosphere highly charged with moisture; my experience does not entirely accord with this theory, inasmuch as in some of the districts where there is the greatest amount of rainfall, splitting is not greater than in the driest parts of the country. From several experiments I have been convinced that splitting (as well as numerous other evils) is increased by extreme drought, which causes the fruit to become hard and the tissues to become woody; then the roots (which have for some time been struggling against adverse circumstances) get full supplies of moisture, plenty of sap is pumped up into the fruit, and to give vent to the sudden excess of growth thereby accruing, an outlet must be provided. I have seen the Josling's St. Albans Grape do well, and the "splitting" proportionately small when the Vine roots have been in a west border, which was shaded by trees, and heavily manured, and cropped with strong growing vegetables, while the inside of the house was kept full of plants up to the ripening period. I have submitted Melons and other fruits grown in pots to a similar test, but only found splitting when water was sparingly given at some period of growth, and an abundant supply administered at the time of ripening, but with plants from which the frames have been removed and left to drenching rains from the earlier stages of the fruit, splitting has been the exception. Last season a plot of fine Carrots grew to a good size, but stood many weeks in the soil (which had become almost as hard as a brick) without a drop of rain or any water applied to the roots (as there were no water stores), but at last the rain fell copiously, and on examining subsequently the bark-bound Carrots, they were found to be nearly all split.—M.T.

Campanula grandiflora.—Perhaps one of the most beautiful of all hardy plants is *Campanula grandiflora*, and its white variety (syn. *Platyodon*). This *Campanula* grows from 2 ft. to 3 ft. high, and bears in quantities up its long stems wide, deep blue flowers 3 in. across. It seeds freely, blooms in July and August, and is altogether one of the noblest of our border plants.—FRANK MILES.

Growing Rare Hardy Plants.—It would be convenient if your correspondents would be a little more precise. Will Mr. F. Miles say what he means by an underground tank (see p. 121)? Is it out of or in doors? Is it heated at all? How large (in all dimensions)? What built of? Is the soil a box, or medium, or dry? What thickness is the layer of sand? I delight in nothing so much as *Cypripediums*, *Cyclobothras*, *Calochortus*, &c., and am only tolerably successful. Any light thrown on the subject of their cultivation is very acceptable. Mr. G. F. Wilson told me he grew these plants in a somewhat similar way, but on a floating stage. I think Mr. Miles's plan may be more simple: will he give details?—A. R.

Preserving Maiden-hair Ferns in Water.—It is often a matter of annoyance in arranging cut flowers in glasses that the Maiden-hair Ferns do not last well. I find that the fronds stand well if a greater or less quantity of the pinnae be submerged in the water. Doubtless the slender rachis in this family of Ferns does not supply a sufficiency of moisture to the pinnae, but when some of these are also placed so as to absorb water, the lasting qualities of the fronds in a cut state are much enhanced. The plants used for cutting from are wintered in a temperature ranging generally from 45° to 50°, the plants being kept pretty dry all through the autumn and winter.—R. P. BAURNESTON, in "The Gardener."

Clematis indivisa (see p. 102).—Having seen this at Mr. Cripps', Taunbridge Wells, in great perfection, I purchased a plant of it, which I have grown very successfully in a pot, and now it is the admiration of all who have seen it.—J. ALLAN, *Ashurst Park, Kent*.

TREES AND SHRUBS.

OAK-GALLS.

During some seasons the Oaks in most parts of the country are disfigured and injured by the attacks of *Cynipides* or Gall-

Oak branch laden with galls.

flies. It is a curious fact that the same tree responds by the formation of a different form of gall according to the species of *Cynips* by which it is punctured. The most conspicuous disfigurement and the most exhausting to the tree is the large Oak-gall, which appears on the twigs; most other kinds in

1. Oak-gall (full size); 2. section; 3. larva; 4. female; and 5. male *Cynips*.

this country are on the leaves. The first woodcut represents a branchlet of a young Oak which the writer pulled in a Wigtownshire copse, and which bore in the short space of one linear foot no fewer than fifty-one Apples. Morbid conditions of animal or vegetable life which induce the attacks of parasites

undoubtedly exist, but the relation between them is not ascertained with any degree of certainty; and it would be difficult to say whether the unhealthy condition of a tree affected as the one from which this branch was taken was caused by, or was the cause of, the excessive outbreak of gall nuts. We may frequently see certain trees in a wood covered with galls, while the rest are almost or quite free from them. My experience is that young trees and copse are more liable to be attacked than mature trees, especially when the former are exposed to the influence of cold winds or grow on a damp subsoil. About the two latter conditions, however, I have not satisfied myself with sufficient evidence. SALMONICERS.

GARDEN FRAMES.

THE accompanying illustration shows a three-quarter, span-roofed frame for growing Cucumbers and Melons, and for storing plants, the invention of Messrs. Boulton & Paul, of Norwich; it is made so as to give greater height and more convenience than frames of that kind usually possess. The front is 11 in. high without the lights, 32 in. high at the ridge, and 22 in. high at the back. The front lights can be turned back on to the lights behind, and the back lights turned on to the front ones, thus affording free access to the plants inside. They are made of red deal and are glazed with 21-oz. sheet glass. The

illustration shows the lights to open with gearing, by which any of the lights can be lifted up when required without altering the others. The back and front gearing works separately.

CONFESSING THEIR ERRORS.

MR. R. GILBERT'S recent suggestion in THE GARDEN as to the desirability of recording errors has been anticipated in America. At a recent meeting of the Northern Illinois Horticultural Society, as reported in the "Prairie Farmer," a proposition was made and acted upon—"That we enter into a general confession of the errors that we have made in our horticultural life. Each one was requested to state but one error, and that to be a prominent one, for everybody knows if we should undertake to tell all that we have done amiss, we should not get away from Franklin for three months.—Mr. Minkler, of Osage, said that his greatest error was planting too many varieties of Apples in his orchard. He had at this time, he said, fifty varieties that were worthless. It was a serious mistake, and had entailed on him heavy pecuniary loss. He warned young orchardists to avoid this blunder.—Dr. Slade said his error was in planting dwarf Pear trees when he should have planted standards. He had not in ten years had any fruit from his dwarf trees.—Mr. Piper said his error was in digging great holes and filling in with stone, and planting his Pear trees on them. They died the second year.—Mr. Scott said that the blunder of his life horticulturally was in planting a Pear orchard at all. He planted with great care, and on the most laborious and improved plans, but it was labour lost, and he would have his neighbours avoid his error.—Mr. Cochrane said that about eight years ago he planted 100 Plum trees, and he hoped the Society would forgive him this time, and he would never do so any more.—Mr. Scofield had blundered in planting his Apple orchard on the wrong kind of soil.—Mr. Hansen, who exhibited fifty varieties of Apples on the occasion, got up and said, in lugubrious tones, that he confessed to the sin of having set in his orchard too many varieties of Apples; while it was some satisfaction to be able to show so many varieties of fruit, it was done at too great a cost. His experience, thus dearly bought, was of value to him and others in the future. But it is a mistake to set so many kinds of Apples; the profit is in the few varieties.—Dr. Pennington said he had made so many blunders that he did not know where to begin, nor could he tell which of his many errors was the greatest. He had made a great

mistake in ploughing his orchard late, followed as it was by a very dry season. He nearly lost his orchard by so doing, and it was four years or more before the trees recovered so as to show vigour and life again.—Mr. R. A. Whitney was requested to tell how it came about that he never made mistakes. He answered curtly, 'by keeping my mouth shut.' It was remarked that the 'old sinners' hang back, and would not talk freely."

American Apples.—We have these here for some three months every year, and I am curious to know in what latitude they are grown! I am an old tropical ranger both in the Old and New Continents; and, to my fancy, these superb Apples have a "low latitude flavour which our Apples of the British Isles cannot at all equal. They are styled generally Newtown Pippins, I think, and the great majority have an aroma reminding one of a Pine-apple. New York, whence they come, is 12° or 13° south of this (Dublin) latitude; but probably the fruit is grown further south than that. I observe that they arrive in casks without there being any other material whatever besides the Apples.—ASHLEY LA TOUCHE, *Monkstown*.

PRUNING PEAR TREES.

IN Mr. Fish's article on pruning Pear trees (see p. 151), he says—"Prune your Pears in November, and your trees will be in flower in February or March; prune them in February or March, and they may not be in bloom till April or May." Ascribing to the time of pruning such an influence as this over the time when the bloom expands will, I think, be something new to the generality of hardy fruit growers. I have always held that Apples and Pears are the most important fruits which we grow, and I have for the last thirty years given close attention to their cultivation, but the result of my practice is very far from being in accordance with the opinion which Mr. Fish expresses. I am always careful to consider whether or not any given practice will be followed by similar results in all parts of the country alike, for difference in soil and situation frequently exercise such a disturbing influence. What effect the time of pruning has over the time when the Pear blooms will expand in this part of the kingdom (the neighbourhood of London) I am not in a position to say, inasmuch as I have for many years contrived to have all pruning completed before the close of the year, except Peaches, Nectarines, and Apricots. For this I have two motives: first, I have always found that in gardening matters nothing is so conducive to success as keeping well up with the work. Secondly, I have a lively recollection of the aching fingers and toes, with severe cold, caused by standing out day after day pruning in hard weather during January and February, and I have no disposition to compel others to do that which I found very uncomfortable myself; but in different places where I have resided in the north of the kingdom, I know from actual experience that the time of blooming in Apples, Pears, Plums, Cherries, Gooseberries, and Currants, is neither accelerated nor retarded so much as a single week by the trees being either pruned in November as soon as the leaves are off, or left untouched till March. Further than this I have noticed that large standard orchard trees never subjected to any pruning at all, except occasionally a branch being cut out with the saw, just bloom as early, according to their kinds, as the same varieties do grown round the quarters in a kitchen garden, and kept closely pruned in every year before Christmas. This is a subject of considerable importance, and I, for one, should be glad if hardy fruit-growers in all parts of the country would favour us with the results of their observation as to what influence early or late pruning has upon these fruits.

T. BAINES.

VINES BLEEDING.

WHEN once Vines begin to bleed, there is no cure. I am glad to see that Mr. Smith follows up his advice (see p. 152), with the proper remedy, viz., starting the Vines into growth at once; late starting is probably the primitive cause of the bleeding. I would even go farther than Mr. Smith, and recommend a more than ordinary temperature till once the Vines break; it is the only way of stopping a wholesale loss of sap, the groundwork of the future crop. Five years ago I had the misfortune to deal with a range of Vineries in a similar plight, where the Vines had bled themselves to a state of sheer exhaustion. The remedy my predecessor took was as Mr. Smith recommends, burning the ends with a hot iron, throwing all doors and ventilators open, and laying the Vines as far as possible from the influence of heat and light, so as to retard growth. This was in the beginning of April. Our first act was to shut up the Vineries,

and apply heat and moisture, so as to encourage young growth as early as possible, a matter not difficult at that time of the year. We had a very light crop, indeed it is hardly fair to call it a crop at all, but our object was still in view, namely, to encourage liberal growth and a long season, giving plenty of heat and air during the autumn, the result of which was well-ripened wood as hard as bone. At pruning time we thinned well out, and the following year we had a crop of fruit which was quite unlooked for. Let me recommend this treatment to your correspondent who is seeking for advice, and if he have any suspicion of his border being badly drained or choked up, it ought to be seen to next autumn, or even now if the Vines be late ones—and in future bear in mind to start late Vines not later than the first week in February; better have fruit ripened under the influence of solar rays, than have badly-ripened fruit and wood, and a waste of fuel into the bargain.—W. HINDS, *Otterspool*.

Camellia Mathottiana.—Observing this *Camellia* noticed at p. 114, I am induced to state that having grown it for twenty years, it may be safely recommended as first-rate for planting in beds, but it is very difficult if not impossible to make it do well in a pot. The flowers, being very heavy, occasionally fall prematurely, but as they alight face upwards they are none the worse for the fall, and if furnished with zinc wire-stalks, and placed in vases amongst leaves, they produce an effect not to be surpassed. *C. Mathottiana* is a strong-growing variety, and bears any amount of cutting; many of the flowers are perfect in form, others are a little tufty in the centre; but both kinds are magnificent. The flowers of the white variety reflex too much. *Camellias* which grow too early and strong, and consequently do not set flower-buds, I have caused to flower abundantly the following season by pinching off the young shoots when 2 in. or 3 in. long; this may appear barbarous, but it is effectual.—C. E. ISHAM, *Lampport Hall, Northampton*.

Glazing Greenhouses.—"D.'s" suggestion (see p. 154) respecting glazing glass roofs by making a groove in each rafter and pushing the glass up from the bottom seems to be open to one grave objection. If a pane were broken at the top of the house, all the others down to the bottom would have to be removed in order to replace it, which would be rather troublesome if the rafters were 16 or 20 ft. long. Again, the idea of having the glass hollow down the middle like a pantile is a dreadfully expensive way of attaining his object, which can be accomplished without any expense whatever, except that attending a very slight difference as regards the cutting. If the glass be cut in the shape herewith shown, the rain collects at the points *aa*, and runs down the centre of the panes without touching putty or rafter—a circumstance which helps very much to keep them in a good state of preservation; all our newest houses are done in this manner, and although glazed in the old-fashioned way with putty above and below the glass, we are never troubled with drip.—C. E. PEARSON, *Chilwell, Notts*.

An Old Plant List.—Perhaps the following list of plants sent home nearly 200 years ago may interest some of your readers. Except two fine Tulip trees in the park and a border of *Gentianella*, I know of no trace left of this old importation, sent in the ship *Jeffreys*, from Sir Edmund Andros, to the then master of this house, who was one of the Commissioners of Plantations in the reign of William III. The list is dated 1693, and enumerates among other things Myrtles, fine-flowered Ivy, flowering trees (like *Sassafras*), Red-flowered Maples, Tulip trees, *Juniperus thurifera*, Honeysuckles, Red Cherry (bearing bunches like Currants), Bottle Gourds, Black Walnuts, *Smilax aspera*, *Arbor-vitæ*, *Violas*, *Solanum magnum inbrum virginianum*, *Gentian seeds*, Sweet Oak of Virginia, *Laurus flore tulipa* (tied with *Yucca*), large roots of *Yucca*, bushel of Peach stones, roots of *Drakena contrazorva*, Dwarf Chestnuts or "Chinkapins," *Cedrus baccifera*, Black Haws (tied with cotton), large roots of Fox Grapes, Woodbine Trumpet-flowers, *Clematis triflora*, roots of *Aristolochia minor*, and roots of *Dictamnus*.—B., *Gloucestershire*.

Pruning Lonicera fragrantissima.—"C. McD." (see p. 88) speaks of the advantage of skilful pruning in the case of this Honeysuckle. I have three plants of it, two trained against a wall, and one grown as a bush, and though they all look most healthy, yet the two against the wall flower but sparsely, and the bush (which has been planted three years) has never had a bloom on it yet. I should be very grateful if your correspondent could give me a few hints about pruning this plant. We had a heavy fall of snow last night (Feb. 25),

the ground being covered to a depth of fully 6 in., and to day I was favoured with the unwonted sight of a blue Hyacinth which has been in flower for two days in the open border peeping out of a bed of snow.—EDWARD A. WRIGHT, *Tickhill Castle, Bawtry, Yorkshire*.

DENDROBIUM HILLI.—Considering the effectiveness of this *Dendrobium*, it is surprising that it is not more frequently met with in collections of Orchids than it is. Several large plants of it are now in flower at Kew, some of them bearing from fifteen to twenty flower-spikes 12 in. or more in length, and thickly beset with creamy-yellow blossoms. Associated with other Orchids of different colours, this *Dendrobium* has a fine effect.—S.

The Royal Horticultural Society and Guinea Fellowships.—You have favoured me with space to advocate Guinea Fellowships when the Society is free; will you let me answer many inquiries as to what is best to be done now that the Society has offered Guinea Memberships without a vote? I would advise would-be Guinea Fellows to hold themselves in reserve for the present. They have agreed to be Guinea Fellows if accepted when the Society is free; the Society is not yet free, and Fellowships are not yet offered. I have sent in a proposal to the President which would, I think, fairly meet the present circumstances; immediately on receiving the Council's decision I will make it known.—GEORGE F. WILSON, *Heatherbank, Weybridge Heath*.

OBITUARY.

WITH great regret we have to announce the death of Mr. H. Ormson, the well-known horticultural builder, of Chelsea, which took place on the 20th inst. at Fern Bank, Ventnor. Mr. Ormson built many of the best garden structures in the country, and took pride in securing grace of design as well as the best materials for his work. He possessed much energy and manliness of character, and though ill health for some years has prevented him from paying much attention to his work, his loss will be felt by many. It is to be hoped that such an extensive and well-organized business will be continued by competent persons.

NOTES AND QUESTIONS—VARIOUS.

Vitality of Peas.—A gentleman living in this neighbourhood had presented to him last year by a friend three Peas, which had been found in the closed hand of a mummy in the pyramids of Egypt, and are supposed to have been there 1900 years. He sowed these Peas last spring at the usual time, and they all three germinated and grew, bore lilac blossoms, and fruited.—C. L. H., *Mooctesfield*.

Anemones at Christmas.—I want to get Anemones to flower at Christmas time; when should the seed be sown? I believe that a brilliant display may be had at Christmas by sowing seed at the proper time in the open air, growing the plants on and potting them up late in the autumn and placing them in cold frames.—A. Z.

Ripe Wood Strawberries.—Perfectly ripe fruits of the wild wood Strawberry have been sent us by Mr. Alfred Heath, of Ebury Street, Eaton Square, gathered, he informs us, a few days ago, from a hedge-row near Hadlow, in Kent.

Chrysanthemum ancistatum.—This is a remarkably curious succulent plant which assumes almost a ligneous character when grown out-of-doors. It is perfectly hardy, and looks not unlike delicate masses of green coral. What may be taken for leaves appear to be fleshy hooks (*ancia*), which being thickly placed on the dichotomous branches, give them a strange, yet pleasing appearance. It is invaluable as a rock plant, thriving luxuriantly even on the highest, and most exposed peaks, where scarcely a Lichen would live.—THOS. WILLIAMSTON, *Ormskirk*.

Gold-laced Polyanthes.—Purchasers of these should take care that the plants which they receive are what they are represented to be. Only a short time since I was recommended to apply in a certain quarter for named Polyanthes; I did so, and I received the following reply:—"I have just sent 100 to Mr. So-and-so, and 50 to Mr. So-and-so," naming two well-known florists, "and what you want shall be sent shortly." I instituted inquiries, and they resulted in my countermanning the order. All the growers of Gold-laced Polyanthes for exhibition purposes inform me that they are very scarce indeed, and it is disappointing to get seedlings palmed off as named varieties.—D.

Trees in London.—Two of the South London parishes have set an excellent example to local authorities by planting trees in the wider thoroughfares. The vestry of St. George the Martyr have just planted two rows of Planes along the entire length of the Borough Road and St. George's Circus, and that of St. Mary, Newington, yesterday commenced the planting of the Kennington Park Road with Planes and Chestnuts alternately. This season the New Kent Road is to be planted.

Swans and Water Weeds.—I had by some accident the American Water Weed (*Anacharis alinastrum*) introduced into my sheet of water, and it threatened to fill it in two years, but I put a pair of swans in, and in one season they cleared it out; and I know that the same happened at the Royal Botanic Gardens, Regent's Park; the swans got rid of the *Anacharis* in a very short time.—P. SQTAEZ, *Busmead Manor*.

The Wood Pavement in Piccadilly.—This in portions is being already lifted to be re-laid, London will be tired of wood pavements before many years go by.

Mistletoe.—Owing to want of space some correspondence on this and other subjects must be kept over till next week.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

NOTES OF THE WEEK.

CROCUS-GROWING IN LONDON.—For the last month I have had hundreds of Crocuses in flower on some leads at the back of my house. Many are planted in boxes in a light soil, and they flower admirably. Seven or eight large blooms to one bulb are not an uncommon number. I have found many flowers of good colour and fine texture measuring 2½ in. by 2 in. when the flower was partially open. The form of the flowers is good, and each lasts for several days; those I grow in pots usually last more than a fortnight, care being taken to remove them from the sitting-room to a cool-house at night. They are placed to flower upon a shelf protected by glass from the heavy rains and from smoke (of which latter I have more than my share), by a piece of Nottingham netting, which London flower-growers will find a most valuable method of protection. I have never seen anywhere finer Crocuses than those I have grown in this way after year. I believe it important to have the soil more light and porous than is necessary to grow well the same plant in the country. Cocoa-nut fibre refuse is upon the whole as useful as peat, and it is more easily procured in small quantities at a cheap rate (3d. or 4d. a bushel); one-third of the latter to two-thirds of ordinary mould with a little silver sand answers well. I keep my spring bulbs in a damp cellar, the temperature of which has been from 48° to 50° (a few degrees higher than is desirable) all this winter, until they are well forward and the flower-buds showing; they are then kept where there is very little light for five or six days and brought into a greenhouse, or placed upon the shelf before-mentioned to flower.—L. S. B.

ROTTEN ROW.—This has been the scene of a good deal of work during the winter, and its present condition is not without interest to persons employed in drive-making. Recently the deep bed of gravel with which it was covered has become a series of bogs disagreeable to riders. They originated as follows:—In the winter a thorough re-making of the "Row" was carried out, and the usual rubbish laid down to the depth of 18 in. This was thoroughly rolled with a steam roller till the surface was as hard and as impervious as cement. This would have been well enough if the water could have escaped to the side or could have escaped in any way. It was prevented, however, by the deep bed of soft gravel laid down over the hard-rolled rubbish to make the ride all that is desirable for horses. Where this deep bed of gravel is needed, it is necessary to have the underlayers quite pervious to water. There seems now no remedy that can be applied during the season except taking off the bed of gravel saturated to the consistence of liquid mortar, and replacing it with an inch or so of dry gravel laid on the hard-rolled surface.

TULIPA GREIGI IN LONDON.—Many of the best Tulips grow exceedingly well amid smoke, but *Tulipa Greigi* surpasses all that I have tried in its healthy appearance, perfection of form, uniform brightness of colour, and large size of the flower, each petal measuring 2½ in. by 1½ in. Three bulbs were planted in November, and one of them was out in flower in a cool greenhouse on February 16. Day after day the plant was brought into the warm sitting-room, where the flower opened and displayed the beautiful dark blotches at the base of each petal and sepal, the very regularly arranged short sepals, and triangular stigma. The flower has a delicate perfume, somewhat resembling that of Apricots. After having been well out for sixteen days, the petals are only now (March 4) just beginning to show signs of fading at the tip. This is one of the most satisfactory of the spring flowers I have yet grown. The leaves are spotted with brown and are arranged in very beautiful curves. At present the bulbs are expensive, but in a few years they will probably be obtainable at a moderate price.—L. S. B.

CULTURE OF IRIS RETICULATA.—In answer to "H. M." (see p. 181), I trust you will allow me to say a few words in favour of that gem of all spring flowers, the *Iris reticulata*. My experience is not only that the blooms are of long duration, but that the bulbs rapidly increase. At the present time I have flowers of it and its earlier though not so beautiful ally, *I. reticulata Krelagei*, that have been out for more than ten days, and some cut blooms that have been in water three days and are quite fresh now. As a proof of their rapid increase, bulbs that with me last year sent up one flower are now giving me three or four. I grow both under glass and in the open border without protection, in all kinds of soil; but the flowers

are finer, and last longer because the stem is stronger, in good meadow loam than in any other material. Those that have flowered in pots or jardiniers, I plunge in the open border in a sheltered spot, and they have always succeeded well. I only trust I may be as fortunate with *I. Histrio*, which has not bloomed with me yet.—ED. FARRER, JUN., *Petygards Hall, Swaffham, Norfolk.*

— Let "H. M." grow his plants of *Iris reticulata* in good sandy loam well drained, out-of-doors, and he will have no occasion to complain any more of losing his bulbs nor of lack of increase. I have two beds 8 ft. long and 4 ft. wide covered with blooms, the bulbs being the produce of some two dozen which I purchased four or five years ago.—A. R.

FAIRY ROSES.—Some thousands of these are now in flower in Mr. Maller's Nursery at Tottenham, where they form little pyramids, thickly studded with buds and small bright rose-coloured blossoms. They are grown in 48-sized pots, in good rich loam; and for small vases, window sills, and similar positions, plants grown and flowered as these are have few equals.

TREES IN WEST END PARKS.—A fine line of young Planes has been planted on the inner side of the drive in Hyde Park, and at distances to allow of a fair development of the trees. The long overcrowded trees by Piccadilly are being relieved by the removal of the Elms: this is as it should be, though the improvement has been too long deferred. The trees near the "Row" will soon require careful attention.

FORCED PEONIES.—Forced plants of the Moutan or tree Peony are now finely in bloom in the conservatory at Pine-apple Place, where their large bluish-coloured flowers have a fine effect. Plants of these for forcing are lifted from the open ground in autumn and potted, and placed in cool pits, where they are brought gradually on until the bloom buds become prominent, when a slightly warmer temperature is afforded them. Peonies will not submit to rapid forcing, but when brought into flower in February they are very valuable both in the form of plants and in a cut state for large vases. Outdoor plants will probably be useless for purposes of decoration this season if we have a continuance of severe frosts.—S. W.

A PRETTY GROUP.—We have had for some weeks past a charming little group in the stove that has pleased all who have seen it. It consisted of three kinds of plants only, viz., four good examples of that lovely Orchid, *Calanthe vestita*, as many of that no less interesting Fern, *Adiantum Farleyense*, and a few potsful of that useful winter-flowering plant, *Euphorbia jacquiniiflora*—each of the latter being from 16 in. to 20 in. high. Than these, few plants could form a better combination at this time of year, aye, or at any other season. If I were asked to add one other plant, it would be *Eranthemum pulchellum*, but with me it has just come in too late; nevertheless little plants of it would doubtless augment the beauty of the other three.—J. TAYLOR, *Hardwicke Grange.*

A NEW FLOWER MARKET IN PARIS.—To the already well-known flower markets of Paris, that, made since the war, against the new Hotel Dieu is an important addition. It is well worth the attention of all interested in city markets, from its simplicity of plan and fitness for the end in view. Beneath a young and healthy plantation of Paulownia trees are arranged neat, permanent stands with cast iron supports and zinc roofs; the paths and roads between are of asphalt and perfectly clean. In spring and summer, when the weather will permit, quantities of flowers are exposed in the uncovered spaces, and the roads and quays near are on market days covered with whole nurseries of plants, shrubs, and young trees. As the market is a large and very well supplied one, it need scarcely be said the scene is a pleasant one on market mornings. When it is over, the market place forms a desirable open space kept in perfect order, and as it is cooled in summer by the shade of the large leaves of the Paulownia, it is probably as useful to the surrounding inhabitants as a square would be.—V.

CYCLAMENS AS WINDOW PLANTS.—One of the finest *Cyclamens* which I have seen for long time is now growing in a farmer's window near this place. The window faces the south, and the room is one in daily use by the occupiers of the house. The plant in question has over forty large, fully-developed flowers on it of a beautiful pale rose colour, and when seen by lamplight, they have a striking effect, associated as they are with large finely-mottled foliage. The flowers are borne on stout footstalks, which are nearly all of one length, forming quite a mass of bloom. The plant is two years old from seed, and is growing in a 6-in. pot in a mixture of two parts sandy loam and one part each of peat and leaf-soil. It gets copious supplies of rain-water when required, and the leaves are occasionally sponged to prevent their pores from getting choked with dust. After it has done blooming, it is gradually allowed to rest; during the early

summer months it is placed out-of-doors in a shady situation, then re-potted, and brought indoors again as soon as it shows symptoms of growth.—H. J. C., *Grimston*.

PARMA VIOLETS IN PARIS.—Among the spring flowers in the Paris markets Parma or Neapolitan Violets are remarkable for being twice the size they are with us. They are sent to the markets in large pots almost covered with large flowers and with numerous unopened buds. They seem, however, to be placed in these pots but a short time. They are also sent to the markets in great quantities in a cut state. When well done, as they are here, they seem by far the best of all the Violets.—V.

MASDEVALLIA IGNEA.—A comparatively small plant of this Masdevallia, in one of the Orchid-houses in Messrs. Veitch's nursery at Chelsea, is now bearing from twenty to twenty-five flowers, the bright orange-scarlet of which is strikingly effective. If other varieties of Masdevallia could be induced to become as floriferous as this, they would doubtless be more extensively grown in private establishments than they now are.—S.

THE NEW STREET IN THE TUILERIES GARDENS.—The works for the construction of this have just begun, and in response to the wail of some newspapers about this so-called "violation" of the gardens, we may state that it is being made alongside the face of the palace, and that it will therefore "cut up" the garden in no serious degree. It will, in fact, merely replace one of those saharas of gravel which the designers of such gardens thought well to inflict upon us, and the area of which in the Tuileries gardens might be reduced with great advantage.—V.

SANTIFRAGA OPPOSITIFOLIA and its varieties are now in full flower in the York Nurseries, where special attention is paid to selecting and propagating such little gems from the best types. Of the variety of *S. oppositifolia* called *pyrenaica*, sometimes named *maxima*, I measured one of the flowers, and found it to be fully 1 in. in diameter. The petals individually, too, are broad, and overlap each other, rendering the flowers solid and circular. The colour is a soft, but bright and pleasing, shade of rose. Another good variety of *S. oppositifolia* is *splendens*, the flowers of which are almost crimson, and are produced in great abundance.—R. P.

RHODANTHE MANGLESII IN POTS.—This pretty Everlasting is not nearly so often grown in pots for conservatory or room decoration as it might be. Mr. Maller, of Tottenham, who devotes much time and space to its culture, grows it in this way in quantity for market. Seeds of it are sown in succession from early in February to the end of March in shallow wooden boxes, which are placed in gentle heat until the young plants make their appearance, when they are at once removed into a cool house, and gradually inured to sun and air. When large enough to handle, they are pricked off five or six together in a 6 in. pot in light, rich soil, and by the beginning of May they form handsome, well-flowered, bushy plants covered with blossoms. Three kinds are grown, viz., *R. maculata*, *alba*, and *Manglesii*. The sale of these Everlastings during the summer from this establishment alone varies from 10,000 to 15,000.—S.

PHALANOPSIS AT CLAPTON.—The Phalanopsis house in the Clapton Nursery is just now very attractive, the central stages and side benches being literally paved with baskets, each containing a healthy plant of Phalanopsis, nearly all of which are bearing at least one spike of rosy or white butterfly-like flowers; at a moderate calculation there are at least 1000 spikes, bearing in the aggregate some 5000 blossoms. The only other conspicuous occupant of the house is a specimen of the broad-lipped, golden *Oncidium varicosum*. A mean temperature of 60°, and abundance of air, light, and moisture are the main points observed by Mr. Low in the culture of these plants, the high state of luxuriance of which fully attests the soundness of the cultural conditions to which they are subjected. Among them we noticed some distinct and handsome forms of *P. amabilis* and *P. Schilleriana*, while a few of the specimens very closely resemble *P. Portei* or *P. Brymeriana* in habit; indeed, the last-named plant was a foundling obtained by Mr. Brymer in mistake, I believe, for *P. Schilleriana*.—B.

THE LATE MR. WILKINS' ORCHIDS.—The collection of Orchids formed at Leyton by the late Mr. F. G. Wilkins, was sold the other day at Stevens', and on the whole realised good prices, the more remarkable of which are as follows:—*O. longoglossum vexillarium*, 42 guineas; smaller plants of the same, 23 guineas; *O. Phalanopsis*, 29 guineas; *Laelia elegans Turneri*, 36 guineas; and other lots from 5 to 15 guineas, the total amount of the sale being between £1300 and £1400.

INTERNATIONAL POTATO SHOW.—The Potato Exhibition, which has hitherto taken place at the Alexandria Palace, will this year be held in the Royal Aquarium, Westminster, on the 3rd of October, and not in the gardens of the Royal Horticultural Society at South Kensington, as has been reported.

PINKS SUITABLE FOR FORCING.

THESE are most useful for furnishing flowers early in spring, and, indeed, in the case of some of the most precocious among them as early as Christmas. This section of Pinks is not as yet a very large one, but all the varieties belonging to it possess the merit of being most useful and well diversified both in character and colour. They consist of the old Anne Boleyn, yet a good, useful variety; the Paddington Pink, deep purple and white, and Rubens, dark purple, a variety of a dwarf and free habit. These have been in the possession of florists for many years, but they have been supplemented by improved varieties raised by Messrs. Clark, Lee, and Gibbons. Mr. Clark has raised several, but his productions are best represented by his two latest, namely, Lord Lyon and Derby Day. Lord Lyon is a very fine, free-growing and flowering variety; the flowers large, full, and of a deep, rosy-purple colour, and very distinct. Derby Day is a large, full flower, the ground colour deep pink, heavily laced with bright red, vigorous in growth, and of a free habit. Lee's coccinea is a bright scarlet—the colour being a great acquisition in forcing Pinks; the flowers are large and full, the habit dwarf and vigorous. This variety forces very well, and at the Royal Nursery, Slough, it can be seen in early spring in admirable condition. The plants scarcely get beyond 1 ft. in height, and they flower with great freedom. Lady Blanche Gibbons is a fine, pure white Pink, of good size, free habit, and it has the good property of not bursting, a great defect with some Pinks. It is valuable for bouquets, being very fragrant. Mr. Pettifer is a dwarf-growing, free-blooming Pink, the centre of the flowers of which is dark, broadly edged with white, and it is most useful for cutting from. He who would bloom forcing Pinks well in early spring, should have them well established in pots early in autumn. The size of pot must be regulated by that of the plant, but a 32-sized pot will be quite large enough for the strongest plants. It is not well to give them too much root-room; at Slough it will be found that the majority of the plants are in 48-sized pots. The soil used should be a good yellow loam, leaf-mould, manure, and a little sand. When the plants are potted early in autumn, they should be put in a cold frame, and kept there until well established. When the time comes for getting them into bloom, say in the early part of February, they should be put in quite a moderate temperature, and brought on gradually; for should they be placed in too great a heat, the plants will get drawn and produce weak flowers. They should be kept near the glass, and as they begin to throw up their flower-stems, a little weak manure-water should be given twice a week. Pinks of this kind are propagated by means of cuttings or pipings, much in the same way as those of ordinary florists' Pinks, but the operation should be performed much earlier in the season. The rule is to propagate as soon as pipings can be obtained, and it is obvious that the sooner this is done the stronger will be the plants by-and-by. Cuttings require a sandy soil, and should be struck on a gentle bottom-heat, when they soon emit roots; they should then be potted singly in small 60-sized pots, gradually hardened off, and finally planted out in the open ground for the summer in a well-prepared bed. They should be well looked after and kept growing, and when potting time has arrived, they may be lifted and potted for flowering in spring. During winter the plants are apt to become infested with green fly, which is easily destroyed by dipping the plants in Fowler's Gardeners' Insecticide, mixed as directed by the makers. All decaying leaves should be removed by means of a pair of scissors, as they sometimes communicate decay to the stems of the plants.

D.

Seedling Phloxes.—My dwarf Phloxes were raised from self-fertilized flowers of one I have as *P. frondosa* and *P. Nelsoni*, the latter a seedling raised many years ago by my late father from seed of *P. frondosa*, supposed to be naturally crossed by one then grown as *P. nivalis*, a kind I believe lost to the country for some years, but re-introduced from America by Messrs. E. G. Henderson & Son, and now sold by them as *P. subnata* *alba*. I saw it in bloom there last year, and at once recognized my old friend for which I had been looking many years, and had more than once had *P. Nelsoni* sent in substitution for it.—J. G. NELSON, *Aldborough Rectory, Norwich*.

THE FLOWER GARDEN.

HARDY FERNERIES.

WHILE flowers are indispensable for the ornamentation of a villa residence, a collection of hardy Ferns forms an equally important addition, and when properly and tastefully arranged they may be made to assume as natural an appearance as they do in a wild state; the rustic appearance, too, of a hardy Fernery forms an agreeable contrast to the more dressy portions of the grounds. It is difficult to lay down definite rules for the construction of a Fernery, so much depending upon the position which it is to occupy, and the space at command. In fixing on the site, the first thing to be aimed at should be a shady, secluded nook—not one that can be seen from the windows of the mansion or cottage, nor yet from the flower garden, but a part that is unexpectedly come upon when walking through the grounds. The situation should also be one that is sheltered from boisterous winds. Moisture, too, is essential to the well-being of hardy Ferns, but this cannot always be given in sufficient quantity to carry them safely through hot summers. In forming a Fernery, some object to tree roots, because they breed fungi, but I never found any inconvenience in that way from their use. Anything like straight lines must be avoided. If the space to be occupied be long rather than broad, it should be broken up here and there so as to form miniature dells, recesses, and projections, but all should have as rustic an appearance as possible. The plants in all cases should be allowed sufficient space in which to develop themselves. Where out-door Ferns have failed to do well, the Ferneries have generally been cramped for room. What is wanted is breadth and length, height being of secondary importance. If the Fernery be so arranged that it could be traversed by a narrow path from which the plants could be examined, all the better. The stones and roots employed should be placed in as natural a manner as possible, and yet they should possess a certain amount of artistic arrangement. Any one who has searched for Ferns in their native haunts cannot have failed to observe that they luxuriate in a light, sandy soil, and this must form, if possible, the main bulk of the Fernery. I have, however, many times used Cocoa-nut fibre mixed with turfy loam, and it has always appeared to answer admirably. For very delicate sorts a compost may be formed of peat, leaf-mould, and loam, with a sprinkling of silver sand to keep all open and porous, but the stronger sorts, as has been stated, will succeed best in loam without the addition of peat. When we use Cocoa-nut fibre we find that it retains a considerable amount of moisture without soddening. Fern roots being generally of a wiry nature will grow in almost any soil that is of ordinary texture, but it ought not to be heavy. Ferns dislike manure, both in a solid and liquid form. In arranging the plants I would not separate the evergreen from the deciduous kinds, but so dispose of them that when the foliage of the latter dies down in the beginning of winter, there would still remain plants enough to interest the cultivator. I would therefore plant plenty of sorts that would retain their verdure throughout the winter, such, for instance, as the *Blechnums*, *Scelopendriums*, *Polystichums*, and *Poly-podiums*. In planting, an error of too common occurrence must be avoided, viz., that of planting too deeply. Generally speaking, the crowns must be kept well above the soil, but they should be made firm, and the stronger-growing sorts should be planted first. Dwarf-growing varieties with fine

fronds should have the most sheltered nooks assigned to them. If water exist in the Fernery, a place must be afforded for the Royal Fern (*Osmanda regalis*). A list of hardy Ferns would perhaps be out of place, inasmuch as cultivators have their own particular favourites. I may, however, just add that a small Fernery may be constructed in any shady corner where flowering plants will not succeed, and if arranged according to good taste and judgment, it will always be a source of enjoyment to the cultivator. R.

EARLY WHITE SAXIFRAGE.

(*SAXIFRAGA BURSERIANA*).

ALL Saxifrages are beautiful, either as regards leafage or bloom, but none even of the conspicuous flowering kinds surpass this in vernal beauty. The plant is of dwarf, indeed, almost Moss-like habit, forming broad patches and spreading rapidly over the earthy interstices of warm, moist, sandstone rock-work if planted where it does not suffer from stagnant moisture. The accompanying engraving was made some twelve months ago from a plant in Mr. Ware's collection at Tottenham; it represents a small tuft in flower, but the blossoms are fully one-third larger than those shown in the sketch. They are borne singly on slender red stalks, which rise 2 in. or 3 in. above the general surface of the plant and are pure white, the

Saxifraga Burseriana.

margins of the overlapping petals being elegantly frilled or crisped as shown in the illustration. Interspersed among the fully expanded flowers the unopened buds (which are of a dullish crimson-brown colour) show themselves to excellent advantage, and enhance the pearly whiteness of the petals. Of all Alpine Saxifrages this merits the most attention, inasmuch as it is so markedly distinct from all its congeners, and its flowers are of sufficient size to render it a showy addition to spring-flowering, hardy plants. It may be successfully cultivated in a pan containing fibrous loam and sandstone, or coarse sand-

stone grit, a few nodules of sandstone being laid on the surface of the pan or pot among which the young growth and rootlets delight to creep in search of moisture. B.

SUMMER FLOWER GARDENING.

THE GARDEN, from the first number to the present one, has bestowed but faint praise upon the now fashionable style of summer flower garden embellishment, hardy or all the year round plants being, according to it, best for out-door decoration; but, whilst acquiescing in this, we cannot shut our eyes to the fact that summer flower gardening is still as popular as ever it was, but every year more or less improved—a result in no small degree due to the influence which THE GARDEN has had on such matters. I have a great affection for hardy plants, but at the same time I must confess that I have a liking for summer bedding in all its phases, and as the season for the preparation of plants for next summer's display is at hand, the present is a suitable time for a few notes on the subject. There are what may be termed four different styles of summer gardening, viz., the bright or colour massing and grouping, for which purpose *Pelargoniums*, *Lobelias*, and *Calceolarias* are mainly used; next the carpet, or formal dwarf-plant style, in which are mainly used such plants as *Alternantheras*, *Pyrethrum Golden Feather*, *Coleus*, &c.; next the quaint and neutral colour style, in which succulents of various types reign supreme; and, lastly, the sub-tropical style,

in which plants of noble growth and graceful foliage play the chief part. To my mind, a mixture of the four classes, skilfully worked out in conformity to the surrounding architecture, landscape scenery, and ground formation, is the beau ideal of flower gardening. For instance, what could be more appropriate, or more in character, for a geometrical terrace garden, with all its stone edgings, vases, and statuary, than the now fashionable carpet embroidery or succulent bedding? Granted that the system, in some of its aspects, is unnatural and should be discouraged, yet, be it remembered, that such gardens exist, and have been laid out and furnished at enormous cost with statuary, &c., and that their owners will not think of demolishing the same, but require them to be planted to the best advantage, and no better mode of doing so than that just mentioned has yet been put into practice; and till all stonework gardening is abolished, the formal style of planting must and will continue. Even the greatest admirer of natural gardening would, I think, admit that herbaceous and other hardy-flowering plants would be out of place where dressiness must be maintained at any cost, and flowers or bright foliage are looked for throughout the summer. It is, I know, possible to plant a formal garden in such a manner that the severest critic could not complain of excessive formality, for after all it is the abuse of carpet bedding that has brought it into disrepute in some quarters; and justly so, for when one sees bed after bed and arrangement after arrangement repeated without end, with no plants to break or relieve the monotony of flat surfaces, one has good reason to protest against the system. I have charge of a terrace garden—certainly not of the severest geometrical type—which has to be planted with the view of obtaining the best display from June to November, and therefore I am compelled to adopt the carpet bedding system; but I supplement it by dotting over the surface of necessarily formal arrangements plants of noble or graceful aspect, such as *Acacia lophantha*, *Dracæna indivisa*, *D. australis*, *Grevillea robusta*, *Yucca recurva*, and others. For formal succulent arrangements, "dot" plants of similar kinds are best suited, such as *Sempervivum arboreum*, *S. arboreum variegatum*, *S. phyllioides*, *Agave americana variegata*, and *Yucca gloriosa*. In such arrangements a judicious blending of beds of flowering plants, principally *Pelargoniums*, adds brightness to the whole, but on no account should succulents and flowers be planted in the same bed, or even fine-foliaged and flowering plants, save under exceptional circumstances. The colour-massing or grouping style of summer gardening is best adapted to a terrace or parterre that is well backed up or surrounded by evergreens, as these afford relief from the glare of brilliant colours, and at the same time set them off to advantage. In arranging such gardens the point to be kept in view beyond all others is so to dispose the colours that no uneven balance shall be discernible, and also to guard as much as possible against gaudiness by using a preponderance of quiet tints such as pink, white, and blue, colours of which the eye never tires. A few plants of noble aspect, distributed at regular distances apart over the entire garden, and especially in beds of glaring colours, will be found to enhance the beauty of the whole. *Retinosporas*, standard variegated *Euonymus*, *Thuja aurea*, and several varieties of *Yuccas*, are all suitable plants for this purpose. My view of sub-tropical gardening is that it is only suitable for positions where it can be associated with water, or for sheltered nooks and dells where the force of the wind is broken before it comes in contact with the plants, otherwise the first squall will so injure them as to make them objectionable for the remainder of the season. Where, however, such positions are not at command, the hardier class of noble or handsome-foliaged plants should be selected, many of which may be permanently planted, such as *Ailantus glandulosa*, *Rhus glabra*, *Phormium tenax*, *Arundo conspicua*, *Salisburia adiantifolia*, the *Yuccas*, and the hardy Palm (*Chamærops humilis*). Of half-hardy plants that will withstand wind, there are numbers, such as *Araucaria excelsa* and *A. Bidwilli*, *Acacia lophantha*, *Ficus elastica*, *Cycas revoluta*, *Dracæna indivisa*, *Aralia japonica*, and others. The *Abutilons*, *Ricinus*, *Solanums*, *Wigandias*, and *Ferdinandas* are soon torn with the wind; but nevertheless, they rank amongst the most effective of all plants where sheltered positions can be afforded them. In planting

sub-tropical plants, care should be taken to guard against the beds having what may be termed a "bunchy" appearance when fully furnished. To avoid this, plant thinly, and supplement by planting as undergrowth dwarfier plants, of which there are many suitable kinds, some of the best being *Gnaphalium lanatum*, *Cineraria maritima*, *Pyrethrum Golden Feather*, *Coleus* and *Iresine*. *Mignonette*, *Periwinkles*, and the stronger-growing *Sedums* and *Saxifrages* might also be used in this way.

W. W. H.

LILY BULBS.

"DUNEDIN" has not assisted us so much on this subject as at first sight he appears to have done. The theory of the "seed-bud" applies to one section of Lilies only, and is exactly what I had in view, and indeed recorded in my first paper in THE GARDEN (see p. 115) in these words:—"It may be safely said that no Lily bulb blooms twice from the same centre, and although most of the Japan Lilies seem to produce flower-stems from the same bulb (on closer examination we find that the flower-stalks spring from new buds formed within the old bulb every season), they are in fact new bulbs formed within the parent one every season, but remain attached to the same base, drawing in part substance from the surrounding scales," which I may here remark do not necessarily perish, since in many Lilies, and especially in *L. davuricum*, they become detached from the base of the old flower-stems, and form a whole colony of young bulbs. The term "seed-bud" used by "Dunedin" is an old one, and is calculated to mislead, inasmuch as the mode of reproduction which he mentions has nothing to do with the seed whatever, and is simply an axillary or scale-bud, popularly known by cultivators as an "offset." That these are truly axillary or leaf-buds is amply proved by their being produced on the leafy aboveground stems in the case of *L. bulbiferum*, and on the underground stems or stolons in that of *L. neilgherrense*. Of course physiologists are aware that even true seeds or "seed-buds" proper are marginal leaf-buds, but they are produced sexually, and not vegetatively and axillary, as is the case in the matter of Lily offsets. The constant reproductive process by axillary buds as described by your correspondent is just as applicable to all the bulbous plants with which I am acquainted as to Lilies. I should certainly date the origin of a Lily bulb from seed, and not from axillary or scale buds; and as to the question whether the Lily is an annual or perennial, that is self-apparent, inasmuch as a bulb of the old orange Lily once well planted will have increased some 50 per cent. in two or three years. There are one or two points about Lily bulbs on which I am by no means clear, and I trust that "Dunedin" may be able to render us some assistance. For example, I had always been led to believe that growth might take place without leaves, but that this was at the expense of substance, or cells previously stored up in the plant; we have, however, what appears to be trustworthy proof that Lilies not only become larger in the bulb, but also more weighty without the assistance of the leaves. More information on this point is desirable. Again, the three or four-fold jointing of the scales of some Lily bulbs yet awaits explanation. Again, there is an inherent vigour and hardihood in some Lilies from the same countries which others do not possess. Take the Japanese *L. speciosum*, for example: it always does well out-of-doors in our gardens, while *L. auratum* nearly as invariably dies during the second or third year, although the bulbs of both have been subjected to the same vicissitudes as regards importation, and been grown side by side in the same soil. These questions, and many others are well worth attention by those who take an interest in such matters, inasmuch as they are of great importance to Lily growers. Do Lilies raised from seed in this country grow and flower more constantly than imported bulbs, or do they, too, die out?—F. W. B.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Lily Bulbs.—"Dunedin" (see p. 175) has in *L. giganteum* an instance where a Lily bulb unmistakably dies after flowering and producing small side bulbs; in some of the North American Lilies, too, it can only be the young bulbs which flower.—G. F. WILSON, *Heatherbank, Weybridge Heath.*

Hardy Aquatic Plants.—I have a pool of water in my garden which in the present state is rather unsightly. Can you recommend me anything to plant that would grow in stagnant water?—SUSSENER. [The most ornamental of our native marsh plants might with advantage be naturalised in or around your pool; those best suited for your purpose would probably be *Iris pseudo-acorus*, *Eutomis umbellata*, white and yellow Water Lilies, Water Crowfoots, *Sagittaria sagittifolia* and its varieties; and to these might be added such exotic plants as *Talia ethiopia*, *Apocynon distachyon*, and *Gunnera scabra*, the last on the bank; if your climate be mild and genial, these will give satisfaction. It will be best to avoid planting too thickly at first, half-a-dozen good aquatic plants well planted will give greater pleasure than an intermingled mass without individuality.]

NEW PLANTS.

Turraea obtusifolia.—This pretty little shrub is a native of Southern Africa, its limits extending from Albany to Natal, apparently most common near the latter place. It is a plant which has often been collected; the living plants now at Kew, however, were raised from seeds sent by Mr. H. Hutton, of Graaefinet, in 1872, and flowered in 1876, after they had attained a height of from 4 ft.

Turraea obtusifolia.

to 6 ft. The above illustration presents a small flowering spray, and a coloured figure of it is given in the "Botanical Magazine," t. 6267. The flowers are pure white, and if durable, as we believe they are, they will be desirable for bouquet work. The plant grows well in a light, open, peaty compost, and a warm greenhouse temperature suits it best.

Draba Mawi is a native of Pancorbo in Old Castile, between Burgos and Miranda, where it was discovered by Mr. Maw in 1870, and introduced into his garden at Broseley and into the Royal Gardens

Draba Mawi.

at Kew. It flowered in the spring of 1873, and the fruit ripened for the first time in May, 1874. It is an excellent rock plant, of compact habit, bright green foliage, and red-brown buds, that are succeeded by crowded pearly flowers. It is figured in the "Botanical Magazine," t. 6186, where Dr. Hooker remarks, "It is not without hesitation that I propose as new a European species of the large and very variable genus *Draba*, but after a very careful examination and comparison I am unable to match the plant here figured with any known to me by specimen or description. It belongs to the section *Aizopsis*, and its nearest affinity is with the Spanish *D. cantabrica*, Willkomm (? *D. Dedeana*, Boiss. and Reut.), which differs in the yellow petals and elongate fruiting raceme. It also resembles very closely, in habit especially, the *Draba hispanica*, Boiss., a native of

Spain and Algeria, but differs conspicuously in the white flowers, broad petals, flat pod, and very short style. It has also the habit, form of pod and style, and many of the characters of the *D. Zahlbruckneri*, Host, of the Eastern Alps; but that has small flowers and glabrous pods."

Telfairia occidentalis.—A curious West African plant, belonging to the Cucumber family, and bearing five-lobed leaves on scandent stems. The flowers, which are white and purple-eyed, measure 2 in. across the limb, and are elegantly fringed. The angular fruits are 2 ft. in length, of a glaucous colour without, and rich orange yellow within, the purplish seeds being embedded in the yellow pulp in three rows. The seeds are as large as those of Almonds, and are said to be almost as good in flavour.—"Botanical Magazine," t. 6272.

Masdevallia attenuata.—This is a dwarf-growing, white-flowered species from Costa Rica. It is one of Messrs. Veitch's introductions, and flowered at Kew in December, 1874. It is pretty but not showy.—"Botanical Magazine," t. 6273.

Livistona australis.—A stately Palm from eastern temperate Australia, where it attains a height of 30 ft. In a small state it is a useful decorative fan Palm.—"Botanical Magazine," t. 6274.

Xanthisma texanum.—A Coreopsis-like hardy annual composite, bearing yellow flowers 2 in. across, of no particular beauty.—"Botanical Magazine," t. 6275.

Drimiopsis Kirki.—A strong-growing, bulbous plant from Zanzibar, bearing strap-shaped leaves 1 ft. or more long and nearly 2 in. wide, of a deep green colour with dark blotches. The simple scapes are clothed for about one-third of their length with nearly sessile, white flowers. It flowered at Kew in July, 1873; of no great beauty.—"Botanical Magazine," t. 6276.

Bauhinia petiolata.—A smooth-leaved shrub, introduced from New Granada by Mr. Linden, and which first flowered at Kew in 1862. Its white-petalled flowers are 3 in. in length and borne in short, racemose clusters at the extremities of the young growth. It is not likely to become popular as an ornamental plant.—"Botanical Magazine," t. 6277.

Oncidium cheiroporum.—A pretty little, winter-flowering Orchid from New Granada, now very popular in our gardens. It is of dwarf habit, having ovoid, one-leaved pseudo-bulbs, and slender, drooping panicles of odorless, yellow flowers. These panicles rarely exceed 1 ft. in length, the bright green foliage being still shorter.—"Botanical Magazine," t. 6278.

Cordia decandra.—A Chilean shrub first found by Macrae, when collector for the Royal Horticultural Society, in 1825. It is of easy culture, and bears bell-shaped, white flowers in clusters at the extremities of its slightly downy, leafy branches. It flowers during the spring months, and well deserves culture, as a warm greenhouse shrub.—"Botanical Magazine," t. 6279.

Tupistra macrostigma.—An Aspidistra-like plant, a native of the Khasia Mountains, bearing lance-shaped leaves on creeping rhizomes; nodding racemes of vivid purple, six-rayed, fleshy, flowers are produced by the young growths. May be useful as an evergreen fine-foliaged plant for pot culture, and decorative purposes.—"Botanical Magazine," t. 6280.

Cyananthus lobatus.—A perennial, herbaceous Bellflower, from the Sikkim Himalaya and Nepal, where it grows at an altitude of 10,000 ft. to 12,000 ft. The plant is of graceful habit, having pinnate foliage, the flowers being borne singly at the apices of the young growth. The flowers are 1 in. or more in diameter, and of a vivid Gentian-like blue colour, having a few whitish hairs in the throat of the bell-shaped corolla.—"Gartendora," t. 888.

Dracocephalum speciosum.—A bluish-purple Himalayan plant, much resembling the common white Dead Nettle in habit of growth. It was raised from Sikkim seeds by the Rev. Harpur Crewe, these seeds having been collected by H. J. Elwes, Esq. Not likely to be of any value as a decorative plant.—"Botanical Magazine," t. 6281.

Cypripedium Druryi.—A strong-growing Lady's Slipper, discovered in Mysore by Colonel H. Drury, in 1866, and exhibited by M. Linden, at Brussels, in April of last year. It has also flowered with Messrs. Veitch & Sons, and in the Kew collection. In habit it resembles *C. insigne*; the yellowish flowers are, however, smaller, the petals being very short, and the profuse spotting of *C. insigne* is here reduced to a dark purple band down the centre of each segment, and a few dots at the base of the petals. The scapes are shaggy like those of *C. villosum*. It is less ornamental than *C. insigne*.—"L'Illustration Horticole," pl. 265.

GARDENIAS PLANTED OUT.

As cut flowers for bridal and other bouquets, Gardenias are unsurpassed by any flower in cultivation, while for general indoor decoration the demand is invariably greater than the supply, both in private and public gardens, as their commercial value at all seasons will testify, and to meet the ever-increasing demand the system of planting out has of late come to be adopted with excellent results. I by no means would advise the total abolition of pot culture, as a portion of the stock might be advantageously so grown to meet special wants at particular or special occasions; but where great quantities of cut flowers are in request, a house or pit devoted to the culture of Gardenias planted out to grow into large bushes will be found a good investment. There is as much difference in the quantity of produce as there is between planted-out fruit trees and those grown in pots, while the amount of labour required shows a decided balance in favour of the abundant and more natural system of culture. Having a range of half-span hot-water pits erected here last spring for flower and early fruit forcing, with wide beds in front and narrow ones at back under the short lights, I resolved to devote the back beds of the hottest and the coolest divisions entirely to Gardenias, so as to prolong the season of flowering as much as possible. After putting in a good depth of potsherds for drainage, a layer of turf was placed over them, and I filled up with a compost of fibry turf, peat, charcoal, and thoroughly decayed mortar-rubbish in quite a rough state; in this good strong plants of *Gardenia florida* were planted, which produced a long succession of fine blooms, and made a most vigorous growth afterwards. It is now just a year since they were planted, and their general appearance is more like a plantation of hardy shrubs than one of Gardenias, and the branches bend under the weight of a load of pearly blooms and buds in various stages of development, the size of the blossoms being also in proportion to the size and substance of the foliage, and might easily be mistaken for white Camellias. Gardenias, like many other subjects, have suffered more from over-kindness and attention to orthodox rules as to temperature, soils, &c., than from lack of them. They enjoy a good brisk heat in the growing season, but are decidedly benefited by a cool regimen when the growth is perfected. And as to soil, they are such vigorous-rooting subjects that it must be a poor mixture indeed, if they will not grow in it; if compelled, however, to use but one description of soil, I should select turf from an old pasture stacked up long enough to kill the roots of the Grass. Peat is of such varied qualities that in many instances plants that are supposed to flourish best in it suffer from lack of nourishment, and when size and substance of produce are the objects, a liberal feeding ground for the roots is of the utmost importance. Soot-water acts both as a fertilizer and insect destroyer, and a top-dressing of good soil occasionally will be found very beneficial to the *Gardenia*, as it is an abundant and vigorous surface-rooting plant.

JAMES GROOM,

Henham.

The Double Poinsettia.—I have a plant of this, and should be glad to know the best way to grow and propagate it. It is now in a stove, where it has bloomed; it is well dried back, and has shed its leaves. Should it be kept in the stove until growth commences or not?—L. HANSON, *Halfpenny*. [Keep it comparatively dry until the end of April or beginning of May, then cut it down and strike the eyes singly in pots, as you would do Vine eyes, or allow the plant to break, and strike the young shoots.]

Two Good Wall Shrubs.—*Fremontia californica* is a fine plant for a south wall, bearing, as it does, large yellow flowers all the way up its growth. Another good wall plant, with a most deliciously scented flower, is *Chimonanthus fragrans*. It blooms in midwinter, is delightfully quaint, and perfectly hardy. I often wonder these two plants are not oftener met with than they are.—FRANK MILES, *Bingham*.

Sub-soiling with Dynamite.—An interesting experiment was, according to "Turf, Field, and Farm," recently tried with dynamite in Grape culture, which, from its complete success, is suggestive of still more wonderful uses for this explosive agent. In the case referred to, the dynamite was used in small proportions to loosen the earth and allow the admission of air and the free percolation of water to the roots of Vines. Holes were made in the soil about 10 ft. in depth, and at points where no roots of the Vines were likely to be injured. Cartridges of dynamite were introduced and exploded, and the result was that for the entire depth (10 ft.) the earth was made loose and friable; the ground, in short, was not only rendered in better condition than could have been effected by plough or harrow, but every phylloxera on the roots of the Vines was killed. The success attendant upon this experiment, though on a comparatively small scale, will undoubtedly lead to larger and more important undertakings.

HARDY FLOWERS IN LONDON GARDENS.

THE frosts which we experienced last week have played sad havoc with many flowers which have, owing to the exceptionally mild season which we have had, been blooming earlier than they naturally would have done in ordinary winters. Many, however, are still beautiful, and should a few fine days set in, the losses sustained by frost will soon be repaired. Crocuses and Snowdrops seem to be uninjured, and will be gay for a long time to come. The Scotch Crocus (*C. biflorus*) and its varieties appear to be the most continuous bloomers, inasmuch as they were the earliest this season, and they will in all probability be the latest. Some of the newer kinds of *Bulbocodium* are producing multitudes of showy flowers in Mr. Barr's grounds at Tooting, where also may be found in great beauty the soft, rosy-blossomed *Anemone coronaria*. The purple-flowered variety of *Iris reticulata* (*I. Krelagei*), is still in good condition, and established plants of *Anemone blanda*, growing on raised beds, are still in perfection, after having been in flower for nearly two months. A new and distinct Star of Bethlehem, sent from Asia Minor by Mr. Elwes, is also in blossom at Mr. Barr's; its flowers are produced in dense trusses close the ground, and are associated with long, thin, cord-like foliage; it has been in bloom ever since January last, and is still in tolerably good condition. The double and single red, blue, and white *Hepaticas* continue to be very showy, and the beds of *Scilla bifolia* are likewise still very attractive. At Messrs. Rollisson's *Aubrietia deltoidea grandiflora* is just opening its small lavender, Violet-like blooms, set on dense cushions of healthy green foliage. *Saxifraga oppositifolia pyrenaica*, too, is bearing numerous, bright pink blossoms: this is a very useful plant for forming edgings or for planting on rockwork; it flowers freely all through the spring, and forms a compact carpet of short and knotty stems the remainder of the year. *Ficaria grandiflora* and *F. ranunculoides*, in Mr. Parker's nursery at Tooting, are thickly set with large, glistening, golden-yellow blossoms; and in this nursery may also be found large plants of the window Candytuft (*Iberis semperflorens*), densely covered with pure white blossoms; associated with these may likewise be found a white-flowered variety of the great Strap-leaved Saxifrage (*S. ligulata alba*), throwing up large trusses of creamy-white flowers, which will be found valuable for cutting. The Spring Snowflake (*Leucojum vernum*) may also now be seen in great beauty in Parker's nursery, where its white, green-tipped Snowdrop-like blossoms are produced in great numbers. Here may also be found the Marsh Marigold (*Caltha palustris*), throwing up large, bright golden-yellow flowers from among abundance of green Ivy-like leaves. For planting near streams or ponds, or on piles of stones in damp situations, this is a very desirable plant, flowering, as it does, in such positions for several months during spring and early summer. The blue and white blossoms of Periwinkles now begin to sparkle on glossy-leaved stems that trail over dead roots or heaps of stones. The Satin-flower (*Sisyrinchium grandiflorum*) is also flowering freely in Mr. Ware's grounds at Tottenham, where many kinds of Narcissus are likewise at present exceedingly showy. *Triteleias* still continue to rank amongst the best of spring flowers; and Christmas Roses of different kinds are also in good condition.—In last week's GARDEN (see p. 165) *Dodecatheon Dens-canis* was inadvertently printed under one of the woodcuts instead of *Erythronium Dens-canis*.

Acanthus latifolius and mollis.—Seeds of these really beautiful *Acanthuses* sown now in gentle heat will furnish fine plants for sub-tropical gardens, and in addition to their outdoor summer attractions, they are well adapted for lifting for indoor decoration in winter. They will last in perfection indoors the whole winter in positions where more valuable but certainly not more effective plants would perish. The foliage of some that were not lifted last winter is still in good condition in open borders, but even if killed to the ground by severe frost, young leaves will again spring up. For amateurs who have but little glass these are invaluable either in or out-of-doors.—J. GROOM, *Henham*.

Laurustinuses.—These are very fine with us this season. I have one about 6 ft. high and 30 ft. in circumference entirely covered with bloom, presenting a magnificent sight; others are equally beautiful, though smaller.—J. ALLAN, *Ashurst Park, Kent*.

Grape Hyacinth
(*Muscari racemosum*).

Snowdrop (*Galanthus nivalis*)

Sky-blue Grape Hyacinth
(*Muscari botryoides*).

Marsh Marigold-leaved Pilewort
(*Ficaria verna*).

Spring Crocus (*C. vernus*).

Spring Star-flower
(*Triteleia uniflora*).

Garden Anemone
(*Anemone coronaria*).

Large-flowered Pansy
(*Viola tricolor* var.).

Heart-leaved Saxifrage
(*Saxifraga cordifolia*).

THE INDOOR GARDEN.

CALADIUMS AND THEIR CULTURE.

AMONG ornamental-foliaged stove plants, none are more beautiful or useful than Caladiums; indeed, so lovely are many of the newer varieties in the rich veining, brilliant colour, and grotesque markings of their leaves when fully brought out under good cultivation, that scarcely any artist could be found sufficiently skilful to depict them in all their glowing colours. Take *C. Belleynei* or *Prince Albert Edward*, the latter of which is a decided improvement on the former in many ways, and it will be admitted that nothing can surpass them in the delicacy and purity of the many shades of colour pervading the leaves, which, in the case of the latter are set off to greater advantage by the almost black massive stems on which they are supported. The great strength and stiffness of these give *Caladium Prince Albert Edward* a value beyond most of the others, in as much as it will flourish in a room, window, or greenhouse, and in many other positions where the weak, soft-stemmed kinds would at once give way and droop down. It is from this sturdy habit, coupled with its beauty and other good qualities, that I am inclined to place it first on my list, and to recommend it as one of the very best that can be grown for decorative purposes, and one that all should possess who have a stove or intermediate-house suitable for the growth of Caladiums. Next to this I would place *C. argyrites*: although this variety is in no way similar either in size, habit, or leaf-markings to the one just named, if I were only to grow two kinds my choice would fall on these, as they are more distinct than any other, and the latter is a perfect gem for table decoration, for which purpose nothing can be more suitable or better adapted in every way. The leaves of *C. argyrites*, as compared with the others, are of the most miniature description, and so is the habit and growth of the plant in every way, for when fully developed they rarely attain a height of more than 9 in., unless drawn up too much under shade, or subjected to an atmosphere so close and moist as to be unsuited to their well-being. There is something so chaste in the form and delicate marbling of the foliage of this that captivates all who see it, and those who are not so fortunate as to have made its acquaintance should lose no time in securing it or any other they may wish to have, now that the bulbs are dormant, in which condition they are much more portable and travel safer than at any other season. Another fine kind and a fit companion plant for *C. Prince Albert Edward* is *C. Dr. Lindley*, both of which associate well from their general habit and size so closely resembling each other, while they afford the most pleasing contrast, owing to the great dissimilarity of colour between them, a rich crimson predominating in the latter and white in the former, *Dr. Lindley* having the same kind of stiff *Alcacia*-like stems peculiar to these two varieties, which habit renders them so exceedingly valuable on account of their erect style of growth, a quality in which many others are sadly deficient. In selecting Caladiums, therefore, it is well to make choice of those that have the stiffest and stoutest foot-stalks as well as the handsomest leaves, an improvement in respect of which there has been considerable progress made within the last few years.

Among the newer kinds *C. Vesta* is remarkably handsome, having greenish-white veins that contrast strongly with the surrounding crimson colour, and this is banded again by the outer portion of the leaf being a lively green dotted with bright rose. *C. Princess Alexandra* is another distinct variety, having salmon-coloured leaves, with a conspicuous green mid-rib bordered with magenta-crimson, and the leaf margin bounded by a green belt with a most picturesque light pink chain running parallel through its centre. *C. Alfred Bleu* is likewise a very desirable kind, having rich green leaves, the centres of which are salmon-coloured, and the other portion dotted irregularly with pure white spots. Besides these there are many others almost equally good, but too numerous to particularize, all having some distinctive feature or peculiarity to commend them to the notice of lovers of this class of plants.

In addition to the stove varieties there is one of gigantic stature and size sufficiently hardy to stand in any greenhouse,

where, from its commanding aspect and the light green of its noble leaves, it courts admiration, and helps to break up that uniformity and sameness so common among the usual occupants of such structures. To use as single specimens in conservatories, halls, or corridors, during summer and autumn this *Caladium* (*C. esculentum*) has few equals, affording, as it does, a bold type of vegetation such as is required for furnishing places of that character. It is to be hoped, with this stock to work on, that some of our skilful hybridisers may ere long turn this variety to good account and endeavour to raise seedlings from it, which, if successful, would be of great benefit to the possessor, as they would be of far greater value than any of the stove kinds, on account of being more hardy and altogether of a bolder type. Unfortunately it is rather a shy bloomer, for although I have had huge plants for years, I have never yet had the pleasure of seeing any of them flower; it is a common occurrence, however, for the stove varieties to do so, which accounts for the great increase of new kinds that have been sent out of late. Besides the use made of this noble-leaved *Caladium* for indoor decorative purposes, it is very effective for forming groups, or beds, or for placing near the margins of lakes, ponds, water basins, or fountains, in either of which positions it produces a very striking effect. Where employed at all for any of these situations, the plants should be started at once by introducing them to any warm pit or house, where they can come slowly on, so as to form two or three good leaves by the end of May, at which time they may be turned out if previously hardened and allowed to stand till the end of October, when they should be dug up and laid in in any deep pit or frame for the winter. In pots they are very easy to grow, as all they require is free drainage, light, rich soil, and an abundant supply of water during the whole of the summer, otherwise their leaves will not obtain the proper size or assume that charming green tint for which they are so highly prized. To start the above varieties much more heat is required, and a fit place for them will be found in any *Cucumber* or *Melon* bed now at work; or, placing them on the hot-water pipes along the front wall of the stove. In the latter position they will require an occasional watering to prevent the soil from becoming too dry, but not so if plunged in any hotbed, as there the moist heat would keep them more uniform. It is the practice with some to shake out the bulbs and re-pot them in fresh soil before starting them, but I much prefer doing this afterwards, as there is much less risk of losing them, and it is an easy matter to make any increase that may be desired by dividing the bulbs with a sharp knife, an operation that should only be carried out after they have made roots and top growth, when the cut part soon heals over, which would not be the case were it performed before that time, as in all probability they would rot, especially if the soil become the least wet, or a very brisk heat were not kept up. In potting, the size of the pots must be regulated according to the strength or otherwise of the different varieties treated and the purposes for which they are required, as must likewise the number of bulbs, or separate pieces of the same, three of either of which of any of the strong-growing kinds will be amply sufficient to form grand specimens in 12-in. pots.

For general decorative purposes, however, pots of smaller size with only one bulb in each are far more useful, as they can then be dropped into vases to stand in window recesses or for table decoration, for either of which purposes few plants are better adapted. As they all require plenty of water during the summer, the pots should be well drained, and a free, open soil used, such as a mixture of tough fibry peat and loam, or leaf-soil, and the latter in about equal proportions, with just sufficient sharp sand to keep it open and porous. A little dry sand or charcoal dust placed against the cut part of any that have been divided will be found a great protection till they heal over, and until this takes place water should be given in the most sparing manner, as there is almost sufficient moisture in the bulbous roots to sustain them till they get well into leaf, at which time, unless in very large pots, they cannot well be kept too wet, if the heat be in proportion. In order to develop their rich leaf-markings to the fullest extent, they should be subjected to plenty of light, and only receive just sufficient shade to keep them from burning. Grown as they generally

are in a close, moist atmosphere under thick shade, their leaves are so thin and flimsy, and the foot-stalks so weak, that they are unable to remain erect without the aid of sticks and ties, the presence of which spoils half their beauty, independent of the weedy appearance such plants have compared with others grown with plenty of light and air as they should be. Caladiums are but slightly subject to insect pests, as the only kinds that affect them are green fly and red spider, the former of which attacks the young, unfolded leaves, but is easily dislodged by a slight fumigation of Tobacco, or by dipping their heads in Tobacco-water; and the spider is readily kept at bay by proper attention to syringing and never allowing the plants to suffer from want of water. The best way of treating Caladiums when high colour is aimed at, is to set them on inverted pots that they may have their heads clear above other plants and be up near the glass, where they will come stiff and strong and stand the air of a sitting-room when removed thither without showing the least signs of distress. Any ordinary pit will do for them during the summer if advantage be taken of sunny days to shut them up early in the afternoon and give them a good syringing at the same time. The autumn treatment consists in a gradual drying off till the leaves die away naturally, when the pots should be stored for the winter on the back shelves of a stove or some other similar position away from drip, where the temperature never gets below 55°.

S. J.

FORCING ROSES IN POTS.

ACCORDING to my experience—and I have forced Roses in nearly every kind of glass structure—there is no class of hardy-flowering shrubs more accommodating or more manageable under pot culture than Roses. If in good health and well established when introduced to the forcing-house, a crop of flowers may be looked upon as a certainty. The best kind of structure for early work is a low half-span house, with a pit filled with tree leaves in the centre, in which the pots should be about half plunged. The soft, genial atmosphere arising from the fermentation of the hotbed has a wonderful effect in increasing the vigour of the growth and the size and brilliancy of the flowers. In forcing anything, no matter what, there are certain principles bearing thereon which, although susceptible of modification in certain cases, yet cannot be altogether ignored if the permanent health of the plant be taken into consideration. For instance, it is not a good practice to introduce any plant to a high temperature all at once, nor yet to take it from a high temperature immediately to a low one. The right and true principle in forcing is to start with a very moderate temperature, and gradually increase it as growth progresses till the maximum is reached, and then to harden and mature the growth in like manner. In practice, however, this cannot always be carried out, for in many places the forcing house or pit is kept at one uniform temperature, whilst a constant stream of plants and shrubs grown for their flowers is passed through on their way to the conservatory or drawing-room. Of course neither the flowers nor yet the plants are so lasting; the former soon wither and die, and the latter, weakened and exhausted, soon succumb; therefore where a large and constant supply of flowers is required in winter, it will in the long run be more economical as well as altogether more satisfactory to have a house of intermediate temperature, and in the case of Roses this is more important in cooling them down when they leave the forcing-house than even upon their admission. To have really fine blooms the night temperature should at no time exceed 60°, with a rise of 10° in the day during sunshine. Where there is a pit of leaves in the forcing-house, and the floor and bare surfaces are occasionally damped, there will be no necessity for much syringing. I always think under such circumstances that if the syringe be very freely used, it seems to take the finish and gloss from the foliage, and there is always a lurking danger to be apprehended from hard or impure water, and Roses, even when grown only for cut blooms, should have a certain proportion of clean, healthy foliage associated with them. In a structure of the kind described, with a healthy, genial atmosphere, insects will not be very troublesome; but should green fly make its appearance, the moment its presence is known give

a couple of light fumigations of Tobacco or Tobacco-paper, with two or three days' interval between. Of course curled leaves should be watched for, and the little maggots that are usually coiled up therein destroyed. As regards varieties, all the most vigorous growers, no matter to what class they belong, may be successfully grown and forced in pots; but Teas and Hybrid Perpetuals are especially desirable to have in quantity. As a rule, all those kinds that do well in the open air will also succeed indoors, and to these may be added most of the Teas.

If fairly and liberally treated Roses may be grown in pots of the same size for many years, although of course where one has plenty of room it is best to allow and encourage a gradual development in size; or, if large specimens be desired, they can easily be shifted on into larger pots; and in time, with skilful training and care very handsome valuable plants may be formed. I have already said that Roses may be grown in the same sized pots for many years, and produce annually a crop of flowers, but it is necessary to re-pot annually, removing as much of the worn-out soil as possible, and using clean pots. I think there is no question that Roses, on their own roots, are best adapted for pot culture, but, whilst making this admission, I do not believe that raising them from cuttings is the most expeditious way of getting up strong plants. Grafting close to the collar of the seedling Brier, or, better still, on healthy roots, is a preferable mode, and will produce more vigorous plants in less time than if cuttings alone be used; and by simply burying the junction of the graft and scion when potting the plants, in the course of a year, or at most two, they will virtually be on their own roots. I lately removed some that were grafted on roots of the Brier two years ago, and each plant had formed numerous roots, above and altogether independent of the stock, and they would have sustained little or no check if the stock had been removed. I like the Brier as a stock for pot culture better than the Manetti. The latter has strong, stubborn, deep-striking roots, whilst the Brier is essentially a surface-rooting plant, producing a mass of fibrous growth. The strong contrast between the roots of the two plants would suggest the advantages to be gained by using the Brier for pot culture almost without any practical test. The indoor Rosery might be made a most interesting feature in any establishment, and one that could be enjoyed, even in the neighbourhood of towns where Rose culture in the open air is largely beset with difficulties, and even where open-air culture can be successfully carried out, there are usually more deaths among them annually than among a similar number in pots. Then, again, there is a never-failing source of interest in watching the unfolding of the leaves and buds in winter, and noting the numerous shades of colour in the rapidly expanding foliage of a collection of Roses, from glowing crimson to the brightest, freshest green. I do not think there is any other class of plants that shows so much variation in the ever-changing hues of their young growth, and this is especially noticeable early in the season under glass. With the necessary facilities for forcing, Roses may be had in bloom pretty well all the year round in any climate, but the flowers produced during the short, dark days of winter, have not the same bright colours, nor yet, to my mind, the same delightful fragrance that they have when the days lengthen in March. As regards soil, a good sound loam, adhesive rather than sandy, that has been laid in a ridge for six months to get mellow, mixed with about a third of its bulk of thoroughly decayed manure, will grow Roses in perfection; if it be intended to grow them continually in rather small-sized pots, a sprinkling of crushed bones might be added with advantage. There is one other matter in connection with forcing Roses to which I will just briefly refer, viz., the careless way in which the plants are too often treated when they have done flowering. All plants that have been forced—especially those forced early—should be moved to a cool-house or pit, so that they may gradually become hardened off, till they can be plunged in the open air. E. HOBDAV.

Amorphophallus Rivieri.—This is without doubt one of the most striking plants among tuberous-rooted Aroids. The leaf (for generally there is only one) is produced after the flower has died away, and frequently measures 4 ft. or more across.

PLATE LXIV.

THE SNOWDROPS.

Drawn by F. W. BURBIDGE.

THE SNOWDROP is the most welcome of all the flowers of the new year on account of its early appearance; and although one of the oldest and most abundant of all hardy bulbs, one never tires of its modest beauty whatever may be its surroundings, although Snowdrops never look better than when naturalised in large irregular masses amid tender herbage in old-fashioned orchards and paddocks, or on the margins of more kemptly-dressed lawns, or beside woodland walks, where their crowds of pearly pendants, set amid soft glaucous foliage, serve to usher in the Star Wind-flowers and golden Daffodils. Speaking of naturalization, the Snowdrop is one of the very few hardy bulbs which is sufficiently vigorous in constitution to propagate itself in a semi-wild state or on Grass. Perhaps this hardy vigor accounts for the fact that we are not dependent on the Dutch growers for Snowdrops, for nearly all our Snowdrops are grown in this country, and especially in Lincolnshire, where, in the vicinity of Spalding and Boston, many acres are devoted to the culture of Snowdrop and Narcissus bulbs of various kinds. In Nottinghamshire, too, near Bingham, considerable quantities of Snowdrops are grown for trade purposes. The cost of planting an acre of these bulbs in Lincolnshire is said to be at least £100; but, of course, on suitable, light, warm soils a proportionate return is obtainable. Almost any soil suits the Snowdrop, but deep, rich, well-drained gravelly-bottomed soils are most suitable, although in some parts of Nottinghamshire and Leicestershire we have seen them grow most luxuriantly on hedge-banks and in old orchards on the coldest and wettest of clay soils. There are four species of Snowdrop (*Galanthus*) in cultivation, all natives of temperate Europe and quite hardy in our gardens, where they may be used in an infinite variety of ways, not only in isolated masses on the Grass, but grouped on well-made rockeries or root-work, or in the wild garden, where they may be tastefully associated with *Anemone fulgens*, *A. coronaria*, *A. hortensis*, *A. blanda*, early purple and yellow kinds of *Crocus*, *Bulbocodium verum*, Winter *Aconites*, and *Iris* of various kinds, such as *I. reticulata*, *I. Histrio*, and *I. stylosa*, all of which bloom in January and February. As cut flowers, all the Snowdrops are most attractive, since they may either be grouped with sprays of Box or Ferns, or associated in bouquets and wreaths with Orchids, Rose buds, Forget-me-nots, and other choice cut flowers. To cull the flowers in the bud state is, however, essential in order to ensure their most perfect beauty, as they then bear carriage better and open fresher in water than when cut from the plants after they are fully expanded. Snowdrop buds so gathered will remain beautiful for ten days or even longer, while those cut after expansion on the plant will fade in about a week at the latest. As to the distinctive characters of the four Snowdrops now in cultivation, they are more apparent to the cultivator than to the botanist, seeing that their flower structure is almost precisely the same. *Galanthus nivalis* is recognised by its narrow leaves, dwarf habit, and small flowers; *G. plicatus* has very broad leaves, the margins of which are curiously turned down or deflected, and the flowers are larger than those of the first named; *G. Elwesi* is as dwarf or even more so than *G. nivalis*, but its leaves are half-an-inch or more in width, and the flowers are like those of *G. Imperati* but with more globose-shaped buds, and the inner petals have an oblong green blotch at their base as well as the usual double green blotch near the apices; *G. Imperati* is the most stately of the whole group, varying from 6 in. to 12 in. in height, the outer segments of the perianth being $\frac{3}{4}$ to 1 in. in length. As garden plants, these are distinct enough, but it appears to be a question whether all the Snowdrops are not forms of the same species differentiated by long continued growth under different climatic conditions.

Common Snowdrop (*Galanthus nivalis*).—This plant is the most northern and at the same time the smallest and only species with any pretensions to being a native of Britain. In Syme's English Botany the plant is figured and described as being found "in pastures, meadows, and orchards in many places in England and Scotland, perfectly naturalised and possibly native in some of the English stations, as at the base of the Herefordshire Beacon,

near Little Malvern, and near Wrexham, Denbigh." The authors of the "*Cybele Hibernica*" do not consider it thoroughly naturalised in Ireland. Of all species this is perhaps at present the most useful, being most abundant; and it deserves to be naturalised on Grass and in rocky or semi-wild parts of all gardens along with some Winter *Aconites*, *Anemones*, and other hardy flowers, not forgetting the common Daffodils, which flower so freely in the meadows of Herefordshire and other counties. A double-flowered form of this plant is very common in old gardens.

Crimean Snowdrop (*G. plicatus*).—This is generally considered a well-marked species, being easily distinguished from all the others by its broader and less glaucous leaves having deflected or plaited margins, whence its specific name has been derived. In Syme's "English Botany," it is said to be "a well-marked sub-species [of

Flower bud of *Galanthus Imperati* (natural size).

G. nivalis] from South-Eastern Europe and Asia Minor, larger in all its parts, distinguished by the leaves having revolute edges when young, and the apical lobes of the petal being less rounded." A figure of this plant evidently made from an ill-grown example is given at t. 2162 of the "Botanical Magazine."

Large Neapolitan Snowdrop (*G. Imperati*).—This is by far the largest-flowered species in cultivation and the most stately in

a. Flower bud and a single flower of *G. Imperati* (half natural size); b. Flowers of single and double forms of *G. nivalis* (natural size); c. Section of leaf of *G. Imperati*; d. section of leaf of *G. plicatus*.

habit, well-grown bulbs of it bearing nodding scapes from 10 in. to 12 in. in length. The leaves are twice as broad as those of the common Snowdrop, and of a more glaucous green colour. The flowers are of pearly whiteness like those of the last-named plant, and the bracts at the base of their pedicels are also frequently edged or margined with white. Another characteristic of this plant is the tendency its flowers have to be semi-double or malformed as shown

in our wood engraving, some of the petals springing from the base or sides of the ovary instead of from its apex in the normal manner. The outer segments of the flower are stout in texture and often 1 in. in length, the lips of the inner petals only bearing dark green, feathered blotches. When more plentiful this plant will be most valuable for massing on the margins of the lawn, or by woodland walks in warm positions, and apart from its beauty as seen nestling amid the Grass and other spring-tide vegetation, its flowers are very useful for bouquets and other floral decorations. This plant is a native of Italy, and has recently been introduced by Messrs. Back-

Elwes' Snowdrop (*Galanthus Elwesi*).

house, of York, and other nurserymen. Our figure of this plant was made in Mr. Barr's bulb ground at Tooting in February, 1875. The engraving of a flower-bud of *G. Imperati* (see p. 194) is from a sketch sent to us by Messrs. Backhouse & Son, and represents a large unexpanded flower (natural size); and to our mind it is thus far more beautiful than when open.

Elwes' Dwarf Snowdrop (*G. Elwesi*).—In general appearance this very nearly approaches the last-named plant, but it is much dwarfer in habit, rarely exceeding 6 in. in height. It is readily distinguished on close examination, however, each of the three minor petals having an oblong green blotch at its base in addition to the feathered blotches near their apices. A good figure of this plant

appeared in the "Botanical Magazine," t. 6166, together with the following description:—"This fine Snowdrop is very distinct from any previously described, though whether all these, namely, *G. nivalis*, L., of N. Europe, *G. plicatus*, M.B. (Tab. nest. 2162, a poor plate of a small specimen), of the Caucasian regions, and *G. Imperati*, Bert., of Italy (*G. plicatus*, Teore, not of M. Bieb.), should not, together with this, be regarded as geographical forms of one, may be a matter of opinion. *G. Elwesi* is nearest to *G. plicatus*, but differs in its basal sheath being more or less deeply notched or even divided on one side; in the leaves not being folded within the sheath, but twisted; in the larger flower and fruit; and in the form and colour of the inner perianth-segments, which in *G. plicatus* are not as in this constricted in the middle, and are merely notched, not bilobed at the tip, and are white with two confluent green spots confined to the top. Lastly, the anther-cells are shorter and broader in *G. Elwesi* than in the Kew specimen of *G. plicatus*. *G. Elwesi* is a native of the summits of Yamanlardagh Mountains, north of the Gulf of Smyrna, where it was discovered by M. Balansa in 1854, and whence dried specimens were distributed under the name of *G. plicatus*, being so named by M. J. Gay, of Paris. I am indebted to Mr. Elwes, of Miserdine House, Cirencester, an ardent lover of scientific horticulture, for pointing out its distinctive character from *G. plicatus*, and which Mr. Baker has confirmed. Mr. Elwes collected specimens on the mountains near Smyrna in 1874, and cultivated them in his garden at Miserdine, which bids fair soon to contain perhaps the largest and best private collection of well-named bulbous plants in the kingdom; it flowers in February, and is quite hardy." Our wood engraving is from a sketch made from a plant which flowered in Mr. Barr's collection in 1875.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Lawns and Walks.—The present winter has unmistakably exposed any defects that exist in the drainage; and where these are apparent means should immediately be taken to remedy them; and if the work be at once completed, the soil thoroughly well rammed down, and the turf carefully laid, the Grass will commence to grow directly, and the disarrangement in a few weeks will scarcely be perceptible. A wet lawn should never be tolerated, as after wet weather, even in summer, it is frequently for days unfit to walk upon with any degree of comfort. In draining a lawn the work should be so done as to insure the water quickly percolating from the surface down to the pipes; this is best effected by filling over them broken bricks, rubble, clinkers, ballast, or any similar open material to within 8 in. or 10 in. of the top. The whole surface should then be well swept, in order to remove all worm-casts, leaves, or broken twigs, and rolled so as to present a neat appearance. Those who take a pleasure in having their gardens orderly, usually each spring surface their walks with a thin sprinkling of fine gravel, independent of the general gravelling that is from time to time required; to effect this in a satisfactory manner, it is not necessary to pick up the old material to the same depth as when a considerable quantity of new gravel is laid on, still the surface should be loosened about 1 in. or so after a shower with an ordinary iron rake; but if the weather be dry, there is no necessity to wait, as the required softening of the old gravel can be easily done with a watering-pot. In the choice of material for this surface-dressing, it is necessary to study the nature of the gravel obtainable in any particular locality. Where the soil is of a loamy, adhesive character, with little or no sand intermixed, the gravel should not be so fine, that is, a larger-meshed sieve ought to be employed in riddling it, for although the very fine gravel looks well when smooth and set after being rolled in a moist state, yet, from its adhesive nature, directly it is wet it becomes sticky and disagreeable to the feet; no well-made gravel walk will ever become soft, no matter what amount of rain has fallen, except during a time of thaw after severe frost, when, as a matter of course, even the best gravel walks become loosened. In parts of the country where gravel is of a sticky, soft nature, it is best to pass it through a riddle with 1-in. or $\frac{3}{4}$ -in. mesh, afterwards using a fine sieve to screen out all the earthy portion, retaining nothing but the small stones; if this be sprinkled on the top so as to just cover the surface, and well rolled in whilst damp, it will make a walk clean, smooth, and pleasant to tread upon even in the wettest weather.

Kitchen Garden.—Make another sowing of Peas. Where suitable sticks are plentiful, tall kinds are the best to sow at this period of the year, as they bear longer than dwarf sorts, or such as are of medium height; where tall varieties are grown always give plenty of room; there should be not less than 5 ft. between the rows, as to crowd them is the reverse of any gain, for without sufficient air and light the pods never fill as they ought. Directly the earliest

sowings are staked, a line of Spinach should be sown between the rows; this will be ready for use and the ground cleared before the Peas are fit to gather, and it will in no way interfere with their growth. The main crop of Onions should be sown as soon as the land is sufficiently dry, but on no account if it be so wet as to adhere to either the tools or the feet, as should the seed be sown when the soil is at all sticky, subsequent dry weather will be sure to bake it so hard as to prevent it working kindly through the ensuing season. In pointing in the surface-dressing of manure previously recommended to be spread over the ground, do not let it be too deep, or the young plants will be too long in getting their roots into it. Many of the most successful North-country Onion-growers put the greater portion of the manure they use on the surface, allowing it to remain until it is well sweetened by the action of the air, sowing the seeds in it, and covering the whole with $\frac{1}{2}$ in. of soil from the alleys. With this, as with almost all other vegetables, I should recommend amateurs to adopt the system of growing in rows; I admit that it takes a considerable time longer in sowing than the broadcast plan, but it affords such great facilities for thinning the crops, for the use of the hoe in destroying weeds, and for keeping the surface stirred (by which the ground is aerated and made open for the descent of rains, and the loss of moisture by evaporation in dry weather is prevented), that the first trouble is amply compensated for by the succeeding results. The use of soot should not be omitted, especially in old gardens where the land is at all light, for in these the ravages of the Onion grub are most felt; the soot not only acts as a powerful manure, but the ground retains the smell through the season in a way that is so objectionable to the fly as to have a considerable influence in preventing it depositing its eggs on a crop where the land has been dressed with it. After the ground has been levelled, tread the whole quite solid; the lighter the land is naturally, the more solid it ought to be made; then mark out the rows 1 ft. apart and $\frac{1}{2}$ in. deep. After sowing, draw the soil over the seeds with the back of the rake; again tread the ground thoroughly, and finish by rolling. In dry districts where Broad Beans were sown about the beginning of the year, they will be now above the ground, and a second sowing should be made; this crop also likes heavy soil. Sow more Radishes, raking in the seed, it not being necessary now to cover it with litter. See that the litter is removed altogether from the second sowings as soon as up, for after this time the frost is not likely to be sufficiently severe to injure them. Sow a little Mustard and Cress every fortnight in well-manured ground; to have this young and tender, it is necessary to sow often. Lettuce should also be sown on the richest piece of ground available—a little of the Cabbage variety (Tom Thumb) as well as Cos—the former will be sooner fit for use and precede the erect-growing kinds. Rows for the latter should be 15 in. apart; the others will do a third less. In sowing, the best method is to drop the seeds half-a-dozen together in patches as required to be grown; afterwards thin them out to a single plant. If the weather be mild, a portion of those that have been wintered in frames should be planted out in a sunny, sheltered position, but do not risk the whole, as I have known the weather after this time to be so severe as to seriously affect them, especially after a winter like the present, when every kind of vegetation has been kept continuously soft and growing. Take them up carefully with a trowel so as to preserve the roots as far as possible from injury; give some water as soon as planted, and if the days be sunny or the nights cold, place a small flower-pot over each plant for a few days, but not pressed down so closely as to exclude the light. Now plant a row of the earliest Potatoes at the foot of a south wall on ground prepared as recommended a short time ago. In the case of this or any other crop planted in such a position, see that the wall coping slopes sufficiently to the back or opposite side so as to prevent drip. I have frequently seen instances wherein Potatoes, French Beans, or similar vegetables, when planted in such a situation, have either been destroyed or injured by the water dripping on them consequent upon the coping not being in the right position. A piece of ground should now be prepared and planted with Jerusalem Artichokes. Any out-of-the-way corner where little else will grow is often considered good enough for this crop, but it is a very great mistake to suppose that under such conditions the produce will be anything near equal in size or quantity to that which may be expected from a better position and treatment; not that it is necessary to choose for this Artichoke the best situation in the garden, yet it should have an open place away from the shading influence of trees, or from the impoverishment of the soil by their gross-feeding roots; the ground ought also to be well dug and moderately manured. Where a plantation of Horseradish has to be made, it is advisable to see to it at once; for this the ground should be well and deeply dug, and liberally manured. The thong-like portions of the roots similar to those planted in the case of Seakale are the best to employ, planting

them in a slanting direction; the longer they are the better, up to 10 in. or 15 in. if obtainable, as when grown the clean, straight piece of usable root will be in proportion to the length of the piece now planted. The cultivation of Horseradish on such a plan as the above is very much superior to the old system of planting the crowns, which, however deeply inserted in good soil, always results in the roots being shorter and more or less affected with dwarf, spur-like roots, which are useless. Horseradish likes a moderately free soil, and in situations where the land is naturally heavy, it will be much benefited by digging in 5 in. or 6 in. of road-grit, spent tan, or leaf-mould; or a mixture of the three together will be found to answer well.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

March 12.—Potting off spring-struck Petunias, Verbenas, Heliotropes, Aloysias, Salvia patens, and scarlet Lobelias. Shifting more French Beans into their fruiting pots; also potting Caladiums and placing them in Melon pit. Re-potting Ferns in loam, sand, and peat; also Nemophilas, and placing them in pits. Potting Cattleys. Getting shades on Dendrobium and Cattleya houses, and painting glass where required to keep hot sunshine out. Sowing Balsams, Celosias, Primulas, Victoria Stocks, Perillaz, Tagetes, Helichrysoms, Egg-plants, Nierembergias, and a good bed of Mignonette; also Spinach, a little Chervil, and main crops of Carrots and Parsnips, and also a little more Nonsuch Celery and Cress. Planting Potatoes, Shallots, Garlic, and Rhubarb, and filling all spare cases with Cauliflower plants; also planting a border with autumn-sown Tripoli Onions. Pricking off seedling Lobelias and Lettuce plants. Putting in cuttings of Vesuvius and Dr. Lindley Pelargoniums, and another forcing of Asparagus. Tying up more Lettuces under cases. Sticking early-sown Peas. Nailing Rose trees on wall. Digging Rose garden, manuring and digging land just cleared of Cabbage for Peas, and putting hills of soil in pit ready for planting out Cucumbers. Looking over Vines for thrips, washing Camellias, syringing East Indian Orchids (but not the Saccoboliums) every evening, getting rough manure together for Melons, and manuring Asparagus beds and covering them afterwards with sand. Gravelling kitchen garden walks, earthing up Potatoes in frames, and cutting away suckers from fruit trees.

March 13.—Potting stove plants; beginning to pot Dendrobiums in Moss, fibry peat, and small crocks; re-potting *Lælia anceps* Dawsoni. Planting *Schizostylis coccinea*, spring-sown Cucumbers, and Seakale plants for permanent beds, also Globe and Jerusalem Artichokes, and Ealm. Putting in cuttings of Fuchsias, scented-leaved Pelargoniums, and Centaureas. Preparing ground for Beetroot. Letting protections down over Apricot and Peach trees every night. Putting a layer of horse-droppings over Vine border. Manuring old Apple trees. Preparing more frames for Potatoes. Putting ashes over Peas. Giving Strawberry plants that are set some soot-water. Earthing up Peas. Pruning standard Roses. Cutting Laurels. Weeding walks. Keeping Vinery in which the Vines are in flower at 65 at night and 70 by day with fire-heat. Plants ready for house decoration—Crocuses, Narcissi, Hyacinths, Tulips, Lily of the Valley, Snowdrops, Forget-me-Nots, Primulas, Cyclamens, Sweet Brier, Lilacs, Rhododendrons, Cytisuses, Callas, and Mignonette.

March 14.—Potting Larkspurs, Schizanthus, Alyssums, and Melons. Taking up and re-planting young Wellingtonias; planting variegated Yews and Globe Artichokes. Dividing herbs, and re-planting in newly-made beds. Sowing a large bed of Chervil. Pricking off *Cineraria maritima* and Gaillardias. Digging flower borders; also land for seed beds. Putting in another batch of Asparagus roots for forcing. Putting *Maréchal Niel* Roses into Peach-house, placing Camellias in cool-house to keep back their blooms for Easter, and removing earliest Celery into cold frame. Thinning Peaches where too thick. Levelling verges in flower garden. Keeping Hamburgh-house in which the buds have just burst at 58° at night and 63° by day.

March 15.—Shifting some of the strongest of the *Calecolarias*. Potting off autumn-struck cuttings of Heliotrope; also cuttings of Colens. Shifting Cattleys, Lady's-slippers, and *Lælia purpurata* into larger pots. Sowing Auriculars and ornamental Grasses; also Leeks, Parsley, Radishes, and Rhubarb. Planting seedling Seakale, Rhubarb, and autumn-sown Onions. Washing and otherwise putting in good order some Camellias. Watering first Muscat-house border. Dividing old Violet roots ready for planting, and preparing land for them. Netting Radish beds out-of-doors. Staking Mignonette. Getting in loam for pot Vines. Earthing up Cucumbers. Heeing

between autumn-planted Cabbages and Onions. Putting Feverfew out-of-doors to harden ready for planting.

March 16.—Potting Balsams. Dividing and potting *Adiantum cuneatum* in 60-sized pots. Potting off Musk plants for balcony; also young *Fuchsias*, *Ageratum*, and *Alyssum*. Mossing *Cymbidium eburneum*. Blocking *Dendrobium formosum*. Sowing Laxton's Alpha, Champion of England, and Veitch's Perfection Peas, Broad Beans, and main crop of Onions. Planting Rhubarb roots for forcing. Pricking off Tomatoes and Egg-plants. Taking Hyacinths out of heat as fast as they open their flowers. Tying Vine shoots, and putting strings to last potted French Beans. Watering third Peach-house border; also Radishes in frames. Digging flower borders and beds; also land for more Carrots. Preparing ground for Asparagus new beds. Putting manure and leaf-soil in trenches for *Viola cornuta*. Wheeling in rubbish heap to garden. Inarching Vines. Panigating Strawberries and Roses in pots for green fly. Sticking Peas. Keeping Muscat-horse, which is coming into flower, at from 70° to 73° at night.

March 17.—Potting off *Petunia* cuttings. Shifting a few *Fuchsias* into 6-in. pots. Potting *Lælia anceps* in Moss and peat, and blocking *Dendrobium formosum*, *D. albo-sanguineum*, and putting fresh Moss to *D. chrysois* and *D. lasioglossum*. Sowing *Perilla nankinensis*, *Amarantus melancholicus*, *Humea*, *Celosia pyramidalis aurea*, and *Mignoneite* in heat; also Tomatoes, Walcheron and Early Loudon Canliflower; also sowing Ringwood Marrow and Bishop's Long-pod Peas, with Spinach between the rows. Planting more Seakale thongs; also putting out Canliflower plants between rows of Peas. Planting out *Carolina superba* and Frogmore Late Pine Strawberries. Pricking out two boxes of Lettuce plants. Putting in cuttings of *Scutellaria* and *Plumbago*. Putting Chicory in heat weekly. Getting Hollyhocks and *Dielytras* out-of-doors. Filling orchard-house with *Pelargoniums*. Sponging Vines for thrips. Taking up and laying in Parsnips.

GLAZING GREENHOUSES.

THE method proposed by "D." (see p. 154), and to which Mr. Pearson, of Chilwell, objects (on satisfactory grounds, as I think), I put in practice eight years ago, only instead of applying it to a greenhouse I covered a small outbuilding with Duchess slates (2 ft. by 1 ft.), pushing them up from the bottom, and securing them in their places with copper nails driven into the wood sideways, each slate resting at its lower end on the heads of the nails, and overlapping the slate beneath it. The upper part of each rafter was ploughed out on each side to the depth of nearly $\frac{1}{2}$ in., planed, and painted with two coats of red lead and two of Carson's Anti-corrosion Paint. Four slates make up the length of the rafters, and each slate has a piece of lath about 13 in. long, slipped in under it, to support it in the event of its cracking down the middle. The chief advantage of this arrangement is that you can so easily throw light into the building by the introduction of one or more panes of glass of the same dimensions as the slate; but I do not recommend the plan, for the saving in slate is not equal to the cost of paint and extra labour. Still less would I recommend its application to conservatories; for the latter Mr. Pearson's plan (see p. 184) is certainly the best. One of your correspondents has, I think, lately advised only bedding the glass in putty, dispensing with the usual application of it above: this is an old method. I have a house that was glazed in that way eight years ago, and a small portion of the glass still remains with only the bedding putty to attach it to the wood. If great attention be paid to keeping the margin of the glass well painted, where it joins the rafter, this method might be used with safety; but I found here and there a pane loose on one side, owing to a deficiency of paint on the outside of the junction, and I thought it better to have the whole of the top done over with putty in the usual way than to reset the loosened panes. There may be some little difficulty in getting glass in the form which Mr. Pearson recommends; perhaps he will be so good as to inform us where to get it cut in that way. But I much doubt if "D." will find any system answer better than the old-fashioned one which he denounces, if he will only cut his glass after the Chilwell pattern, and secure it with putty of the best quality, a matter perhaps of more importance than is usually attached to it. My Duchess slates are laid on a high-pitched roof, and if at any time rain gets into the grooves, it runs down and escapes outside; but in the case of an ordinary greenhouse, glazed on that plan, drip would not be prevented without the application of putty to the undersides of the glass in the grooves that support them. B. S.

THE FRUIT GARDEN.

SHOULD VINE BORDERS BE INSIDE OR OUTSIDE?

It has been asserted that the roots of Vines have an inherent tendency to travel towards the south; and this circumstance, if there be any truth in it, has been used as an argument in favour of planting the roots in an outside border, where they may have unrestricted liberty to grow in that direction. Vines are generally, although not always, grown in what are known as lean-to houses facing the south; and whether the roots are intended to occupy an inside or an outside border, they are placed contiguous to the front wall of the structure, while the rods are trained under the glass roof. Cases have also been reported in which suitable borders of soil have been duly prepared inside the structure, but into which the roots of the plants have refused to enter, or to extend themselves towards the back wall, and have been found years after having been planted tenaciously clinging to the front wall; and if not quite like Sterne's stalling, loudly asserting that they could not get out, were nevertheless endeavouring to do so, and disregarding the allurements which a bed of rich and suitably-prepared soil presented to them. That instances of this kind have occurred, I will not attempt to dispute; but I can, on the other hand, testify that such is by no means generally the case, and very many instances may be adduced to prove that the roots of Vines show no disinclination whatever to extend themselves towards the north. It must, however, be admitted that Vines whose roots are confined to the limits of an inside border are, however deep and rich such border may be, placed in circumstances somewhat similar to plants growing in pots. When Vines have attained to considerable age, the area of the structure may in many cases be insufficient for the continuous development of the roots; but as has been stated, this will only be found to be the case where the plants have attained to a very considerable age, and as young Vines are found to come very speedily into a bearing condition, unless in exceptional cases, it may not be advisable to retain them long after they have passed their best. In the case of Vines intended for very early forcing, most growers will be inclined to admit that it is desirable to have the roots inside the structure, where the soil containing them, being in immediate contact with the artificially heated atmosphere, cannot long remain quite cold, but must necessarily have its temperature more or less increased, and if not to the desired extent, it can readily be accelerated by the use of fermenting materials, such as tree leaves, &c., and this can be accomplished with greater certainty, and with much less labour and litter, than in cases where the roots of the Vines are contained in outside borders. It cannot be disputed that excellent early Grapes are yearly produced upon Vines whose roots are contained in outside borders, and much credit is due to those under whose management this is effected. But the easiest way of accomplishing any given object must be admitted to be the best, the results being equal, and few will be inclined to deny the difficulty which has to be encountered in keeping, during unfavourable weather, an equable temperature in outside Vine border by the use of fermenting materials, and where neatness is of importance, the use of fermenting material is doubtless objectionable.

All things taken into consideration, it must, I think, be admitted that inside borders are best suited for early Vineries. But for the production of late fruit, and where little if any artificial heat be given, the case is obviously altered, and in most instances preference may be given to outside borders, as by the time that the Vines are ready to start into growth the borders containing the roots from their southern aspect, and their generally elevated position, have had their temperature considerably increased by the action of the solar rays, so as to equal, if not exceed, in this respect borders placed inside the structure, and consequently to some extent shaded by the Vines trained under the roof as well as by the rafters. It is quite possible that even Vines bearing crops of late fruit might be greatly benefited by a judicious increase in the temperature of the soil containing their roots, applied at certain periods, when the strain upon the energies of the Vines might be considered to be most severe—say when the Vines are in bloom and about to set their fruit, and during

The Corsican Pine and Rabbits.—According to Mr. Pebbles, writing in the "Timber Trades Journal," the Corsican Pine is "practically rabbit-proof."

the finishing and colouring of the Grapes, usually a critical period. An increase in the temperature of the soil at certain times would, no doubt, be exceedingly beneficial to various other fruits and vegetables as well as to the Grape Vine; but the difficulty and expense consequent upon the adoption of any uniform system of supplying this desideratum, will always be likely to prevent earth-heat from becoming general. An approximation, however, to this is easily accomplished by the use of mulchings of various kinds in winter. Cultivators are all aware of the great advantage of bottom-heat in many cases, such as inducing the formation of roots in cuttings of various kinds, the restoration to health of sickly or exhausted plants, &c. The amount of bottom-heat which such plants as the Pine-apple will not only endure with impunity, but luxuriate in, is very remarkable; it must greatly exceed the temperature of the soil of the native habitat of the plant, and as one of the results of this, it is, we believe, admitted that finer fruit has been produced in British Pine stoves than has ever been seen in the tropical countries to which the plant is indigenous.

The application of bottom-heat to Vine borders through the medium of hot-water pipes does not appear to have as yet found favour among cultivators, probably on account of some of the few attempts which have been made to accomplish this desideratum having proved unsuccessful owing to some defect of arrangement. There does not, however, appear to be any insuperable objections to the use of hot-water pipes as a means of increasing the temperature of the soil of a Vine border, whether such border be inside or outside the structure. The danger of producing excessive dryness, which is, I believe, the principal objection to the system, can doubtless be successfully guarded against, so that I am inclined to think that the system may yet have a fairer trial than has as yet been accorded to it, and the result may probably be found to be a diminution of shanking and other ills to which the Grape Vine is so liable.

Culford, Bury St. Edmunds.

P. GRIEVE.

THE CLASSIFICATION OF MELONS.

MR. FISH has directed attention to a question of much importance, viz., the classification of Melons. The difficulty of such an arrangement is, however, almost if not quite impossible under existing circumstances, because every locality, or to put it plainer still, every cultivator seems to have a favourite variety of his own. I have never seen Little Heath Melon recommended as an early one; it may be an early frame Melon, but it certainly will not yield to hard forcing, that is, to stand a temperature of from 90° to 100° in a case of pressure for early fruit in May. I once tried it in an early house, and all seemed to go well till circumstances pressed us to hard forcing, when Little Heath showed symptoms the reverse of being comfortable in hot quarters, whilst it turned out well in a frame with only ordinary attention. We have far too many varieties of Melons or rather "names," and so long as the present system of raising new varieties is in force, and everyone is anxious to possess something new, I can hardly see the way to any thoroughly practical arrangement in the way of classification; for who can trust to getting any particular variety true to name? Where is Meredith's Hybrid Cashmere or Trentham Hybrid—both good Melons—but so far as I know, they and many other equally fine varieties have become extinct, or, to say the least, but very little of the original strain is left in what is now sold under their names. Our earliest Melon here is Malvern Hall, and I have tried scores of varieties. In the southern parts of the kingdom early Melon culture may be a very simple process, but in cloudy, sunless Lancashire to have Melons in May requires some skill and attention. I can confidently trust to having the acquiescence of all early growers when I state that to have ripe Melons in May in a climate like ours is one of the most difficult tasks that falls to the lot of cultivators. Strawberry forcing, Peach forcing, or any other that anyone likes to name, dwindles into insignificance compared with the difficulties which one has to surmount in ripening Melons any time from the middle to the end of May; it is true, however, that there may be exceptions, where modern houses with modern appliances are available; but I

am not treating of exceptional cases; I prefer to take the majority of instances as being the most useful for general information. We grow our earliest Melons in a span-roofed pit running east and west, where there is a deficiency of both top and bottom heat, especially the latter; the bed is 5 ft. wide, with one 4-in. hotwater pipe running up the middle; we have chambered off one-half of the bed so as to concentrate the heat, and fill the remaining half occasionally with hot fermenting material, which is no small assistance in keeping up the required temperature. We only plant the side of the house facing the south early, and after many efforts earlier in the season, I can recommend the 1st of February as being early enough to sow the seed, and in the earlier stages of growth a little "nursing" under a bell-glass, kept clean, will greatly facilitate growth. In this way I have cut fruit on the 20th of May, but it is oftener the last days of the month before I have ripe fruit, and last year it was the end of the first week in June. Through the kindness of Mr. Gilbert, of Burghley, I had Gilbert's Victory of Bath and Gilbert's Incomparable sent me last year, the latter a good early variety, producing very large leaves, and swelling off some excellent fruit. I have almost made up my mind that two varieties of Melon are quite enough to grow at one place; and if good varieties be required distinct, one variety only must be grown in the same house, otherwise the plants will be quite at the mercy of ants, bees, wasps, &c., to whose irrepresible intrusions we are indebted for many varieties we never bargain for. A commonly-accepted view with many people is that the seed of a good Melon must necessarily produce good fruit; this idea is a fallacy, the truth of which may be seen at a glance, because there is always the danger of unknown hybridization—the work of insects—and new varieties often revert to the original parentage in a way for which it is hard to account.

Otterspool.

W. HINDS.

FORCING AND ITS NECESSARY PREPARATIONS.

THE amount of success which may be expected to attend forcing will, in the majority of cases, be in proportion to the preparation which the subjects to be forced have received; for example, they for the most part require a season of rest, whereby their energies may be so concentrated as to enable them to undergo the ordeal to which they are to be subjected. This is of more importance than the most assiduous attention to temperature. It sometimes perplexes amateurs to know why such ordinary subjects of the forcing pit, as Lily of the Valley, Dutch bulbs, and culinary roots should, when started very early, be more difficult to get to respond to the influence of heat than an early Vinery or Peach-house; but in the latter case, starting readily into growth is only the natural result of an early season of rest, induced by gradually successive degrees. Forcing under such conditions is deprived of its destructive effects to such an extent that in many large establishments the earliest-forced houses will be found to equal, if not to excel, the latest or retarded ones, owing to the current year's wood being ripened under favourable conditions, which compensate in a great degree for the earliest stages of growth being carried on during the dullest and darkest days of the year. The same may be said of plants whose period of flowering is advanced by successive degrees, such as Camellias, Azaleas, and similar plants which make their growth early and flower early naturally in a very slightly increased temperature; and this is the only safe or satisfactory method, for if an unnaturally high temperature be needed to induce growth, it is a proof that want of preparation will be plainly visible in the produce. But in the case of hardy subjects, such as Lily of the Valley, bulbs, shrubs, or culinary roots, it is evident that their season of rest and thorough maturation so essential a point to precede forcing, must in a great measure depend on the season; and when the autumn is mild and vegetation is prolonged very late, great caution is necessary in starting such subjects, for if lifted and placed at once in heat, some kinds will refuse to grow at all, while in others but a very weak spindly growth will be the result. For the first stages of growth, there are few more favourable conditions than a pit filled with good Oak leaves, in which to plunge pots or boxes in order to induce root-action before the growth of leaves; the

moist atmosphere of such a structure will be generally sufficient with but slight assistance from hotwater pipes to start the plants fairly into growth, after which a gradually progressive temperature may be safely introduced. Where glass structures are limited, many such subjects may be advantageously forwarded in any underground or warm cellar, as after leaf-growth commences, and when light is absolutely necessary (except in cases when the produce is best blanched), the most critical stage will be passed, and they may be forwarded more or less rapidly, according to the urgency of demand, with good prospects of successful results.

JAMES GROOM.

Henham.

Lily and other Bulbs as Food.—Lily bulbs have long been used as food in Eastern Siberia, where they receive the general name of Saranà, the varieties most highly esteemed being *Lilium tenuifolium* and *L. kamschaticum*. *L. spectabile* is also employed as a nourishing article of food. These three plants are propagated with facility—*L. tenuifolium* exclusively by means of seeds, and the others by planting the scales of the old bulbs, every one of which forms a new bulb. This much we learn from a contribution by Dr.

HISTORY OF A FLOWER MISSION.

IN days when the efforts of the charitable are constantly met and checked by the unpleasant idea that well-meant benevolence is really doing harm, and tending to pauperise and injure the very people intended to be helped, it may be a pleasure to turn to something that, by no possibility, can injure anybody, for the strictest political economist could not think any one pauperised by a bunch of flowers. There is, indeed, another objection to Flower Missions sometimes put forward from an opposite point of view, when people say "The poor need the necessaries of life before its ornaments," and hint that the time and energy devoted to this object might be better spent in some other way. Doubtless, if people substitute Flower Missions for more direct forms of charity, this argument would have much force; but, practically, it is not so, and other charitable agencies are benefited by the sympathy between classes fostered by this unpretending form of expressing interest and goodwill. Besides, in this curious old world in which things will not arrange themselves according to our theories, we must often do what we can, rather than what we think it would be well to do; and therefore we shall be wise

An Algerian Oasis.

Fischer, printed in the "Flore des Serres" about twenty years ago. "There is at Kamschatka," he observes, "a Lily which comes near *L. canadense*, but which I name *L. avenaceum*, after the name which it bears in the country, and from the form of the scales of the bulb resembling large seeds of corn. In its native country this is also eaten like the ordinary Saranà, which is however preferred to it, the wild bulbs being obtainable in great abundance." A large-flowered *Erythronium Dens-canis* is also generally met with in Siberia, where it forms an excellent article of food; and in Russia, especially towards the south, the heaths and waste lands are covered with Tulips in the spring, and one variety, which perhaps does not necessarily differ from *T. suaveolens*, is eagerly sought for and eaten by the inhabitants.

—B.

An Algerian Oasis.—This is considered one of the most happily situated oases, and is well irrigated. Under the Palm trees smaller fruit trees are grown, and any other kind of garden cultivation practised by the inhabitants pursued. The inhabitants of Bouçada number as many as 7000, mostly Arabs, and the place, like many others which have played no political part, has no history, and nothing is known of its origin.

Gas-lime.—I intend dressing the kitchen garden here with gas-lime. Will any of your correspondents kindly inform me in what proportion it should be used per acre?—W. M.

not to neglect the smaller matters in running after the larger. We may not be able to do much to help our poorer neighbours, but it is always worth while to brighten the face of the dying man or the weary little child in its hospital bed with some bright blossom, reminding them of that fair creation of which they have seen so little. Then the Flower Mission can afford to take heed to a good many waifs and strays which are out of the way of other charities—the odd cases which do not fall into any definite class. It can venture to touch the shy and sensitive forms of poverty where the sufferers often have the most to bear and complain about it the least; for the flowers find their way not only to the hospital ward, but to the dull room of the struggling governess, the annuitant's home, where there is food and shelter doubtless, but little to spare for comfort; and to the big orphanage, which, at the best, but ill represents a child's natural home. Surely the trouble is not thrown away which brings some brightness and kindly thoughts to bear on all these varied cases. Many who do not exactly want the bare necessaries of life do sorely want some things to cheer them, and it is just this bit of cheeriness which the Flower Mission aims at giving. Any one who has ever read Hans Andersen's exquisite little story of the "Sick Child and the Pea Blossom," or that other better known one of the "Angel and the Flowers," will remember his pathetic treatment of the subject of flowers in illness. He wrote like the close observer

and true poet that he was; and Florence Nightingale spoke with the authority of experience when she assured us that the value of such things in illness is not half appreciated as it ought to be. Nor is other scientific testimony lacking to show how the flowers help forward the slow progress of convalescence. So we have good warrant for not allowing the Flower Mission to be thought merely a sentimental, superfluous affair; and now, perhaps, we may pass on to consider what it really is. The idea has spread so rapidly since it was first put into practice in 1872 or 1873, that many people are now acquainted with the practical working of a Flower Mission and the objects sought by its organizers; but as there are still many to whom the subject appears unfamiliar, some brief account may be interesting.

How to form a Flower Mission.

A Flower Mission, then, is merely an attempt to give the poor, and especially the sick poor, of our great towns, some enjoyment of the flowers of the country. The details may be, and are, modified to a great extent, but this is the fundamental idea on which everything else is built. The "Mission" (by the way that word is not a very happy one, for it suggests the idea of somebody preaching to the flowers as St. Francis preached to the birds, but having got the name, we must use it till somebody invents a better) may be started in various ways. It may be begun by one person, or several, or a whole committee, but whoever undertakes it must organize it properly, or the work will be a failure. An imaginary case will show the sort of arrangement necessary. Miss F. M. wishes to establish a Flower Mission in the district of B. somewhere in London. She has the time and energy, and has also the funds for the unavoidable expenses, for though Flower Missions do not cost much in proportion to the pleasure given, yet something will be spent, as will appear as we go farther on. Miss F. M. appeals to her friends in the country to help her with flowers, and gets promises of a tolerable supply. If she cannot do the work in her own house, the next step is to find a room, which is not always easy, as it must not be in an empty building, such as a schoolroom on holidays, for supplies will arrive irregularly, and somebody must receive them. It must not be too well furnished, for flowers and boxes and hamper do make a mess; and it must not be out of the way and difficult to find, nor must it have a high rent. However, we will suppose these difficulties overcome, and a suitable room secured, then, like every other general, Miss F. M. has to see both to her staff and her transport service. The staff will probably consist of a varying number of lady helpers, a messenger or two, and perhaps also a woman may be retained to clean up the room after the work is done. The "transport service," or means for getting the flowers taken to the sick folks, must vary according to circumstances. In many cases the institutions send to fetch them, sometimes the messenger of the Mission takes them, sometimes a lady undertakes to convey the supply to one or two places—but all this has to be arranged. Another important point in sending flowers to such large institutions as hospitals, &c., is to see that somebody can and will undertake the distribution of the nosegays, or else they may simply be wasted. In getting these matters into train, Miss F. M. begins to see how many places within reasonable reach will want supplies, and she finds there is one large general hospital, one workhouse infirmary, several special hospitals and convalescent homes, one large orphanage, two or three institutions for poor ladies, annuitants' homes, and so forth. Miss F. M. has also a list of people sick at their own homes, who must not be forgotten. She does not think it likely that she will have flowers enough for all these places, so she draws up a list of those to be supplied first, and the others come in afterwards. When all this is settled she chooses her day of the week, and can begin her operations. The necessaries for the work are few and simple; one or two tables, some shallow tins to hold water, some large baskets, a few chairs, scissors to cut the flowers, wool to tie the bunches up (ladies who have faded old wools may remember that the Flower Mission will be very glad of them, wool being much better than string), pens, ink, and paper, and a store of luggage labels for the empty cases. Miss F. M. has besides some little books for her addresses, accounts, lists of people,

all sorts of memoranda; and a towel and bit of soap for washing fingers when the work is done, complete the equipment.

The Mission at Work.

Having seen what the preliminaries of the undertaking are, we may now take a look at it when it is started and in full swing, and for this purpose we will pay Miss F. M. a visit one fine spring morning. An artist might take a sketch for a pretty picture, if he followed us into the bright room, where the sun is streaming through the open window. On the deal table in the middle of the room is a long tin dish, filled with bunches of Primroses and Violets—lovely to look at, delicious to smell—and the rest of the table is covered by a confused mass of exquisite spring flowers, interspersed with trails of Ivy, sprays of leaves, bits of Grass, and soft feathery Moss. A charming old lady sits at one end of the table, bringing order out of this chaos, with her slim, faded fingers deftly putting together the fresh young flowers, so as to set off their delicate beauty to the uttermost. As she finishes off knot after knot, a younger lady, with a brilliant streamer of scarlet wool hanging from her apron pocket, lifts them away to an improvised side table, while a couple of girls stand over the heap of flowers, tying them up as fast as their fingers can move. In the foreground of the scene, another girl kneels before a big hamper, just undone, and revels in the treasures within; "and all tied up," she says in a tone of immense satisfaction. Miss F. M. is sitting on an empty box, making calculations—so many packages have come, so many more may be expected, the supply of flowers is increasing, she can afford to be liberal to-day. At this moment, a light wooden box is brought in, this comes every week, so Miss F. M. marks it off on her list, pays a shilling for carriage, and enters that also, being a woman of method. This box is an excellent one of its kind, having two small trays inside, to keep the heavy flowers from the lighter ones, a strong lock (of which Miss F. M. keeps one key and the contributor the other), and on the lid are two slips of wood which hold the large card that bears the address of the Flower Mission on one face, and on the other, the address to take the box back to the country. One of the young lieutenants now unpacks it, lays a scrap of paper with "received with thanks" written on it inside, for some such kindly little acknowledgment is found to be an encouragement to the country helpers, then reverses the card, locks the box, and puts it with the empty cases, which the "parcel cart" will call for by-and-by. It may be mentioned here, how the railway porter who brought one such box to a Mission room every week, at last asked the ladies if they "could spare him a bunch of flowers for his wife," who, it was discovered, had been bedridden for years.

Fetching the Flowers.

But now a step sounds up the stairs, and the boy messenger gravely announces "the gentleman from the workhouse!" Enter the old pauper who fetches the weekly supply for the inmates of the infirmary, a bending old man with a gentle, refined face having a story in it, which would, however, take too long to tell. Fetching the flowers is a great pleasure to him, and he tells Miss F. M. as her fingers swiftly fill his big basket, how the people stop him in the street and ask if the flowers are for sale! The boy adds quaintly that "the children and the very dogs came running to see what he'd got." Miss F. M. smiles and nods, counting her bunches, as the girls pass them to her, and she tucks them in. So many sick being in those great, bare wards, almost any number would be welcome there—winter and spring! As the old man takes up his fragrant burden, a little girl in a red cloak comes in, her blue eyes opening wider at the sight of the flowers. She and a chubby companion have come from an orphanage for some flowers to brighten their schoolroom, and tell them something of what country beauty is. For though the sick people come first, the Flower Mission does not forget the children, who love the flowers so dearly, and these little things come walking some two miles to get their supply. Children and flowers go prettily together, so the baskets get as many small nosegays as they can hold, and the little feet patter away, while Miss F. M. marks down the number of bunches given in her book. One wishes the country children who gathered and tied

these little knots, could see the eager faces of the town young ones, to whom each flower is a treat; but the little senders have their reward, as many a clergyman's wife and school teacher can testify, in the unselfish spirit developed by the simple effort to give pleasure to other people. Now comes another arrival, a bright woman this time, come from an Invalid Ladies' Home, where a little cheering is very welcome. As she gets her flowers, a girl comes to the door, hesitating, shyly, as if not quite sure of her ground, till somebody asks her errand. "Please, m'm," she says diffidently, "I'm going to see my little brother in the — Hospital, and I thought maybe you'd spare me a bunch for him?" "To be sure;" and with a bright, sweet nosegay she goes on her long walk. More boxes come to be unpacked, and one of the girls opens a large hamper and stands aghast at the sight of the more than half dead flowers which it contains: from being badly packed, they have withered on the road, and are a dead loss. This is very grievous, but fortunately does not often happen. Miss F. M. thinks the "individuals," *i.e.* people living in their own houses, may get their flowers now, and this is more interesting, as she, or somebody, can tell something of the people to whom the flowers are going. "Mary Smith, dying of consumption, likes to have the flowers lie on her bed. Mrs. Jenkyns—if you please, Chrissie, find a very sweet one; she's blind, you know," and so it goes on. One request startles a stranger's ear a little. "Now one for the old poet." That sounds as if a story lay behind, and doubtless the old poet has his story, but all that transpires about him is that he is a bedridden old man close by, with a propensity for writing verses, and a great love for flowers. "They're better than five shillings," is the characteristic verdict of the old poet. At last, the basket is made up, and the messenger goes off with his flowers and list of addresses. Then the large hospital of St. Anne sends a capacious basket, into which the finished bouquets vanish rapidly, while the porter who carries it, confides to Miss F. M. that a fellow servant of his has a sick wife, who would be so pleased if he might take her a few flowers; and shortly after, a lady enters, asking if she can take a few to an out-of-the-way institution to which she is bound. One such flower-carrier was once met by a milk girl who looked longingly at the flowers, and then burst out, "Oh miss, do give me a Rose, just one." Of course, she got it, to remind her of the country home she looked back to, with passionate regret.

Odd Facts and Expenses.

Most of the flowers have come now, and the work slackens, and the helpers chat over their nosegays, seeing who can turn the odds and ends to the best account; and the pleasantest little talk springs out of the different supplies from different parts of the country, and odd bits of botanical lore come out, and the various names given to the same flowers get compared. Now, too, Miss F. M. has time to talk to her visitors and tell them anything they want to know, and she has plenty of interesting things to say about treats to ragged school children when flowers were plentiful, how rugged Poor Law officials were softened by the gentle influence, and the dreary work-house chapel was brightened at Christmas time by Holly berries; how one lady exerted herself to procure little "fishbowl" glasses to stand by each bed in one hospital, and little children in the country saved their pennies for this object. A whole bundle of letters is at hand, showing the wide-reaching links which the Flower Mission has created all over the country; one lady telling of the interest her school children take in getting the flowers; another saying how her maids help her to prepare her hamper and get through their work briskly on the "flower day;" and one and all uniting to call their efforts far more pleasure than trouble. Besides we now hear some of the odd little facts connected with the work, as the decided effect produced by the Epsom and Ascot weeks on the supplies, because when all the trains are altered, how can the flowers be delivered in time? And accordingly they come tumbling in at all sorts of hours, and make the manager's life a burden for that day. However, "nothing's lost that a friend gets;" and if the regular places come off badly for once, there are plenty of outsiders only delighted to have a turn, when the delayed boxes come too late for the regular distribution: a messenger goes to such places as firemen and policemen's barracks on

these occasions, to send for the flowers; and it is worth while to see the pleasure of these stalwart guardians of the public peace and order, at the little break in the formal routine of their lives and at "being remembered." Mission rooms, reading rooms, all sorts of stray places get a chance of the over-plus at such times, if they are only within reach. At last, the work is all done, the messenger who always comes for the remains, makes his appearance, and Miss F. M. sees everything finally arranged, empty hampers directed and ready to go back, everything in order, and goes home herself, probably pretty tired. Such is the outline of a Flower Mission day. The principal working expenses of such an organization as the one just sketched, are, the wages paid to messengers and assistants (though in all cases there will probably be a good deal of gratuitous service given, so this is a varying item), the rent of a room, and the carriage of parcels. This last item is the main one, and varies according to whether contributors prepay their packages or not. Many people will gladly take the trouble of sending a weekly box, who could not afford the weekly charge. Two of the great Railways (the Great Eastern and Great Western) generously carry the Flower Mission boxes half-price, which makes a great difference when contributions come by those lines. The empty cases cost 6d. or 8d. to return, so the weekly outlay under this head ranges from 8s. to 16s., supposing the Mission to receive an average dozen of packages. Sometimes country friends utilize an old tea chest, or box of that sort, which need not be returned, and so is a saving to the Mission. When one considers that from one little room go out sometimes 600 bunches and more in one day, the expenditure is not large in proportion to the pleasure bestowed; and stories of how great that pleasure is, would occupy only too much space.

Flowers and Scripture Texts.

One feature in many Flower Missions has been purposely left unnoticed till now, for it cannot be summarily disposed of, and to treat of it leads to somewhat delicate ground. The practice indicated is that of making the flowers a medium for bringing texts of Scripture to the notice of the sick people and others to whom they are sent. This is effected by having small holders or labels of cardboard attached to the bouquets, on which cardboard the texts are written, printed, or illuminated. Various devices are used to make them attractive, or to fasten them to the flowers, but the idea is the same. In some Missions, the number of bunches sent out is calculated by the number of these holders left when the full work is done; and in some it is arranged that the distributor of the flowers reads the text to each person when each nosegay is given. The advocates of this system urge that it is the duty of every Christian to endeavour to bring the Scriptures to bear on all who can be reached by them, and that the flowers give an opportunity of so doing, that the texts are valued and appreciated, and sometimes kept under the pillows of the sick, and it is hoped they make more impression, being, as it were, introduced by the flowers. The Bible Flower Mission, which has many branches in London, is entirely organized on this plan, and there are others in the country and also in Edinburgh. On the other hand, those who keep to the simpler plan of only sending flowers, say that the text system, in practice, comes to the indiscriminate sending of any text to any person whether suitable or not, that it is very difficult to keep any control over the choice of verses, and prevent such mistakes as that of the worthy person who, as it is said, selected "Thou shalt not steal" as an appropriate text to go to a sick child! Again, that such use of detached bits of Scripture is apt to be anything but edifying, unless managed with a discrimination and care almost impossible in the Flower Mission work, and that it ends in treating the Bible like a sort of charm of which any and every bit is equally useful. Another disadvantage incident to this plan is, that it makes the Flower Mission less of a thing in which people of all shades of religious belief can join, and in these days we cannot afford to lose points of union. Further, it is argued that the people to whom most of the flowers go, are in institutions where they have full opportunities for hearing and reading the Bible, and that little is gained by, as it were, pushing it down their throats. The flowers bring their own message, and at the lowest, they tell of the interest

and sympathy of other human beings, although far away and unseen, and this is really felt to a great degree. "It's so nice of people in the country to remember us," said one old sick woman speaking the feeling of many. But the flowers do more than this, they take the people back to their childish days of innocence, only comparative innocence perhaps, but still a softening memory to most, and dull eyes will brighten, and hard faces grow gentle, as man or woman glances back to "when I was a young thing at home and got primroses in the ditches;" while the glad beauty of the flowers speaks home of the power and love of their Creator "who hath made all things well." And so many, including some well acquainted with the practical working of the other system, think that the flowers are both text and sermon in themselves, and that we may leave burning crimson Rose, and heaven blue Forget-me-not, and snow-white Lily to be signs of love, hopes and purity more impressive than any words. It may be considered an exaggerated scrupulousness, but to many minds it does not seem quite the right thing to be preparing religious instruction among the bustle, the inevitable talking, the going and coming of such work as that described above; and it is a positive pain to see sacred words thus misapplied, to pass through careless hands and often be tossed away as waste paper. Another apparently slight, but real objection, is the scarcity of people who can write distinctly enough for uneducated or failing eyes. If, on the other hand, the texts be printed, the expense would be a difficulty, and the personal interest in the work of preparing them, which is now much dwelt on, would, in a great measure, disappear. If the texts be admitted as part of the Flower Mission work, it does seem necessary that some person of judgment and discretion should be told off strictly to supervise the texts received; and also that special arrangements should be made at the place supplied as to the distribution, that it should not all go by chance. It must be remembered here, that not every institution has the means of making such arrangement without entailing more work on those already fully occupied, for the sake of a merely possible benefit. If this side of the matter have been more fully dwelt on than the other, it is because it seems to have been ignored in some publications on the subject. Probably experience will decide which way works best, for we are but young in Flower Missions yet. The first was started in Hull in 1873 by one whose time might have been supposed to be fully occupied, but who found it possible to organize this work which has spread so rapidly. Miss Stanley began it the same year in London, where there are now many branches and depôts. It has been found impracticable to obtain a full list of all the London Flower Missions, but the addresses of as many as have been heard of, from various points, are collected into a list at the end of this paper for the convenience of any wishing to assist in their work.

Hints to Intending Contributors of Flowers.

And now we would make appeal to those who revel in flowers all the year round, whose gardens and greenhouses glow with beauty, to remember their fellow creatures, to whom even a green leaf is a rarity and a treat. It is not money that is asked for, it is only the excess and superfluity, fading away unheeded, which would be so prized; we want to gather up the fragments of the country's feast. It is not, however, only with the rich that the Flower Mission pleads, it is also with everyone who has access to the treasures of wood and field, for the wild flowers are just as attractive if they only come in pretty good condition; and many a charming hamper of such comes to the Flower Mission, whose contents have been gathered and tied up by children. So much pleasure might be given if those who could help in this matter would turn their attention to it and assist in riveting a bond betwixt town and country. They would find it a blessing "both to him that gives and him that takes," for we hear on all sides how the interest and love for the flowers are awakened in country districts by finding out how the half-despised "common things" are valued far away. Is not, also, something gained in quickened and widened sympathies, when people begin to realise the trials and privations of those they do not see, and from realising, go on to trying to help? Is not this the complaint of country dis-

tricts, that their ideas and interests are so limited? Then surely that must be an education, in the best sense of the word, which draws out interest, compassion, and unselfish efforts for those unseen and unknown, living under widely different conditions. A few hints to intending contributors in conclusion. First of all, get full instructions from the Mission depôt you mean to supply, *and keep to them*. This seems absurdly obvious, but it is too often neglected to the great trouble of both parties. As to the packing of the flowers, their case should be well secured, should keep out the air, and not be too heavy. Card-board boxes will not do to go long distances by rail, unless very well secured with brown paper outside and in, for the damp of the flowers softens them and they bulge in, nor do they bear much weight. For small quantities of flowers, or bunches of Violets, for instance, biscuit tins answer very well. As a general rule, the closer the flowers are laid the better they travel, and, above all things, they should not be gathered full blown. However carefully a full-blown Rose or Peony is packed, it is almost sure to fall to pieces when taken out, and is then of no use to anybody; whereas, if the half or less than half-opened bud be gathered, it is easily packed, travels well, and comes out in water to be a thing of beauty for days. All flowers are better gathered in their early stage, though it matters less for Cowslips and Primroses and all of that class. Forget-me-nots are always delightful because they last so long in water, and Daisies travel well; but Buttercups go to pieces at a touch, and the very short-lived wild flowers, as Veronicas and Stellarias, hardly repay the trouble of sending them, they die so quickly. Hawthorns in bud do very well, and Ferns and Grasses are most acceptable, being always useful for making up nosegays. To give any sort of list of flowers is, of course, out of the question; but the mention of a few may be a guide in their selection. Sweet-smelling leaves, such as Sweet Brier and Lavender, never come amiss, and bits of herbs may be mixed with other things with excellent effect. Indeed, when the nosegays are tied up before being packed, which is much the best way for the flowers where it is practicable, it is wonderful to see how much may be made out of the most unpromising materials by ingenious fingers. More particularly in the early spring and closing autumn does this ingenuity display itself, for in the opening season the few flowers to be had are greatly set off by the judicious use of evergreen leaves, or the first green sprays, or the Willow "pussy-cats" so dear to children. Then, when the flowers begin to get scarce in autumn, there is a whole train of leaves and berries which make most attractive nosegays. The brilliant Mountain Ash berries, Braeken Ferns just beginning to turn, deep-coloured Blackberries, even the common Hips and Haws, all combine to replace the flowers. Ivy, leaf, blossom, and berry, is always useful, and, in the places it favours, the ivory-belled, coral-berried Arbutus is a treasure in itself. Of course the Flower Mission can have but limited operations in the winter, but if anybody have any evergreens to spare from church decorations at Christmas time, they would give great pleasure among the many who need all the brightening they can get to prevent the happy Christmas season appearing almost a mockery of their sorrow and suffering. In garden flowers, it is as well to remember that Geraniums will not travel if otherwise than buds, and that Fuchsia heads tumble off if they be very large and heavy. The more delicate Ferns should be well soaked in water before they are packed. Very delicate or very short-lived flowers are not of much use, but within these limits there is hardly anything in the garden which would not be welcome at the Flower Mission depôt. The variegated trees and bushes often grown in shrubberies are very useful, as their leaves set off the flowers so well. If anybody has the means of sending in a basket of fresh-gathered flowers on the distribution day, they will be gratefully received, as the fresher the better, and packing flowers always tells on them more or less. Many people recommend cotton wool as a good thing for packing, and where it can be laid in large sheets at the top and bottom it seems to answer; but generally those flowers come freshest that are packed in a tolerably air-tight box, with a layer of Moss under them, and a few big Cabbage leaves or a sheet of thick paper laid over them. More of these special details can

be obtained from the managers of any of the Mission depôts' whose experience will prove the best guide; and now it only remains for those who have it in their power to bethink themselves whether they cannot do something towards sharing these rich gifts of Nature with others less happily situated? Freely we receive every spring when Primroses and Violets show themselves, and Bluebells come "like a heaven up-breaking through the earth," freely every summer when the Roses blush and glow, freely, too, of autumn gold and winter berries; should we not, therefore, freely give to cheer the weary lives of the sick, the poor, and the lonely?

CONSTANCE O'BRIEN.

The list of all the Flower Mission depôts in London, the addresses of which have been obtained:

- * Home of Industry, Commercial Street, Spitalfields, E.
- * Conference Hall, Mildmay Park, N.
- * Mrs. Raynard's Biblewomen Nurses, 20, Regent Square, W. C.
- * Mrs. Meredith's Prison Mission, Nine Elms, Vauxhall Road.
- * Lamb and Flag Mission, 10, Red Lion Street, Clerkenwell Green. Secretary, Mr. George Soltan.
- * Edinburgh Castle, Rhodeswell Road, Limehouse, E. Secretary, Dr. Barnards.
- * Y. W. C. Institute, 321, Fulham Road, S.W. Secretary, Miss Virgo.
- * 17, South Hill Park Gardens, Hampstead, N.W. Secretary, Mrs. Pitman.
- 14, Nottingham Place, Marylebone Road, Miss Octavia Hill.
- 26, Eaton Square, Miss Rennie.
- 58, Harley Street, Homœopathic Hospital, Mrs. Hale.
- 49, Queen Ann Street, Mrs. Sanderson.
- St. Bartholomew's Hospital, Mr. Jepson, House Surgeon.
- St. Luke's Hospital, Old Street, E. C. The Secretary.
- 18, Conduit Place, Praed Street, Paddington, Miss A. L. Boyle.
- Putney Flower Mission Association. Secretaries, Miss Nelson, Twyford Lodge, Putney.
- Mrs. Barnett, St. Jude's Vicarage, Whitechapel, E.

Those marked thus (*) are in connection with the "Bible Flower Mission."

TEES ON WHICH MISTLETOE IS FOUND.

I CAN endorse "C. E. B.'s" remarks (see p. 145) with respect to the Mistletoe growing on the majority of Apple trees in the orchards of Herefordshire. It grows in abundance on the Aspen; and it may be seen growing upon some Hawthorns in Eastwell Park, Kent, though I do not remember to have seen it growing upon the Apple in that county. There are a few Hawthorns on the side of the drive approaching Ellerton Hall, Shropshire, on which I noticed Mistletoe growing, and though I have not been in that neighbourhood for some time, no doubt it may still be seen there. It also grows upon an Oak in Eastnor Park, Herefordshire, which is the only Oak on which I have seen Mistletoe growing. I find that it is most abundant upon the Apple tree, and rarest upon the Oak tree.—J. T.

— In Forest Hill Park, near Windsor, I have gathered many a goodly bunch of Mistletoe from the Thorn, and the finest berried piece that I have ever seen grew on a Thorn tree in front of the house at Forest Hill. The Lime, too, seems to be a favourite with it in that locality, for on some very tall trees, close to Cranbourne Tower, in Windsor Park, some extraordinary large bunches of it are growing, or were, at the time when I left that neighbourhood, about three years ago. I, however, quite concur with "C. E. B." that the Apple is the tree on which it is found most plentifully in the counties he mentions.—E. F.

— In Stoke Park Mistletoe is very plentiful; right and left of the principal carriage drive it may be seen on the Thorn and on the Lime—most plentiful on the former. On a Damson tree, too, in Richings Park I saw a small plant of it, and a little further off a fine specimen of it on an old Oak. At Stoke Park it grows on the Lime and on the Apple.—T. S.

— Mistletoe grows here abundantly on Apple trees, of which there are numerous orchards in this neighbourhood. It is also found on the Pear, but not so frequently as on the Apple. I have failed to find it on the Oak, although it grows freely on Limes and Thorns.—THOS. COOMBER, *Hendre Gardens, Monmouth.*

— In Savoy I have seen Apple, Pear, and Lombardy Poplar trees laden with Mistletoe, but in this country it is on the Hawthorn that I have noticed it growing most profusely. In Melchbourn Park, Bedfordshire, there is scarcely a tree of the common Hawthorn which does not bear Mistletoe. I never saw it on the Oak, in spite of tradition, and, till now, never heard of any one who had. With respect to "C. E. B.'s" concluding query, two answers are possible—(1) Do not the best antiquaries now agree that Stonehenge and Avebury are the works of a race who preceded the Britons? (2)

May not Oak woods have been cut down, at least in the latter neighbourhood? This I think is, however, improbable, as the Oak does not like chalk.—C. M., *Herne Bay.*

— If "C. E. B.," who writes about Mistletoe, could visit Morehanger, or Muggerhanger, as it is sometimes called, he would find Mistletoe growing freely on the White Thorn, some bushes being so overrun with it that scarcely any of the Thorn was left. To me, however, the most singular circumstance was seeing Mistletoe growing on Roses; in some gardens a basket bed of Roses and Mistletoe was not uncommon; we have it growing here on the Lime; the Apple trees at Morehanger are covered with it.—G. H., *Bedford.*

— Mistletoe may be seen in great quantities in Windsor Park on Poplars, Oaks, Birches, and other trees, but especially on the Thorn, on which it seems to be quite at home. I have seen it growing on Thorn and Apple trees in Kent; I have also once seen it growing as far North as Scotland on an Apple tree in Midlothian.—J. F. S., *Pitcaple Castle, Aberdeenshire.*

Judging Cottage Gardens and Allotments.—"E. H.'s" remarks (see p. 161) are very appropriate, but would it not be desirable to offer one set of prizes for the best kept and best cultivated garden, and another set for allotments? It is difficult to judge both in one class. The system of cropping allotments is different from that of gardens, and necessarily so, for in many cases—in fact, in almost every case that has come under my observation—allotments are a long distance off from the cottages to which they belong, and frequently near woods or plantations, and liable to be overrun with game. They generally contain such crops as Potatoes, Wheat, Beans, Barley, and Oats, and I have often found as many degrees of excellence in the cultivation of these plots as are to be found in gardens; but where the two are brought into competition with one another, the gardens always carried off first, and generally, second prizes. I may mention that in a district competition in 1875, one hundred gardens and seventy-four allotments were entered for competition, the district including many parishes. Altogether forty-four prizes were offered, or four for each parish, and only four were taken by allotments, one second, one third, and two fourths. Such a result made it desirable to make two classes, one for gardens and one for allotments, which was done last year.—J. M.

NOTES AND QUESTIONS—VARIOUS.

La Grosse Sucree Strawberry.—We put fifty plants of this Strawberry in an early Vinery the second week in January, and all but two have thrown up fine, strong trusses of blooms, which are now well set and thinned, and promise to produce fine fruit. The temperature has been higher than what is usually recommended in which to set Strawberries. As the present is a good time for planting strong plants to supply runners for next year's forcing, perhaps this note may be of service.—H. J. C., *Grimston.*

Setting in Peaches and Nectarines.—These have set abundance of fruit, although during the time they were in bloom there were not more than two days' sunshine. During these last fifteen years I have always put a hive of bees in the house when the trees were in bloom, and although both top and front air is left on the bees do not leave the house, doubtless owing to the coldness of the outside air.—RICHARD NISBET, *Aswarby Park, Folkingham.*

Arbutus magnifica.—This is better known than your correspondent (see p. 114) seems to think. It is the best out-of-door shrub which we have in December, and any one who has not got it would do well to procure it at once. It is a plant which withstands cutting well. I use not only its berries, but the flowers, extensively in a cut state, the latter associated well with Poinsettias and Euphorbia jacquinielora, drooping so gracefully as they do over the sides of vases, and the foliage contrasts strikingly with the showy bracts of the Poinsettia.—E. MILLER, *Old Sneyd Park, near Bristol.*

Cutting Privet Hedges.—This is the best season for reducing overgrown Privet hedges, and a good sharp hook with a rather long handle is the best implement to use. Privet will bear cutting into the hard wood now, and will soon break and become green again. It being a strong-growing and rooting plant, rather strong measures are required occasionally to keep it within bounds.—E. HOBDAV.

Holly Berries.—In the winter of 1875-6, quantities of Hollies were moved from one part of the ground here to another, and, singular to say, those that were undisturbed did not produce a berry, while those that were transplanted became loaded with them. I should mention, however, that all those that bore berries were barked by rabbits, but that those on which there were none were not touched. I have not the least doubt that the removal induced fertility, and the circumstance tends to show that ringing or half-ringing has the same effect.—N. F. FULLER, *Oakham.*

Cure for Bleeding in Vines.—Mix up flour and water to the consistency of a piece of putty, and apply it to the cut surface, tying a piece of cloth over it; this with me has proved an effectual remedy.—N. J. G.

The Late Mr. Ormson.—We are informed that the business of horticultural engineer, and manufacturer of hot-water apparatus carried on so successfully by the late Mr. Ormson, at Stanley Bridge, Chelsea, will be carried on as heretofore under the same name.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

MARCH 7.

THIS meeting, like the last, was held in the large conservatory itself. Just now an attractive promenade—a fine tree of the scarlet-flowered Indian *Rhododendron arboreum* being in great beauty, as well as other smaller decorative plants, the whole intermixed among masses of Tree Ferns, Palms, and other vegetation, which formed an agreeable background to the beautiful groups of Orchids, *Cyclamens*, *Cinerarias*, *Amaryllis*, and other plants, contributed so profusely both by amateurs and nurserymen. Messrs. Veitch & Sons sent a choice collection of hybrid and other Orchids, new seedling varieties of *Amaryllis*, Ferns, Palms, and other decorative plants. Mr. B. S. Williams and Mr. Wills also furnished good miscellaneous collections of ornamental plants; and a fine display of *Camellia* blooms, contributed by Mr. W. Paul, of Waltham Cross, was much admired; Mr. Turner likewise showed *Camellias* and a group of scarlet-berried *Aneubas*. Mr. Michaels exhibited a collection of *Phalenopsis* and other Orchids; as did also Sir Henry Peck and Mr. W. Terry, of Peterborough House, Fulham. Some *Cinerarias*, shown by Mr. F. Watson, of Isleworth, were remarkable for brilliancy and novelty of colouring.

First-class Certificates.—These were awarded to the following new or rare plants:—

Perpetual-flowering Carnation, Rose Perfection (Turner).—This is a free-growing variety, which bears well-formed rosy or cerise flowers, very rich and striking in a young state. For decorative purposes or cut flowers, it will doubtless be a valuable variety.

Perpetual-flowering Carnation, Gueldres Rose (Turner).—A free-growing variety, bearing very full white flowers. Like the last, it will be useful for winter and spring-blooming indoors, or for cut flowers.

Rhododendron Taylori (Veitch).—A vigorous and free-flowering greenhouse hybrid belonging to the *R. jasminiflorum* and *Javanicum* section, and bearing clusters of wax-like, rosy-lipped flowers, the long tubes of which are white. Like those of the other varieties of this section of *Rhododendron*, the plants flower several times in the course of a season, and succeed well in a warm greenhouse temperature.

Eurycles australasia (Veitch).—This plant, popularly known as the Brisbane Lily, bears erect, umbellate clusters of pure white, *Hæmantis*-like flowers on a short scape; the leaves, which attain their full size after the flowers have faded, are large and similar to those of some *Funkias* in shape, but of a fresh and pleasing shade of pale green, as bright as if varnished. The plant grows and flowers freely, and will be especially useful for decorative purposes or for cut flowers.

Osmunda palustris (Veitch).—This is an elegant-habited species, the soft green, brownish-red-tinted fronds of which remind one of those of *Adiantum tinctorum* in colour. They measure from 15 in. to 18 in. in length, and are tripinnate, the smaller divisions being oval or ovate, and nearly 1 in. in length. The plant grows freely, and well deserves attention.

Dracæna terminalis alba (Wills).—An important acquisition, having quite the habit and character of the well-known *D. terminalis*. The leaves are lanceolate, the ground colour bright green, with bold, pure white variegation, the upper leaves being white, with here and there a stripe of green, and, in some cases, large patches are coloured white, while the rather elongated leaf-stalks are also edged with white. It will be a useful variety for general purposes.

Cineraria, Mary (James).—This, perhaps, is the most perfect *Cineraria* hitherto raised, the petals being broad and smooth, and the whole flower circular and of great substance. It is one of the very few seedling *Cinerarias* we have yet seen worth naming. Its colour is a silvery rose.

Cineraria, Thomas Winter (James).—A rich maroon-purple, self-coloured variety like the last, but not quite so perfect in petal and outline.

Azalea, Mrs. Carmichael (Williams).—This is a cross-bred plant, closely resembling the well-known *A. amoena* in habit of growth. The flowers, which are freely produced, are much larger than those of the last-named sort; they are of good form, more than 1 in. in diameter, and of a rich lilac-purple colour. This variety is a welcome addition to early-flowering *Azaleas*, and one which will also be useful for forcing.

Dennstaedtia davallioides Youngi (Veitch).—A vigorous-growing Fern of a somewhat creeping habit, the ample bright green fronds of which are 4 ft. in height, and finely cut into slender pinnæ. It promises to become useful for general decorative purposes.

Dendrobium crassinode Barberianum (Sir T. Lawrence).—A richly coloured form of the thick-jointed *Dendrobe*, the sepals and petals of which are tipped with rich magenta carmine instead of lilac as in the typical species. It was imported by Messrs. Low & Co., of Clapton.

Miscellaneous Plants.—From Messrs. Veitch & Sons came a select collection of Orchids, including a unique specimen of the hybrid *Laelia Veitchii*, several other hybrids, and a group of new hybrid and seedling *Amaryllis*; also a remarkably well-grown group of crimson, purple, and white

Persian *Cyclamens*. Among the Orchids we noted *Odontoglossum trinophanum*, with slender five and seven flowered spikes of golden-brown blotched flowers; the golden-lipped *Oncidium varicosum*, *Masdevallia chimera*, the pure white *Lycaste alba*, and several varieties of *L. Skinneri*; a plant of the fresh green-leaved *Bletia hyacinthina*, an old Chinese terrestrial Orchid, bore six or eight spikes of vivid purple flowers or buds. Among the seedling *Amaryllises*, one named *Junius* was especially noticeable as having the vivid crimson-scarlet colour of *A. Ackermannii pulcherrima*, and in being moreover of a much better shape. *Clio* (scarlet) and *Thalia* (reddish-crimson) are also desirable kinds, which received certificates last season. *Lily Musgrave* deserves notice as being a well-formed flower of a soft red colour with a greenish ray. Sir Trevor Lawrence, brilliant *Crimson*, well deserves a place in the most select collection. *Constance* and *Madame Titien* are likewise two of the best of the lighter-coloured kinds. Mr. Newman, gardener to Mr. W. H. Michaels, Cholmeley Park, Highgate, sent a group of *Phalenopsis*, among which were good examples of *P. Schilleriana*, *P. amabilis*, and *P. grandiflora*. *Dendrobiums* in this collection were represented by *D. thyrsoiflorum*, with white sepals and petals, and a yolk-of-egg coloured lip; a large and richly-coloured form of the Trumpet *Dendrobium* (*D. lituiflorum*); and a well-flowered but pale-coloured *D. crassinode*. The chaste little *Colax jugosus* was represented by a small-flowering plant, the sepals of which are pure white, and the petals white, barred or spotted with brownish-purple, the trowel-shaped lip being blotched with purplish-blue. Perhaps the most singular Orchid in this group was the old but rare *Houlletia Brocklehurstiana*, a plant having the ovoid, fluted bulbs and plaited leaves of a *Gongora*, and a pendent spike of five and six rich brown and purple flowers. Mr. Ollerheal, gardener, Wimbledon House, sent a miscellaneous group of Orchids, among which we noted the *Barkeria*-like *Epidendrum non-inense*, bearing slender spikes of lilac-speckled flowers. Two or three excellent varieties of *Phalenopsis Schilleriana*, *Dendrobium lituiflorum*, with from forty to fifty rich purple and white flowers, and a richly-coloured variety of *D. crassinode* named *Barberianum*. Mr. W. Terry sent a small group of Orchids, among which was a very large-flowered form of *Cymbidium eburneum*, also three plants of *Vanda suavis*, *Oncidium serratum*, *O. sarcodes*, and the graceful old green-sepalled, white-lipped *Brassavola venosa*. Mr. Petridge, of the Boston Park Road Nursery, Brentford, showed a large-flowered *Cyclamen persicum* named *magnificum*, the flowers of which are white, and the base of the petals carmine. Mr. Charles Turner sent a well-grown group of white *Camellias* in flower, associated with well-berried plants of the green-leaved *Aneuba japonica vera*, and also a box of cut *Camellia* flowers, including twenty-four of the best white, rosy, crimson, and striped kinds. Messrs. W. Paul & Sons, of Waltham Cross, sent twelve stands of cut *Camellia* flowers, comprising about seventy varieties. Mr. James, gardener to W. F. Watson, Esq., of Isleworth, contributed a collection of dwarf, well-grown, large-flowered *Cinerarias*, the most striking colours being purple, maroon, blue, rose, lilac, either self-coloured or in combination with more or less white in the petals. This strain is certainly a most desirable one, the plants being especially dwarf, and the flowers excellent in form. A specimen of *Dendrobium Pierardi* was shown from the Duke of Westminster's garden at Eaton Hall, near Chester, and was universally admired, it being one of the finest examples of this beautiful Orchid ever exhibited. It bore eighteen wreath-like pseudo-bulbs, several over 4 ft. in length, and bearing no fewer than 114 flowers. A large and varied group of seedling *Primroses*, *Polyanthuses*, and *Myosotis dissitiflora* (little tufts in 48-sized pots, thickly studded with pink and blue flowers, each flower being from one-third to half-an-inch in diameter), was contributed by Mr. R. Dean. The soft lilac *Primula denticulata* was also well represented in this group, as was also its larger and deeper-coloured variety, *P. purpurea*. Messrs. Paul & Son, Cheshunt, sent flowering plants and young growing specimens of *Fortune's Yellow Rose*, and also plants of the variety which has been named *Beauty of Glazenwood*; in foliage and flower, however, both varieties are identical in every way, a decision unanimously arrived at by the Floral Committee. Mr. John Wills exhibited six of his new seedling *Dracænas* in excellent condition, the varieties being *D. Elizabethæ*, *D. salmonæ*, *D. Gladstonei*, *D. Rebecca*, *D. Sidueyi*, and *D. terminalis alba* (to which a first-class certificate was awarded). Mr. Wills also contributed a large miscellaneous group of decorative plants, consisting of Ferns, Palms, Orchids, *Azaleas*, &c., gracefully fringed with *Isoplepis gracilis* and creeping *Ficus*.

Fruit.—Messrs. Thomas Rivers & Son, Sawbridgeworth, sent large, shapely, and highly coloured Oranges of home growth, the varieties being *St. Michael*, *Maltese Blood Orange*, and the *White Orange*. Mr. E. Bennet, of Ribley, showed a punnet of *Gairibaldi* Strawberries of excellent quality, the fruit being large and highly coloured.

Rhododendron Exhibitions.—We understand that the Hurlingham Club has made arrangements with Messrs. John Waterer & Sons, of Bagshot, to hold an exhibition of *Rhododendrons* in the gardens at Hurlingham house, Fulham, during the month of June next. Mr. Isaac Davies, of Brook Lane Nursery, Ormskirk, has also arranged to exhibit his sweet-scented *Rhododendrons*, *Azalea mollis*, and other plants, at the Winter Gardens, Southport, at about the end of the present month.

Horticultural Societies.—Following the example of the Belgians, the Italians propose combining the chief horticultural societies of the kingdom into a Horticultural Federation, and to hold periodical exhibitions at Milan, Venice, Florence, Turin, Naples, Rome, and Genoa—the first to take place at Milan in 1878, the second in Florence in 1880.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

NOTES OF THE WEEK.

IRIS RETICULATA AND ITS SEEDLINGS.—In reply to "H. M." I do not know that I can add much to the replies published in your last number, except to warn cultivators of this beautiful plant not to grow it in light soil, as it evidently likes a good substantial loam. My soil is almost more than a substantial loam, and it grows and increases here in a very wonderful way, and I do not find it so short-lived as your correspondent seems to do. If forced the process should be very gentle, not giving it more than warm greenhouse treatment. My object in writing this is to give a caution much needed by many amateurs, and I fear many professional gardeners as well, about the treatment of bulbs and tubers. After the flowering period, the pots are often stowed away under stages, or set out on the ground in any out-of-the-way place, and get thoroughly neglected, "dried off gradually" according to "H. M.'s" practice, but very frequently by a more rapid process—destruction must be the result of any but a natural treatment. When such plants are growing out-of-doors there is no gradual diminution of the water supply, nor should there be when the plant has the disadvantage of growing in a pot; on the contrary, a full supply of water and careful management should be given till the foliage dies away. I would recommend growers of *Iris reticulata* to look carefully after seed, and to raise as many seedlings as they can: I am blooming a small batch of them this spring. No two are alike, and none of them resemble the parent closely; two of them are so distinct that they are worth increasing and cultivating as garden varieties.—J. G. N.

THE NEW SCARLET WINDFLOWER.—This, which we this week figure, is a finer plant than the plate gives notion of, many of the plants as yet in culture being young and weak, and from one of such our plate was prepared. In the garden of M. Henri de Vilmorin (to whom we are indebted for the remarks that accompany the plate) there are several thousands of the plant in various stages. During the past week we have seen flowers from this garden measuring 4 in. in diameter and even more. It may be added, that the plant is distinct from any of the varieties of the old garden *A. coronaria*.—R. N.

MARCH IN MONTREUIL.—In this village of Peach-growers, the pruning of the trees is now being carried on, and will not be completed before another week is past. The trees are scarcely in flower yet, though some kinds have opened their blooms. They are all protected by a wide temporary coping of boards or of straw mats. In M. Chevallier's garden interesting and apparently successful experiments are being carried out in half-breaking across shoots and branches with the view of inducing a healthy growth below the said break. In this way M. Chevallier says he gets surprising results—the very kind of fruitful shoots he desires. In many cases where we would remove a shoot, it is slightly cut, and then broken half through. Good growths start from below the break, while perfect fruit is gathered from above it.—J.

NEW DOUBLE WHITE EPACRISSES.—Two plants of double-flowered Epacrisse, which are now in bloom in Mr. Ball's nursery at Chelsea, deserve notice on account of their great beauty. The two forms differ in size, and slightly in the colour of their perfectly double flowers, and although the larger-flowered, pure white form is by far the most effective, both well deserve culture. In the smaller-flowered plant the blooms are white, delicately flushed with rose. Both kinds appear equally vigorous in habit, and doubtless are varieties of *Epacris onosmodora*, the colour of which in the normal or single-flowered condition varies from pure white to rosy-purple; hence the variation of colour shown by these new double forms is not surprising.—B.

SEEDLING HIPPEASTRUMS.—An attractive collection of seedling *Hippeastrums* is now in flower in Messrs. Veitch & Son's nursery at Chelsea. These are mainly the result of cross-fertilizing such kinds as *H. Ackermannii pulcherrimum* (which for brilliant colour is unrivalled), *H. pardinum*, and *H. Leopoldi*, and among them are some well-shaped and brilliant forms. One of the best is certainly *Janins*,

a kind which retains much of the colour of *H. Ackermannii*, added to a superior breadth and smoothness of petal. *Hippeastrums* are so easily grown and forced into bloom at almost any period of the year that no collection even of ordinary decorative plants should be without them.—B.

SEEDLING CINERARIAS.—Messrs. F. & A. Smith, of Dulwich, have sent us a remarkable collection of *Cineraria* blooms, many of which are well-nigh perfect in outline, breadth, and smoothness of petal, and in richness and variety of colour. Among other variations we observed some white-eyed flowers, in which the marginal colouring was shaded as in the Alpine *Auricula*, an innovation which adds much to the finish and delicacy of the blooms.

GESNERA HOUTTEI.—Quantities of plants of this *Gesnera*, which was raised at the Wellington Nursery a few years ago, are now flowering profusely at Pine Apple Place. The flowers, which are long and tubular, are brilliant crimson, and, unlike those of other *Gesneras*, last in good condition on the plant for a considerable time in a cool airy house. For conservatory ornamentation this plant is deserving of extensive cultivation; it is easily managed, excellent in habit, and when furnished with clusters of from forty to fifty buds and flowers on the point of each shoot, unsurpassed as regards effect at this season of the year. After flowering, the plants may be moved to any out-of-the-way place in a cool-house or pit; and if a few of the bulbs be shaken out, potted, and placed in a warm temperature in succession, they will produce handsome plants laden with bloom from January to May.—J. S.

DOUBLE-FLOWERED CHINESE PRIMROSE.—We have received from Mr. Gilbert, of Burghley, a boxful of these popular flowers—all good, but two unusually large and double. One is a full, smooth-petaled flower of snowy whiteness, $1\frac{1}{2}$ in. in diameter, and frilled around the margin. The other is a similar flower in all respects but colour, which is of a clear rosy tint. Either for decorative purposes or cut flowers these are well worth careful culture.

GUELDER ROSES FOR FORCING.—Few hardy shrubs are more ornamental at this season than well-grown specimens of the common Guelder Rose, when laden with large, drooping, snowball-like blossoms. Plants in 8-in. or 9-in. pots may have been seen in this condition for a long time past in the Exotic Nursery, Chelsea, each bearing upwards of twenty large and well-formed clusters of blossoms. Messrs. Veitch use these plants chiefly for room decoration, a purpose for which they are well suited, as they look well under gas-light. The blossoms, too, last for a considerable time in good condition in a cut state.—C. S. W.

GREEN PEAS.—These are now seen on every stand in the Paris market, and are very cheap, from 1 fr. the litre (shelled) to 4 fr. for the smallest and freshest Peas which come from Toulon. Generally, the Green Peas seen at this season in the Paris market come from Algiers. They have been abundant there for the past six weeks; one could wish they were equally abundant in London.—V.

PULMONARIA AZUREA.—This is a very handsome spring-blooming kind, which produces large clusters of showy flowers on dwarf rigid stems. The flowers when they first open are dull red, gradually changing to light blue, and then to a lovely deep blue—about the colour of *Myosotis azorica*. In the course of a few days this *Pulmonaria* will be in full beauty in the York nurseries, where I have seen it grown in small pots, forming complete masses of flower, resembling a dwarf *Forget-me-not*. It is a very easy plant to cultivate, and will grow in almost any kind of soil, but is prettiest when grown in a rather poor, dry, and hard soil. It may be planted in sunny or shady positions; as it will grow equally well in either situation.—R. P.

ORCHIDS IN BLOOM AT TWICKENHAM.—The Orchid-house in the gardens at Poulett Lodge, Twickenham, is now very attractive, containing, as it does, many large and healthy well-flowered specimens. Amongst these may be mentioned a plant of *Dendrobium Primiinum* growing in a basket, with five or six strong stems, each bearing from fifteen to twenty delicately coloured blossoms. D. Pierardi, growing in a suspended basket, is furnished with scores of long, thin, pendent stems, clothed with multitudes of delicately tinted greenish-white flowers; D. Wardianum, with from forty to fifty blooms; and numerous plants of *Phalænopsis grandiflora* and *P. Schilleriana* are bearing spikes with upwards of fifty flowers of unusually large size, many of them measuring as much as 4 in. across the petals. These, associated with the gracefully-drooping foliage of *Cocos Weddelliana* and *Seaforthia robusta*, have a good effect. Large plants of *Dendrobium nobile* and *D. corulescens*, grown in deep pans, are each bearing no fewer than 200 fully expanded blooms, and, being arranged singly on the stages of the house, are remarkably attractive. *Lælia anceps* is also in very good condition, strong healthy plants of it bearing from ten to twelve long

drooping spikes, each surmounted by five or six large, rich, violet-coloured flowers. In addition to the above, *Dendrobium chrysalinum*, *D. sanguinum*, *D. Cambridgianum*, and *Anthurium Scherzerianum* are also flowering freely, and are in excellent condition. The Orchid house here is painted green, a colour which contrasts well with the bright flowers.—C.

GNIDIA PINIFOLIA.—This useful, old-fashioned, hard-wooded, greenhouse plant, though seldom seen in good condition in private establishments, nevertheless, well deserves a place in every garden in which spring-flowering plants are required for conservatory or greenhouse decoration. Numbers of it in Messrs. Rollisson's nursery are now producing a profusion of trusses, consisting of small, white, deliciously-scented blossoms; they commenced blooming three or four weeks ago, and will, in all probability, last in good condition until the end of April. Unlike many hard-wooded plants, this, under ordinary good culture, never fails to flower freely from every shoot.—W. S.

ABUTILON DARWINI TESSELLATUM.—This is without doubt the best of all the Abutilons for growing in 6-in. pots for the decoration of the conservatory, or as table plants. Cuttings of it struck in the autumn and potted on make handsome little plants by January or February. It is grown in this way at Poulett Lodge, Twickenham, where several dozen plants of it, from 12 in. to 15 in. high, and as much through, are literally laden with bell-shaped, ochre-coloured blossoms, the latter forming a fine contrast with the yellow and green tessellated leaves.—W.

SAXIFRAGA CRASSIFOLIA IN POTS.—This forms an admirable plant when flowered in pots, as it may now be seen in the greenhouse at Kew. The flowers, which are produced in great profusion, are more delicate in colour, and the trusses much larger than those on plants in open borders. Strong plants of it, lifted in autumn, potted, and gently brought on in a cool frame or pit, might be had in flower from soon after Christmas until the end of March, with little or no trouble. The white-flowered variety of *S. crassifolia* would be especially valuable, grown in this way.—S. W.

DENDROBIUM WARDIANUM LOWII.—This may now be seen in great beauty and profusion at Tretham, where, suspended from the roof of a high lean-to-house, the stems of a large quantity of plants laden with floral treasures dangle amidst Palms, Pitcher Plants, and Ferns. This is the best way in which to show off the beauty of this species of Dendrobe to advantage. Scarcely less beautiful, too, is the variety of *Dendrobium crassinode* called *Barberianum*. This, in the same house, is furnished with a wreath of blossoms some 2 ft. long.—S.

INDOOR CLIMBERS IN FLOWER AT KEW.—It may interest some to know what plants are at present most attractive on the roofs of houses at Kew, inasmuch as at this time of year good flowering climbers are comparatively scarce. *Bignonia purpurea*, a plant seldom met with anywhere but at Kew, is well worth cultivation, for the sake of the bright purple and striped trumpet-shaped blossoms which it produces in large quantities in a warm temperature; *Clerodendron volatile* and *C. speciosum* are also just now flowering freely here, the former producing large trusses of creamy-white, and the latter rosy-pink, blossoms; *Euphorbia splendens*, trained up the roof of the Cactus-house, is strikingly attractive, being furnished with hundreds of bright scarlet blossoms; *Bomarea Caldesii*, twining up some trellis-work at the end of one of the houses, is laden with large clusters of bright, *Alstromeria*-like blossoms; and the old but highly ornamental and useful *Kennedyia rubicunda* is thickly beset with showy, blood-red, Pea-shaped flowers; *K. ovata rosea* is also in equally good condition, and the blossoms of both are valuable for button-hole or other small bouquets. The white, star-like blossoms of *Clematis indivisa* are still being borne by hundreds on multitudes of long, pendent, wiry stems; for covering the roofs of cool greenhouses, and for producing a profusion of gay flowers during the winter and spring months, this *Clematis* is excelled by few plants. *Lonicera sempervirens*, too, a valuable plant, is well furnished with scarlet, orange-tipped, tube-shaped flowers, which are produced in large trusses from the point of every little shoot; for trellised walls of greenhouses, this is a valuable plant, but for roof drapery the shoots are scarcely sufficiently graceful.—S.

SUBJECTS FOR TRIAL AT CHISWICK.—The Council of the Royal Horticultural Society propose, instituting at the Chiswick Gardens, this season, under the direction of the Fruit and Floral Committees, comparative trials of the following subjects, viz., Vegetables—Tomatoes, Cabbages, Savoys, Turnips, New Peas, and New Potatoes. Flowers—Euphrasies, Gloxinias, Begonias, Cannas, new Zonal Pelargoniums, Stocks, Asters, and new annuals. Fellows of the Society and those desirable to contribute subjects for this purpose will please communicate with the Secretary, or Mr. Barron, superintendent, at the Royal Horticultural Gardens, Chiswick.

HERBACEOUS PLANTS SUITABLE FOR BEDS.

It is impossible with such a mass of flowers as beds of *Campanula carpatica* (see p. 152) produce, to keep picking off daily all fading blooms, which one can manage in the case of individual plants of this and other *Campanulas* in the mixed border, and there is no doubt by so doing a certain amount of bloom is kept up to the end of the season, still not to compare with the mass of bloom produced in early summer; and for autumn I think many will turn to a bed of *Lobelias* or blue Pansies. For those, therefore, who must have a quantity of flowers in autumn, I would suggest our plan of planting thickly between the clumps of *Campanula*, *Colchicum autumnale*, one bed of the lilac, another of the white or the double varieties, or mixed according to taste, and clipping over the *Campanula* neatly with the shears, thus removing all flower-stalks, and having a completely new bed for autumn. The *Colchicum* leaves are at present a great improvement to the beds—fresh and green, 4 in. high, while the *Campanula* is just showing above the soil. I do not deny that the fading leaves of the *Colchicum* are an eyesore for three weeks, but we put up with that necessity, and on no account remove them until ripe. *Campanula Hostii* and others of that growth, we find very persistent bloomers, and the erect-growing stalks are more quickly removed than those of *C. carpatica* or *turbinata*. All blue seedlings of this latter that I have seen are inferior to the true plant, and our practice is to increase our plants by tearing up the roots of the original stock. *A propos* of *Colchicum* planting, I had a charming arrangement—a narrow border (78 ft. long) of *Helleborus angustifolius*, edged with the double lilac *Colchicum*, but the border was within the reach of Willow trees, and the *Colchicums* were hopelessly covered with their intolerable, small leaves, for which there is no remedy. The *Hellebores* were, of course, all right, as they flowered long after the leaves were down and away; and I mentally resolved only to plant autumn-flowering bulbs in open quarters away from trees, which is their natural habitat. A bed really worth seeing is one of *Oenothera missouriensis* or *O. macrocarpa* (the red-spotted calyx of the latter makes it best) edged with a broad band of *Campanula carpatica*. It is faultless; but we cannot get a stock of the *Oenothera* now-a-days. Twenty years ago we gave away hampers full of them from our beds, unplaiting the roots, which never required to be cut; young plants came away of themselves, and by re-planting the parent roots, our beds were as full as ever. Now I can neither give nor get anything but cuttings, which somehow never come to any good, and two or three plants in the mixed border are not satisfactory; such sprawling growers look much better in a mass. Our last work, regularly at 6 o'clock p.m., was to pick over these beds, removing the seed-vessels as well as the faded flowers; it was tiresome, but absolutely necessary to keep them as they were—the admiration of all who looked on them. Blue branching Larkspur makes a much more persistent bed (of course, not letting it seed) than any of the herbaceous *Delphiniums*, which, although flowering twice, require a long interregnum to produce a second crop.

Wardie Lodge.

Judging Allotment Gardens.—I have read with interest the remarks on this subject (see pp. 161 and 203). We have a Cottage Garden Society in this parish which seems to succeed well. The cottage gardens and allotments are judged separately about the middle of July by judges selected from the adjoining parishes. The vegetables must not exceed a certain number—say ten or twelve; to each sort so many points are given—for a first-rate crop, three; second-rate, two; ordinary, one; inferior crops are disregarded, the prizes being awarded according to the number of points. These competitions have been a great encouragement to the cottagers, both allotments and gardens being remarkably well managed. Flowers are also taken into consideration. Good general vegetables only are grown, Potatoes being the principal crop; no corn of any kind is cultivated: there is no restriction with regard to it, but it would not pay. This being a large parish, consisting of upwards of 9,000 acres, the allotments are in four or five different places for the convenience of the cottagers.—JOHN GARLAND, Killerton, *Essex*.

Dandelion.—Notwithstanding the abundance of delicate cultivated salads in the Paris market, the common Dandelion is as abundant there as any other, and is even sold at as high a price as some of the cultivated salads.—V.

THE FLOWER GARDEN.

EARLY PERSIAN IRIS.

(*I. PERSICA*).

A WEEK or two ago we received fresh and beautiful flowers of this plant from a warm sandy garden in Surrey, together with the information that the bulbs were planted six years ago, and that they had flowered every year since. This Iris is one of the most attractive and distinct of all the early-blooming kinds, and it is one which well deserves a place in all collections where the soil is warm and dry. The annexed sketch represents a flower of it, natural size, and also a bulb and foliage. Its blossoms, which are produced from a tuft of bright green leaves that just peep above the soil, are white suffused with a pale Prussian blue tint, the broad ends of the fall petals being blotched with velvety purple, a colour which contrasts well with the golden yellow keel. This Iris is a native of Persia, and has long been in cultivation in this country, although like nearly all the other bulbous species it is not very plentiful. Singularly enough it was the first plant figured in the "Botanical Magazine," whence we learn that the best bulbs of it at that time were imported from Holland, and that they flowered well in glasses of water, or better still in pots of moist sand or sandy soil. About two centuries before the plant was figured, however, in the "Botanical Magazine," Parkinson alludes to it in his "Paradisus" (1629), as being cultivated in his time, but states that it rarely bloomed. If bulbs be still obtainable from Holland at a cheap rate, this plant well deserves indoor culture, inasmuch as its delicately coloured, and agreeably fragrant flowers would associate well with those of other forced bulbous plants. In habit of growth this species very closely resembles *I. colchica*, and one or two others of the winter and spring flowering bulbous Irises, and these may be grown along with it on well-drained sandy soils. In its native habitats in Asia Minor, *Iris persica* is found at an elevation of 6000 ft. One of its allies, *I. canasica*, is just opening its honey-coloured flowers in a garden at Tooting, and is harder than *I. persica*, although from nearly the same region, where it is found on the mountain slopes at from 7000 ft. to 8000 ft. above the sea level. *I. alata*, another near relative, flowers in December, and is a very pretty species to which we alluded in Vol. X. of THE GARDEN, p. 579.

B.

SNOWDROPS.

In your article on the genus *Galanthus* (see p. 194) you have omitted to notice at least two species or varieties, one of which is said to be by far the finest of the whole. It was described in a paper read at the Botanical Congress at Florence in 1874, and was recently published under the name of *G. Regina-Olgæ*, and is found in the mountains of northern Greece, where it flowers in autumn. *Galanthus Redoutei* is another variety from the Caucasus, which I received from Dr. Regel, of St. Petersburg, and flowered this winter, but not in a strong enough state to enable me to form an opinion as to its distinctness. I would also point out that neither the figure nor description of *Galanthus Elwesi* in THE GARDEN gives a good idea of the plant. Though its scape, flower, and leaves are not quite so long as they are in *G. Imperati*, it cannot be called dwarf. It is distinguished by its very globular flower, which is twice as broad as that of *G. Imperati*, and by the green base of the inner segments, which show between the outer ones. The leaves are also very glaucous, and can be distinguished at a glance from those of any other Snowdrop. The bulbs which Mr. Barr had, being weak and starved, did not bring their flowers to perfection, as will easily be seen by examining the plate in the "Botanical Magazine," which represents the plant very fairly. I very much doubt whether *Galanthus Imperati* has any character except size by which it may be separated from *G. nivalis*, though from a horticultural point of view it is distinct enough. The *Ornithogalum* from Asia Minor, mentioned (see p. 190) as flowering in Mr. Barr's grounds, is probably *O. fimbriatum* (Bot. Mag., 5077), which has been in bloom here for weeks.

H. J. ELWES.

Preston, Cirencester.

Early Persian Iris (*I. persica*).

Cheilanthes odora.—Plants of this little Fern, when well established and the fronds fully developed, are beautiful objects. Its general aspect reminds one of the North American *Cystopteris bulbifera*, but it is both dwarfer and more compact; the fronds, too, are evergreen, which adds greatly to its usefulness. Although the odour of this lovely little Fern is not always perceptible, yet at times, especially early in the morning, when removing the frame-lights, the perfume is, though delicate, most delicious. I have found it to thrive best planted in a compost of loam, peat, and small pieces of stone (smashed granite), with the addition of a small portion of white sand; it is doubtless a sun-loving plant. Three varieties of it have been found in Southern Europe, on elevated regions, growing under overhanging ledges of rock, with a south aspect. Those that have

succeeded best with me are grown in pots in a frame facing the south and fully exposed to the sun's rays, but with little air admitted. I may just add that plants of it have been exposed throughout the winter on the rockwork at York, and have not sustained the slightest injury.—R. P.

YUCCA PICTA AND ITS SEED-PODS.

UNDER this name I received, a few years ago, a plant from Belgium, described in the catalogues of 1877 as "having a large stripe of pale green in the centre of each leaf." It appears to be a dwarfish variety of *Yucca aloifolia variegata*, the foliage being dark green with a stripe through the centre less conspicuous and clear than in *Y. aloifolia variegata*. Its habit does not appear nearly so free and vigorous, although I have kept it in a small pot for want of space. Standing out in a sunny position in the open air during the past summer, I was somewhat surprised to see that it was throwing up a flower-spike; in the course of a week or two, three or four of the flowers were expanded, there being only about a dozen in all; it appeared rather distinct, having yellowish-white blossoms, but nothing peculiar to make them of very particular merit. Some days afterwards, on examining the plant again, I found it had four seed-pods, then already nearly 1 in. long; although the *Yuccas* seed abundantly in the Southern States, I had never before observed any seeds upon the same kind. *Y. filamentosa*, cultivated in abundance everywhere, flowered with me for more than forty years; and as I had just read Mr. Hemsley's account of all the *Yuccas* in 'THE GARDEN' (Vol. VIII., p. 129), and noticed his remarks in regard to the seeds rarely being seen in English gardens, it occurred to me that a brief notice of this species or variety might not be unacceptable to some of your readers. Mr. Hemsley states that the "most readily seized characteristics for distinguishing the species are furnished by the leaves, and particularly by the seed-vessel, but as the latter is rarely seen in this country it may be put on one side altogether, and we must rely upon the differences in the leaves and such other characteristics as are seen and understood." I therefore give a description of the seed-pod of *Y. picta*. When fully developed it is 3 in. long and 1½ in. in diameter, hexangular in form, blunt at the base, and rounding off to the point. Three of the sides or angles alternately are covered with a hard, thick, and fleshy substance, with a prominent division line commencing ¼ in. from the stem and running to a projecting point; the other three sides or angles with a soft, thin, membranous covering, more or less finely veined in lines, radiating from an apparent midrib, running longitudinally through the centre, quite smooth and glossy on the surface; the fleshy angles dark brown; the membranous ones very smooth, glossy, and very dark purple when mature. The interior is filled with a fruity or fleshy substance, in which the seeds are deeply embedded in six longitudinal rows. Of the origin of this variety I have no knowledge, and that it should produce seeds so freely I am unable to account. Our summer was very warm and dry, and the plant, now about five years old, cramped in a small pot, which may have something to do with it. I send you this account of the plant trusting it may be interesting to Mr. Hemsley and others who have studied the *Yuccas*, a class of plants most valuable for garden decoration, and particularly to English cultivators, nearly all of them being quite hardy in that country. Only four kinds, viz., *Y. filamentosa*, *Y. stricta* (Carrière), *Y. flaccida*, and *Y. angustifolia*, will stand the cold winters of New England.

Boston, Mass.

C. M. HOVEY.

VEGETATION IN FEBRUARY*.

THE weather during the month of February was in general very pleasant, and drier than it had been during the four previous months. Owing to this comparatively dry state of the ground, much outdoor work has been accomplished. During the month, the thermometer was seven times at or below the freezing point, indicating collectively 36°, while the united February frosts during the last twenty-three years amounted to 1492°. The highest markings were during 1855, when 220° were registered, and the fewest during 1869, when 6° only were recorded. Up to February 21 this year only 4° were noticed,

* Read by Mr. M'NAB before the Botanical Society of Edinburgh on March 5.

but since that date frost continued to the end. The lowest markings were on the 8th, 20th, 22nd, 26th, 27th, and 28th, when 31°, 30°, 24°, 28°, 20°, and 24° were registered respectively, while the highest markings were on the 2nd, 7th, 9th, 15th, 18th, and 34th, indicating 39°, 44°, 40°, 41°, 38°, and 40°. This comparative mild state of the weather has brought forward vegetation which had been so long kept back by the excessive moisture of the previous months, as will be seen by the annexed list of spring-flowering plants. It contains the names of the selected species fixed on for annually recording their dates of blooming.

	1877	1876
<i>Eranthis hyemalis</i>	Feb. 1	Jan. 26
<i>Rhododendron atrovirens</i>	" 2	" 25
<i>Lencojum vernum</i>	" 2	" 18
<i>Galanthus nivalis</i>	" 4	" 16
<i>Crocus susianus</i>	" 4	" 20
<i>Scilla præcox</i>	" 6	Feb. 16
<i>Galanthus plicatus</i>	" 6	Jan. 29
<i>Crocus vernus</i> and vars.	" 9	" 28
<i>Nordmannia cordifolia</i>	" 10	Feb. 16
<i>Daphne Mezereum</i>	" 13	Jan. 26
<i>Sisyrinchium grandiflorum album</i>	" 13	Feb. 17
<i>Scilla sibirica</i>	" 14	" 20
<i>Scilla bifolia</i>	" 14	" 24
<i>Sisyrinchium grandiflorum</i>	" 15	" 20
<i>Bulbocodium vernum</i>	" 16	" 16
<i>Iberis gibraltaria</i>	" 17	" 21
<i>Dondia Epipactis</i>	" 20	" 11
<i>Tussilago alba</i>	" 21	Mar. 8
<i>Rhododendron Nobleanum</i>	" 23	Feb. 10
<i>Aubrieta grandiflora</i>	" 24	" 17
<i>Tussilago nivea</i>	" 26	Mar. 18

On the 28th of February, notwithstanding a slight fall of snow and a hard, frozen surface, about fifty species of plants were counted in flower on the rock garden, the most interesting at that time being *Rhododendron præcox superbum*, *Erica carnea*, *E. c. alba*, *Daphne Mezereum*, *Andromeda floribunda*, *Primula denticulata*, *P. vulgaris rubra*, *Corydalis angustifolia*, *Iberis gibraltaria*, *Crocus Imperati*, *C. nivalis*, and *C. susianus*, *Lencojum vernum*, *Galanthus plicatus*, *Dondia Epipactis*, and *Helleborus colchicus*, with seven other varieties. The frost of the 28th had partially injured some of the blooms of the more tender species, while it had the desirable effect of destroying slugs and other surface-inhabiting vermin.

LILY BULBS.

ON looking over "F. W. B.'s" interesting articles on this subject, I find it stated at page 135 (not by him) that *Lilium tigrinum* is a perennial, and that *L. philadelphicum* is an annual; but I fail to see that there are any proofs given for saying so. *L. tigrinum* is one of those which I had distinctly in mind when I said (see p. 175):—"The origin of a Lily bulb is a germ or seed-bud. Nature causes this to vegetate and grow the first year, to bloom the second year, and then it dies—leaves, stem, scales, and roots all perish." In saying this, it may be seen that I had no indications whatever of *L. tigrinum* or *L. philadelphicum* being either annual or perennial. *Lilium philadelphicum* has been described not only as an annual, but as being of a rhizomatose character. "F. W. B.," however, tells us that after examining some fifty or hundred roots, he saw in them no traces of rhizomatose growth; and as I accept what he says, and his drawing of the bulb, as authority, I of course keep this Lily in the same category with *L. tigrinum*. There are also *L. bulbiferum*, *L. croceum*, *L. davuricum*, *L. Martagon*, and others, which are described as perennials, but, in like manner, I see no reason for removing them from the class of biennials. Coming now to the true rhizomatose class, at page 156 I find *L. canadense* and *L. superbum* described not only as rhizomatose, but also as perennials. The drawings show the rhizomatose character distinctly. There are many plants besides this class of Lilies that present subterranean stems, but they all creep in the same manner, obliquely or horizontally, under the surface of the soil, and vegetate at their most advanced point, whilst the parent plant itself gradually decays and dies. This mode of existence in subterranean stems or root-stocks is well exemplified in the drawings of the bulbs. The flowering bulb of the year sends out from its base a rhizome or root-stock, which bears at once scales or modified leaves and root-fibres, at the point of which, carried with it, a germ or seed-bud grows into a bulb similar to the parent one, and this flowers the following year; the whole term of existence, from the vegetating of the germ or seed-bud until the new bulb has grown, flowered, and died, not exceeding two years. The only difference between this class and the other is that the new bulbs do not form within the old bulbs, but at some distance from them, as clearly shown in the engravings. Why any of these, or of the other class,

can therefore be called annual or perennial, I am at a loss to understand. A biennial I understand to be "a plant which lives but two years; its roots and leaves (scales) are formed the first year, its flowers are produced the next, after bearing which it perishes." This seems to me to be the brief but true history of a Lily bulb; especially of all the Old World species.

At page 115, "F. W. B." says:—"It may be safely said that no Lily bulb blooms twice from the same centre; and although most of the Japan Lilies seem to produce flower-stems from the same bulb (on close examination we find that the flower-stalks spring from new buds formed within the old bulb every season), they are, in fact, new bulbs formed within the parent one, but remain attached to the same base, drawing in part sustenance from the surrounding scales, which are only undeveloped leaves." This is, in principle, so closely allied to my doctrine, that is, the three distinct generations in one bulb, as submitted by me to your readers at p. 175, that there would be no great difficulty in resolving your correspondent's theory and mine into one. There is a difference certainly, but so slight that nine out of every ten might very easily overlook it; the application of the "germ or seed-bud" doctrine being, in fact, the only real difference between us. The seed-bud, in October, though so minute as not to be perceptible to the naked eye, hides under its very delicate envelope the source of those brilliant ornaments of Nature which every year witness the birth and death. The seed-bud is, in fact, the cradle of the young plant. This organ alone is capable of reproducing a new individual, which may vary slightly as in the human family. The function of the parent is to nourish, strengthen, and increase its growth, until it is able to rank with others of its own species. It may be said, in fact, that a Lily is all buds; there is scarcely any part that does not produce them—the roots, the scales, the stems, the leaves even, may accidentally give birth to adventitious buds; for Nature never loses sight of the phenomenon essential to organic life—namely, the production of new beings. But these adventitious buds—though they present themselves without any order, and the exact spot where they may present themselves cannot be foreseen—seldom or never present themselves on or near a healthy-growing new bulb; as the new bulb absorbs all nutriment from around it for its own nourishment. In considering the nature of flowering bulbs, it is absolutely necessary to ignore entirely, for the time being, all common or uncommon offshoots emanating from the roots or stems, as they are simply Nature's method of multiplying the species, and not of continuing the race of any particular bulb.

In studying these matters, the terms "seed-bud" and "leaf-bud" have sometimes been confounded; but they differ very much, and more particularly in this, that the leaf-bud propagates the individual as well as the species, while the seed-bud continues the species, but not necessarily the individual. This would seem to direct our attention to a point of some importance to Lily cultivators. Some time ago a difficulty arose about settling the nomenclature of certain varieties of *Lilium speciosum*. It was urged that we had not sufficient evidence as to the constancy of particular forms—that we had no security that the bulb, which this season produces flowers of any particular colour and form, will in the forthcoming season produce the same, especially if grown under different conditions. Now this is just what I have said about new individuals varying slightly; for if we consider that all Lilies emanate from germs or seed-buds, and that, while the seed-bud continues the species, it does not necessarily continue any individual variety, we need not be much surprised that varieties should sometimes vary among themselves, or that an individual variety should now and then itself vary, when a new seed-bud takes the place of the former one, and forms a new and distinct succession bulb. I simply venture to throw out the above hints for the consideration of Lily growers and shall be pleased to be the means of eliciting some account of their experience in the pages of THE GARDEN.

DUNEDIN.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

What is a Hybrid Primrose?—This is a designation given for the sake of convenience to a race of Primroses intermediate in character between the scapeless Primrose and the ordinary Polyanthus, with its erect stem surmounted by a truss of flowers. They display this intermediate character by, first of all, throwing up early in winter a number of flowers on long stems, just as the common Primrose does. Later on, there arises up from amongst this tuft of blossoms, but quite distinct from it, a stiff, erect, Polyanthus stem, bearing a truss of flowers in the ordinary manner. Quite a pyramid of flowers is thus obtained—a most desirable result where Primroses are employed for bedding purposes in spring.—D.

Saxifraga oppositifolia maxima.—This is not the same as *S. oppositifolia pyrenaica*—as might be inferred from the note (see p. 186). The flowers of *S. o. maxima* are much larger than those of *S. o. pyrenaica*.—R.

THE FRUIT GARDEN.

ORANGE CULTURE IN FLORIDA.

I HAVE just returned from my Orange grove in Florida, some account of which may not, perhaps, prove uninteresting. Ten years ago Orange groves could be almost counted upon one's fingers; now they may be found in numerous localities in Florida, some of them very successful, while others have failed from want of the proper exposure and soil. The true Orange soil is not found in every place, and the only position secure from frost is the south-eastern side of a large extent of water. Thus, during the extreme cold of last December, the thermometer went down to 15° Fahrenheit on the west side of the river opposite my grove, and fruit was frozen and young trees destroyed. This also happened 100 miles south of me, while at my grove the thermometer did not fall below 31°, and neither fruit nor trees were in the least injured. This is attributable solely to the fact that my grove lies on the south-east of a long stretch of the St. John's River, and receives the air tempered by the radiation at night from the water heated by a warm sun during the day. A grove that has safely endured such unprecedented cold, and in which the growth and bearing of the trees show that it has the true Orange soil, has a definite money value. The maximum produce of an Orange tree of some age is from 5000 to 7000. This, however, is a rare crop, and 1000 per tree for a grove ten years old is considered to be a successful result, 100 trees planted upon an acre thus producing 100,000 Oranges per acre. I sold my crop this winter at the rate of 2½ cents per Orange, the purchaser picking the fruit. A commoner rate is 2 cents each, and this would give an annual income of £400 per acre. Reduce the bearing one-half and the price one-half, and you have £100 per acre, which is certainly satisfactory. Under proper care and greater age, the produce will be increased. One of my trees ten years old produced over 1000 fruit, and a few years more age will doubtless double its crop. The most experienced men who deal largely in foreign fruit hold a very decided opinion that the price of Florida Oranges can never go very low, their quality being so superior that they bring £2 8s. per barrel, while the West Indian or Mediterranean Oranges realise only 12s. per barrel. They have, however, hitherto been so few that they have reached only a few localities, but they are now being more extensively distributed, and have met with such general appreciation that both the consumption and the price have largely increased. The modes of packing are so much improved, and the express companies at the north have learned so well how to take care of them that they are sent over the whole country in the most severe weather with very little loss. I have no doubt that we shall soon ship them largely to England. It is certainly as practicable as for Sicily to send Oranges to America. I am frequently asked why it is that the Florida Orange is so superior to the tropical ones. I think it is owing greatly to the fact that the tropical Orange blooms and bears without cessation during the year, while in Florida there is always more or less frost, and the tree has a distinct period of rest, bearing one crop of fruit annually, and maturing at the same time. Then, again, I have noticed with the Apple that the farther north a certain variety is grown the finer flavoured it is. The same rule may apply to the Orange; the farther north it can be grown with certain limitations the finer will be its quality. In 1869 I introduced the Bahia or Navel Orange, and many of the trees then budded with it are now in bearing. It proves superior to all others, and is being planted largely. I have several hundred of the little Tangerine Orange planted, but although so popular in the Paris market it is not so much appreciated in Florida; I think, however, that when introduced into our northern markets, its peculiar qualities will make it popular. I have a variety from Japan of the Kumquat order the size of a Cherry, with a skin delicate, thin, and not at all pungent, with pulp of a very delicate texture, and possessing a flavour as sweet and spicy as that of a Navel Orange. It can be eaten whole like a Gooseberry. The tree is quite dwarf, and when fruited in a pot may be placed upon the table and the fruits plucked and eaten. It will not grow upon the Lemon or common Orange stock; it only succeeds upon the *Limonia trifoliata*, which is

hardy here, having withstood exposure in the Central Park for two winters. This Cherry Orange is not yet for sale in this country. An Orange grove in Florida is a beautiful object, and, exclusive of its pecuniary value, is a pleasant thing to have. It furnishes a good excuse to leave our snow and cold in the north and look after the picking of the Oranges in a temperature of from 60° to 80°, except on certain occasions when there is a little frost. While lounging under my verandah and listening to the hum of insects, the notes of the mocking bird in the Orange trees, the flight of doves over me, and the tapping of the scarlet-headed woodpecker, I can scarcely realise the fact that my children were coasting and skating at home. Orange trees shade the side of my house and touch the verandah in front, and two Oleanders from 15 ft. to 20 ft. in height overarch the front path. Limes and Shaddocks of large size may also be seen on all sides, and likewise little Tangerine Oranges half hidden among the foliage. A Magnolia grandiflora, 40 ft. high, overshadows the path to my boat-house, and I was obliged to cut down another with a trunk 2 ft. in diameter, because it injured my Orange trees. It is marvellous how far the roots of Magnolia trees will travel. One would nearly overrun an acre. Fig trees grow luxuriantly, and in one corner of a field is a live Oak grove (*Quercus virens*), the trees composing which are 75 ft. in height, and filled with long streamers of melancholy Moss.

The beauty of the St. John's River is scarcely known to the distant world. It is navigable 300 miles from its mouth, often broadening into lakes, and its waters, which flow north from the Everglades are clear and fresh until they meet the tides from the ocean. Innumerable branches, creeks, and rivers jut out from the river, some running 50 miles into the interior, and navigable by steamboats, while others are narrow and shaded by overhanging trees, which are reflected far down into the mirror-like water below. There are few hills in Florida, but its Amazon-like waters make up for their absence. Blue Spring is a place I once owned, which rises gradually from the St. John's River for a quarter of a mile, (until it reaches a precipitous bank overhanging a sulphur spring which rises the size of a barrel through 10 ft. of superincumbent water), and forms a stream so clear that fish 10 ft. below can be plainly seen. With proper railroad communications Florida can be reached in two days from New York.

Flushing, New York.

SAM'L. B. PARSONS.

INSIDE AND OUTSIDE VINE BORDERS.

I SHALL not venture to assert that Vine roots have an "inherent tendency to travel towards the south," as Mr. Grieve states (see p. 197), but if I have one decided opinion more than another upon (grape growing, it is that the roots will go outside in preference to going inside if they can get out, and I do not think it matters whether the direction is south, east, or west. This is one of those mysteries about which we are at present completely in the dark. I never tried a Vinery on a north aspect, but I believe the roots would travel north under such circumstances rather than remain inside. I have an impression, also, that they multiply faster outside than indoors. During the twenty years—pretty equally divided—which I have spent at Dalkeith Park and Wortley, my experience has been uniform with regard to inside borders. All the Vineries 200 ft. in length at Wortley are planted inside—some entirely so—but in most of them the Vine roots can go both ways; and where this is the case I believe the whole of the inside roots might be cut clean away without any serious detriment to the Vines. Yet all the Vines were planted inside, and the roots were turned in when planted, and every inducement offered them to remain inside, but without avail. To convince myself thoroughly on the subject, I removed the whole of one inside border, up to the front pipes, and found comparatively few roots, and some of these had turned round with a sweeping bend, and gone out between the arches in the front wall. I brought all inside again that I could get hold of, and now, after four years, I can put the spade in several feet away from the back wall to find no roots, while outside they are, I believe, under the walk 20 ft. away nearly, and the whole of the outside border is one mass of roots up to the surface, and it is just the same with our other Vineries. It is a significant fact that in the case of the Vinery in which the inside border was removed and replaced, the Vines scarcely showed any signs of having received a check, but bore fruit and grew as usual. There is only one Vinery in the place in which

we have succeeded in filling the inside border with roots, and in this they cannot get out. The Vines, too, are planted on a ridge in the centre of the house, and one-half of the tops are trained down the rafters towards the front or south, and the others are trained up to the top. My opinion is that an outside border is just about as good as an inside one, to say the least about it, if it be protected with a little fermenting material, and the labour connected with the management of inside and outside borders is about equal. In our case the labour of watering the inside borders, &c., exceeds that bestowed upon the outside generally. To those who have doubts I would say, have your borders either inside or outside, but not both; and to insure filling the former with roots plant the Vines along the centre of the house or against the back wall, and train them down the rafters instead of up.

J. SIMPSON.

Wortley.

THE SEASON AND THE FRUIT CROPS.

WINTER has come at last in the shape of a heavy fall of snow, which lasted from early morning till noon. The northerly and north-easterly winds were sharp and keen, and, altogether the fall of snow and of temperature will no doubt arrest the opening flowers of fruit trees for a time, and perhaps save the crop. Pears are on the move, Peaches decidedly swelling, and Apricots open in some localities, and just on the eve of opening in all. In fact, the fruit crop hangs suspended, as it were, on the weather of the next few weeks; be that what it may, it would be wise to apply all protecting expedients as soon as possible, for even the young blossom-buds that have hardly begun to open are already full of crude sap or quite swollen out with water; and, practically, it matters little whether they have absorbed fluid from the roots, or through their bud-coats (as was at one time held to be possible, but is now generally decided); one thing, however, is certain, viz., that moisture is present and in excess, and that such excess is a source of danger to the fruit-buds. The danger is twofold—the moisture assists the buds to open before the proper time, and it makes them more tender; for both reasons the buds ought to be provided with protection earlier and to a greater extent than usual. The partial shade of protecting materials is also as useful at this early season of the year as their heat-conserving powers, for the sun has often a more fatal influence on vegetation in the early spring than frost. The latter can do but little harm alone, but let the sun work with it to open the buds, and then the frost will most assuredly kill them. By partially shading the blossoms during the glimpses of sunshine, we keep them closed the longer, and closed blossoms are the best possible protection to the tender nectaries or ovaries against cold.

Flimsy protectors in motion are often more potent in their bud-preserving powers than denser ones at rest, the motion charging and breaking, as it were, the stinging lines of cold, and moving them about so rapidly that they cannot get sufficient rest for their killing work. It is the mobility of textile fabrics, whether nettings of wool or string, &c., that renders them of such service for protecting purposes. Again, protect the top of the wall, and its face and bottom are well-nigh safe; it is the radiation into the open sky, when there are no clouds to return any of the heat poured into vacant space, that chills the life out of fruit-blossoms. Shut that open door by erecting a coping, or by some other means, to prevent the loss of heat, and the blooms will in all probability be saved. But as the late mild and wet weather has made fruit-blossoms abnormally tender, not a day should now be lost before all efficient expedients for their protection is resorted to.

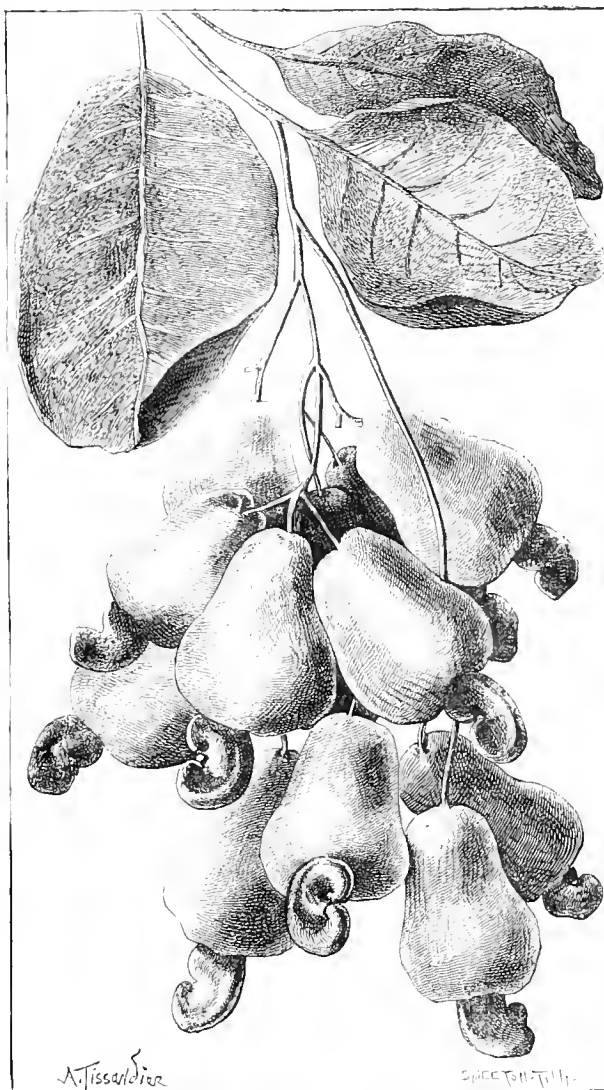

D. T. FISH.

Varieties of Melons.—Mr. Hinds (see p. 193) truly says, that "we have far too many varieties of Melons, or rather names." The remedy for this evil lies to a great extent with ourselves. A friend of mine, an excellent fruit grower, grows but one kind of Melon, the seed of which he has saved for about twenty years, and I have never seen finer crops of good fruit than those which he produces. My advice to the inexperienced is, when they prove any particular sort to be good in constitution, bearing, flavour, and appearance, to keep to it, and not be led away by the bewildering array of names in catalogues. Mr. Hinds refers to Meredith's Hybrid Cashmere and Trentham Hybrid, which were, so far as I could judge, very much alike. With regard to the former, no finer-flavoured or handsomer fruit was ever grown, and as I happen to have a few seeds taken from one of Mr. Meredith's prize fruits at the Royal Horticultural Society, I will send Mr. Hinds a few, but cannot guarantee them vegetating, as they are from fourteen to sixteen years old. I have also seeds of Trentham Hybrid saved from a true stock, of which he shall have a few, and if he succeeds in growing them, I hope that he will give us his opinion of their merits at the end of the season.—J. E.

THE CASHEW NUT.

(ANACARDIUM OCCIDENTALE).

THIS Nut tree is much cultivated in the West Indies and other tropical countries where the roasted Nuts or kernels are used as food. It forms a large, spreading tree, not unlike a Walnut in general appearance, but with more bluntly-oblong leaves, the agreeably-odorous, rosy-tinted flowers which precede the fruits being produced in panicles at the tips of the young branches. The fruits are borne in Grape-like-drooping clusters, as shown in the accompanying engraving. The Nuts themselves are rarely larger than a Kidney Bean, each being borne singly at the apex of a large, Pear-like receptacle. The stem of the tree when pierced exudes a milky juice, which dries hard and of a dark colour, and which may be used as a varnish or gum. The shell of the Nut contains an acrid oil, which often causes severe excoriation of the lips and gums, if cracking the Nut in the mouth be attempted. Even the kernels are acrid until after they have been roasted, when they become not only wholesome but peculiarly agreeable in flavour. The roasting has to be carefully conducted, as the acridity of the volatile oil given off in the process is so great that it is apt to produce inflammation in the face. The gummy product of this Anacardium is used by bookbinders in South America, who wash their books with it, in order to keep off moths and ants; and the essential oil of the fruits is likewise applied to the floors of houses in India to ward off the ravages of white ants, which throughout the tropics are so numerous and destructive. B.

The Cashew Nut (*Anacardium occidentale*).

STRAWBERRY CULTURE.

A LABOURER in Yorkshire having a garden about 25 yards long by 12 yards wide, has for several years cultivated Strawberries for sale as follows:—He commenced by making two beds across the middle of his garden, each bed being 4 ft. wide. The variety planted was Rivers' Eliza, a free-bearing kind which appears to suit his soil, which is of a light character. On the outer sides of these two beds, he planted three rows of Early Ashleaf Potatoes which he lifted about the end of June. The land thus cleared early was raked level, so that the Strawberry runners could overrun it and establish themselves and produce a crop the following season. Next year he planted Early Ashleaf Potatoes as before up to the Strawberry runners produced the previous summer; lifted the Potatoes at the end of June, and levelled the land again for runners. He called this system "a travelling Strawberry bed," a designation which it well deserved, for the whole garden soon became covered with Strawberry plants. About the third year the two beds first planted became exhausted, and the plants were dug in along with a good portion of manure. In the spring a crop of Kidney Potatoes was taken off the land thus bared, and Strawberry runners allowed to

establish themselves. Each succeeding year this practise was followed. Having heard that this man had large quantities of Strawberries for sale, I was induced to pay him a visit. I found his fruit large and fine, and he had good sale for it both for table and preserving. His garden, he said, did not give him much trouble, and at the end of the season it had produced so much fruit that he sold £7 worth. There are many persons who have gardens, the soil of which is so light that all attempts to cultivate Strawberries in them have been unsuccessful. Where clay cannot readily be obtained, road scrapings can generally be had for nothing; in preparing a plot of land, let a good portion of these be incorporated with the soil and also some good manure; tread the beds down firmly and then plant the runners about 15 in. apart, and a fair crop may be produced the first year. Strawberry runners procured from a distance always do better than those from one's own garden. H. T.

GOOSEBERRY FUNGUS.

THIS is a species of *Æcidium* (*Æ. cancellatum*) and consists of small, membranous sacs or protuberances, which are found parasitic on the leaves, bark, and fruit of several plants, such as the Fir, Violet, Barberry, Hawthorn, Mint, Primrose, and Nettle. The membrane forming the sac has received the name of Peridium. It pierces the bark or epidermis of the leaves, and encloses very minute dust, like seeds or sporules, which are ultimately discharged by an opening in its side or summit. In consequence of the seeds being contained in a membrane, the genus has been referred to a division of fungi which has been denominated *Angiocarpi*. There are upwards of thirty known species of the genus, and they receive their names from the plants on which they are found. Link has divided this genus into three subgenera, the *Æcidium* properly so called, the *Ræstelia*, and *Peridium*. The *Æ. cancellatum* belongs to the second of these divisions; it is often found on the leaves of Pear trees. To the third division belongs the *Æ. Pini*, remarkable for being the largest species, and for growing not upon the leaves but upon the bark of the Pine tree; they vary in colour. The species that grow on the Gooseberry and Barberry leaves are red, that found on the Scotch Fir is yellow, and that on the Meadow Rue bright orange. The *Æcidia* cause considerable deformities in the plants on which they grow, and some of them are decidedly injurious and poisonous. The Gooseberry *Æcidium* frequently destroys the young fruit; the species found on the Barberry has been stated, though perhaps erroneously, to be hurtful to corn growing near it. My experience with regard to the Gooseberry fungus is as follows:—Some years ago about one-third of the fruit in a plantation became blotched very much with this fungus. I gave the ground amongst the bushes a liberal dressing with

lime in the autumn, and syringing them over with a compound consisting of alum, 1 drm.; Tobacco essence, 2 drms.; flowers of sulphur, $\frac{1}{2}$ oz.; common salt, $\frac{3}{4}$ oz.; all mixed in 3 gallons of rain water. This was done twice before the expanding of the leaf, and again as soon as the fruit appeared to be fairly set. The first application destroyed the mycelium in the soil, and the syringing cleared the bark of its sporules, and my Gooseberry bushes were left free from all trace of fungus.

Rawdon, Leeds.

J. GRAHAM.

TREES AND SHRUBS.

THE PRIVETS.

THESE form a group of evergreen and sub-evergreen shrubs, distributed over a wide area in Europe and several parts of Asia, chiefly in the colder or temperate regions. Most of the known species are sufficiently hardy for cultivation in open shrubby borders, and even the tenderest succeed perfectly when planted against a wall. All the sorts are valued for their beautiful, and more or less fragrant flowers, which are generally produced in great profusion. They all thrive well in sheltered situations near the sea, and are among the few evergreens that grow well exposed to the smoke and dust of towns. One or two of the hardiest of the species are extensively planted as garden-hedges or screens, for which, as they may be trimmed or clipped into almost any shape, they are peculiarly well adapted. The following is a selection of the most desirable species and varieties:—

Common Privet (*Ligustrum vulgare*).—This is a native of Britain and several of the countries of continental Europe. It forms a bush of from 6 ft. to 12 ft. in height, with abundance of slender, wiry branches. Though usually classed as a sub-evergreen shrub, it is found to retain its foliage through the winter in warm, sheltered situations—that of some plants being more persistent than that of others under any circumstances. The flowers, which are sweet-scented, and borne in terminal panicles, appear about the end of July, and are in most seasons abundant enough to render the plant very attractive. Not the least interesting feature of this species is its beautiful clusters of dark purple berries, which ripen in November, and hang on the branches during the greater part of the winter. It is scarcely necessary to say that the Common Privet is seldom planted as a specimen in ornamental shrubberies, but is one of the most popular of our garden hedge plants; as such it is met with in every district of the country, growing freely in almost every variety of soil, requiring little labour to keep it close and neat, and, moreover, so hardy as to be unaffected by the severest frosts. As it thrives well under the shade and drip of trees, it is now largely planted in woods as an undergrowth or shelter for game. There are several varieties of it, of which the undermentioned are the most useful for decorative planting;—*L. v. fructu-luteum* or *xanthocarpum*.—This is somewhat denser in its habit than the type, but of equally free growth; it has a pretty effect in autumn and winter when covered with bright golden fruit, which contrasts well with the dark foliage. *L. v. pendulum*.—This variety has long weeping branches, and when grafted as a standard on a stem 4 ft. or 5 ft. high, forms an elegant specimen for a small lawn, or in any other situation where it can develop its peculiar character without obstruction from other shrubs. *L. v. variegatum*.—The leaves of this form are prettily blotched with bright gold. It is scarcely so robust as the parent, of which it is a sport, but it grows quite as freely. The variegation is always most brilliant, as well as most constant, when it is planted in poor sandy soil, and in an aspect fully exposed to the sun. *L. v. buxifolium*.—A very distinct variety, differing from the species in its broader and more decidedly evergreen leaves. It is a handsome bush for a shrubbery, and is particularly desirable as an ornamental hedge plant.

The Leather-leaved Privet (*L. coriaceum*).—This dwarf-growing evergreen species is indigenous to Japan, where it is reported as occurring in mountainous districts in considerable abundance, and as being largely cultivated as an ornamental shrub. It was first introduced into British gardens in 1861. In its native habitats it is rarely found higher than from 3 ft. to 4 ft., forming a densely-branched bush, abundantly furnished with dark, glossy green leaves of a thick leathery texture, and of a more or less orbicular shape. The flowers, which are of a greenish-white colour, are even at their best not very conspicuous. Though the points of the young shoots are sometimes slightly injured in severe seasons, particularly when the plant is growing in damp or much exposed situations, this fine plant may be fairly classed among our hardy shrubs, and its dwarf, bushy habit, and dark shining foliage, commend it to the notice of

planters who require low-growing evergreens for the margins of borders, or for winter bedding in the flower garden, where it contrasts admirably with most other shrubs generally employed for that purpose, and particularly with those having variegated foliage.

The Japan Privet (*L. japonicum*).—This, as its name implies, is indigenous to Japan, where it is said to be a favourite flowering shrub in gardens, and whence it was first sent to Britain in 1846. It is a spreading evergreen bush which grows about 10 ft. high; its leaves are large, broadly ovate, sharply pointed, and dark glossy green. The flowers begin to expand about the end of June, are pure white, and delicately fragrant; they are borne on large, upright panicles from the points of the shoots, and when in perfection are very effective. This handsome species succeeds tolerably well in the open shrubby border, where the soil is dry and the situation sheltered; but even under the most favourable circumstances it is subject to injury from severe frosts; planted against a wall, however, it is rarely injured in the slightest degree, growing freely, and producing its showy blossoms season after season in great profusion. The following varieties of it have prettily variegated leaves, and are popular as wall shrubs. They develop their colours best when planted in a sunny aspect, and in a rich but dry soil:—*L. j. aureum marginatum*.—The leaves of this are edged with bright gold. *L. j. argenteum marginatum*.—This differs only from the preceding in the colour of its variegation, which is pure white.

Shining-leaved Privet (*L. lucidum*).—This very distinct species was first introduced into British gardens from China in 1794. It is a broad-growing, bushy evergreen of about 10 ft. high, with a somewhat stronger constitution than that of *L. japonicum*. The leaves are smaller than those of that species, ovate-lanceolate, pointed, and of a dark glossy green colour. The flowers, which are pure white and sweet-scented, are borne in upright panicles from the points of the branches; they expand in September and October. Though this shrub succeeds tolerably well in the open shrubby border, forming, in moderately-sheltered situations, a handsome bush, it is always found to grow and flower best on a sunny wall; it likes a rich soil, not too stiff, but it must be well drained. The following variety is a favourite with planters of ornamental wall shrubs, viz.:—*L. l. variegatum*, the leaves of which are blotched or margined with gold. It is scarcely so robust as the parent, but grows quite as freely.

The Indian Privet (*L. nepalense*), also known under the name of *L. spicatum*, is a sub-evergreen species, indigenous to mountainous districts in Nepal, where it forms, at considerable elevations, a densely-branched bush of from 8 ft. to 10 ft. in height. It has been cultivated in British gardens ever since 1823. Its leaves are elliptic, acute, of a bright glossy green colour, the under surface being more or less thickly covered with minute hairs. The flowers, which are in spikes, and pure white, are fragrant, and in perfection in June and July. This species, which is distinct, is probably the most ornamental of the genus, so far, at least, as the flowers are concerned, but it is, unfortunately, too tender in most districts for cultivation in open borders; it is, however, admirably suited for planting against a wall, where, if moderately sheltered and in dry soil, it grows and flowers freely, and rarely suffers from frost. In mild seasons, when so sheltered, it is nearly, if not altogether, evergreen.—“The Gardener.”

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Moving Large Trees.—In Paris at present, instead of planting young Plane trees as of old on newly-formed boulevards, large and well-furnished trees are planted. Thus the newly-formed Boulevard Henry IV. is furnished throughout with well-grown plants, with stems nearly 1 ft. in diameter, and nearly 30 ft. high. It will be interesting to notice how they will pass through the summer.—V.

The Monarch Oak.—This, the largest Oak in Herefordshire, was sold the other day by auction. The reason for cutting down this king of the forest was because it has been three times struck by lightning within the last seven years, but though these repeated attacks have shattered a great part of its top, it still contains upwards of 1000 cubic ft. of timber, and its girth is 66 ft. With this tree two smaller Oaks were included (one of them a dead tree), and the three together realized the reserve price of £200.

Ghent Azaleas as Underwood.—I would suggest to those about to plant evergreen underwood to intermix, especially with Rhododendrons, the yellow Ghent Azalea. There are many colours of this fine hardy flowering shrub, but the yellow is the most robust, and makes the best rabbit-proof covert next to the Rhododendron. Being sweet-scented, moreover, gives it an advantage, and for coverts, in connection with dressed grounds, a decided advantage. The yellow-flowered, black-berried *Berberis Aquifolium*, too, is a better rabbit-proof covert than the Laurel, which with us is more eaten by rabbits than any other evergreen. Evergreens should never be planted in great sweeping masses, but should be divided or sub-divided by deciduous plants, and for this purpose the above Azalea is well adapted.—HENRY KNIGHT, in *Field*.

HARDY FLOWERS IN LONDON GARDENS.

OWING to the continuance of cold weather but few of these are in flower which were not noticed last week. Daffodils are everywhere very showy, the common double yellow, the white Paper, and the double Roman being especially attractive in most places. The old-fashioned double yellow Wallflower is also just now very showy at Mr. Ware's, where may likewise be seen *Saxifraga oppositifolia major*, bearing a quantity of deep rosy-purple flowers. Snowdrops and Dog's-tooth Violets are still effective, as are also *Iris reticulata* and its variety called *Krelagei*. *Arabis blepharophylla* is bearing clusters of deep

Common Violet (*Viola odorata*).

rosy flowers in abundance. This plant, though introduced by Douglas in 1833, is not so common as it ought to be; it, however, well deserves culture both in pots and in the open ground, where a supply of cut flowers is needed in winter and early spring. *Primula erosa* and *P. denticulata* are also just now in good condition in London nurseries, and the Spring Snowflake (*Leucojum vernum*) is still, in warm, well-drained beds, bearing multitudes of drooping, Snowdrop-like flowers. At Barr's grounds at Tooting Primroses are still attractive, as are also Squills and Hepaticas, and under trees *Aubrietia grandiflora* is producing thousands of small, purple, starlike blossoms. The Snake's-head Iris (*I. tuberosa*) is throwing up strong spikes of dull-coloured blossoms at Tooting, where may also be found double white, red, and pink Daisies, and

Mossy Saxifrage (*Saxifraga hypnoides*).

Dwarf Phlox (*P. setacea*).

Cyclamen Atkinsi, flowering freely. *Erica mediterranea rubra* is still very pretty at Parker's, as are also *Ficarias* and *Bulbocodium vernum*. A variety of *Anemone*, called by Mr. Parker *Gloire de Nancy*, is bearing large, blue, Poppy-like blossoms in abundance, and *Vinca major variegata* and *V. minor* are just coming finely into flower. At Kew *Arabis alpina albida* is thickly covered with pure white Alyssum-like blossoms; and *Iberis Garreuxiana*, growing in the form of large tufts, is producing white and brown flowers from every point. *Anemone pavonina* and *A. hortensis* are also still in good condition at Kew, where the Spring *Adonis* (*A. vernalis*) is likewise throwing up large, yellow, Tulip-like blossoms. S.

PARK ROADS.

THE quality and permanency of a road depend to a great extent upon the way in which it is made at first; but we are afraid that road-making is almost a lost or little understood art on gentlemen's estates. Agents, gardeners, and others may often succeed after much labour and experience in constructing a tolerably good "permanent way," but it is not every one who understands how to set about it at the beginning, or the first principles of road-making. Let us take an example or two of many that could be furnished. A gentleman who had spent thousands of pounds on his parks and estates, among other improvements, laid out some miles of new roads. These were cut out in the ordinary way, and then filled in higgledy-piggledy 5 in. or 6 in. deep with water-worn gravel, fine and rough together, which never settled into a crust, but worked constantly to the surface, leaving the road in a continually uncomfortable state for both wheel and foot traffic. In the other case the road-metal used was of the wrong description, being too soft, and it was laid upon the road before the bottom had settled uniformly, which resulted in the road becoming uneven and full of hollows which had to be filled up afterwards, making the surface appear if anything more patchy and uneven than it did before. Eventually the roads were hacked up again after a few years and macadamized properly under the superintendence of one who understood the work, and from that day to this—nigh twenty years now—they have required no attention save occasional hoeing at the sides and sweeping with a broom. After the heaviest rains or prolonged wet weather they are soon dry and comfortable, the water disappearing from the surface immediately, and at ordinary times they are as smooth as a pavement. The reason why such roads are so often ill-made is because the work is usually entrusted to ordinary labourers, who have not the slightest notion of road-making, more than that it consists in covering the ground with stones laid on anyhow. The workman is not, however, always to blame. Directions are sometimes given on the subject of such a kind, it is to be feared, as to deter gentlemen from attempting the task of road-making altogether, or at least from attempting more than half measures. Since these remarks were begun we have noticed a chapter on road-making in a contemporary, in which we are informed, among other items, that the principal thing in the formation of roads is "to have a good solid foundation," which foundation is to consist, even where the traffic is light, of rough stones or slag run together with chalk or some other binding material, and is to be covered with a considerable depth of broken or smaller stones on the top, the whole to be 8 in. or 12 in. deep. This is neither more nor less than Telford's system, which is the most expensive of any. Digging out the soil and laying solid foundations 8 in. deep for walks and carriage drives where the "traffic is light," is quite unnecessary work, and a plan seldom adopted under such circumstances. Indeed, many engineers maintain that "solid foundations" made of large stones, are just as useless, if not as great an evil, in ordinary roads as stone sleepers were found to be on railways. At all events, such solid foundations are not necessary in park roads, and this the great road-maker—Macadam—demonstrated long ago. By his system roads can be made both cheaply and well, if his instructions be carried out as they should be, and perhaps we could not do better than quote them here. He says:—"For the foundation of a road it is not necessary to lay a substratum of large stones, pavement, &c., as it is a matter of indifference whether the substratum be hard or soft: and if any preference be due, it is to the latter. The metal for roads must consist of broken stones (granite, flint, or whinstone, is by far the best); these must in no cases exceed 6 oz. each in weight, and stones of from 1 oz. to 2 oz. are all to be preferred. The large stones in the road are to be loosened and removed to the side, where they are to be broken into pieces of the regulation weight; and the road is then to be smoothed with a rake, so that the earth may settle down into the holes from which the large stones were removed; the broken metal is then to be carefully spread over it, and as this operation is of great importance to the future quality of the road, the metal is not to be laid on in shovelfuls to the requisite depth, but to be scattered in shovelful after shovelful till a depth of from

Rollisson's Telegraph Cucumber.—I find the true strain of this Cucumber to be most productive. Plants of it in a house that has been in full bearing ever since last November are still producing young fruit in abundance, and where Cucumbers have to be supplied every day in the year, this variety is, without doubt, one of the best in cultivation.—RICHARD NISBET, *Aswarby Park, Folkingham.*

6 in. to 10 in., according to the quality of the road, has been obtained. The road is to have a fall, from the middle to the sides, of about 1 ft. in 60 ft., and ditches are to be dug on the field side of the fences to a depth of a few inches below the level of the road." Now Macadam, whose system has superseded nearly every other in this and in Continental countries, speaks of ordinary country roads calculated to sustain heavy traffic, and the greatest depth of metal recommended is 10 in. For carriage drives and park roads half that depth is often considered sufficient, and we can state that, if the directions given here be followed out, particularly as regards levelling the bottom of the road and allowing it to settle, and the spreading of metal, 5 in. or 6 in. is sufficient; and for this depth of stones it is not necessary to dig out the road deeply, nor to remove much more than the turf, in fact: this will allow the road to be a little higher in the middle than the ground at the sides, which will permit the water more readily to run off. Macadam's object was not to allow the water to drain through amongst the stones and settle in the bottom to make a puddle of the soft soil beneath, but to make a hard and impermeable crust that would throw the water off at the sides. More depends, it may be said, upon the making of the road than upon the quantity of material used, and the most essential points are a level and well-settled bottom and the regular spread of the stones. Thiu macadamized roads have been made over peat bogs and they stood, and we have seen carriage roads laid with only 4 in. of stones on a loam bottom that had not budged after years of traffic. It may be added that it is not necessary for the whole of the road-metal to be of hard stone, such as whinstone, if it be not easily procured. Soft stones, or even broken bricks will do for the purpose; but these must be laid in the bottom, and the top layer must consist of hard stones, which should be broken small, and the finest saved for spreading on the surface as binding material. Above all, it is essential that the stones should be angular in shape, and for this reason they must be broken. Some use sifted water-worn stones or gravel, but such material shifts under the traffic, and then the crown of the road gives way.

S.

Glazing on Mr. Pearson's Plan.—Having read the remarks on glazing by Mr. Pearson (see p. 184), and also those by "B. S." (see p. 197), I am induced to say that at Willey Park, Broseley, Salop, there were some years ago about 4000 ft. of glass glazed on the plan recommended by Mr. Pearson, and it was found that the breakage through frost was very considerable. The water running down the centre of the squares accumulated under the lower point, where it became frozen and cracked the glass straight up the middle. Perhaps Mr. Stevens will kindly inform us if this still occurs. No difficulty was experienced in cutting the glass to the desired form; the glazier had a piece of thin board the size and shape of the required squares, the board having a narrow piece of wood nailed along one side to fit against the side of the glass, which was cut into long lengths the required width; the board or pattern was then placed on the glass, and the diamond run round the top or bottom as it would have been along the side of a rule.—D. WALKER, *Dunrobin, Tainbridge Wells.*

Peaches and Nectarines.—These are in full bloom here, and the trees are healthy and promising. They are fully a month earlier than usual. We protect them with double fish nets and the Chiswick hexagon net, kept off the wall by means of ordinary Larch poles, and we rarely fail to have a good crop; but the situation is good, with a naturally well-drained soil.—JOHN GARLAND, *Kellerton, Exeter.*

West v. South Aspects for Apricots.—On south aspects Apricots are rapidly opening their blossoms, while those on west aspects have made as yet little progress. In our fickle climate retarding for only a few days is an important point in the case of fruits that bloom at so early a date as the Apricot.—J. G. H.

An Old Pear Tree.—During the late storm a large Pear tree in the orchard of Mr. Robert Hay, Chase Farm, Ambergate, was blown down. Mr. Hay says that when his great-grandfather took possession of the place in 1750, or 127 years ago, it was a much larger tree than when he (Mr. Hay) was born, in 1830; and since then it has lost several large limbs in exceptionally high winds. Mr. Hay believes it to be considerably over 300 years old, and the dimensions taken to-day, as below, will, I think, to some extent bear out his assertions. The tree has been a great favourite with the old gentleman, and last year it bore a large crop of very good fruit. It had two trunks, dividing about 3 ft. from the ground line. The measurements are—Circumference at ground, 9 ft. 6 in.; at 3 ft. above ground, 11 ft.; of largest trunk, 6 ft. above ground, 6 ft. 6 in.; of smaller trunk, 6 ft. above ground, 5 ft. 6 in.; of largest bough, 4 ft. 6 in.; next largest bough, 4 ft.; height from ground to top, 45 ft.—*Derby Mercury.*

PLATE LXV.

ANEMONE FULGENS.

Drawn by H. HYDE.

THE Scarlet Windflower (*Anemone fulgens*—Gay) is a native of the south of France, where it occupies but a very limited area, and that for the most part cultivated land, especially in vineyards. Although it is nearly related to *Anemone stellata* (Lamarek), there appears to be quite sufficient ground for considering it a distinct species, as Gay did when he described it as *A. fulgens*. In fact, the localities in which *A. fulgens* and *A. stellata* are found are far distant from each other, and the seedlings of *A. fulgens*, although very often distinct from their parent, in no way ever revert to *A. stellata*. On the other hand, it seems to be perfectly certain that the plant known as *A. pavonina* is only the double-flowered form of *A. fulgens*, as its roots, leaves, and other characters are perfectly identical with those of *A. fulgens*; and, moreover, it frequently turns up among seedlings of the latter, and is sometimes even intermixed with it in a wild state. As *A. pavonina* yields no seed, and is propagated only by roots, the reason is obvious why it never under cultivation reverts to *A. fulgens*. The Scarlet Windflower may be considered to be perfectly hardy, inasmuch as it has been known to withstand, in the open border, the severest frosts of the last ten or twelve years; it is scarcely, indeed, if ever, injured by mere cold, but stagnant moisture is very detrimental to it. No hardy spring flower with which I am acquainted can compete with it as regards brilliancy of colour, which, when lit up by bright sunshine, becomes perfectly dazzling. In good, well-drained soils it will succeed anywhere, but it thrives best in a rich loam on a northern aspect, and in a somewhat shaded situation. To insure success, it should have a liberal supply of manure incorporated with the soil, which should be mulched with stable manure before frost sets in. Division of the roots is the surest and most rapid way of propagating it, as it is liable to sport if raised from seeds. Seedlings, as a rule, lack the bright colour and the substance of the parent plant, while some will become double, and resemble, more or less exactly, *A. pavonina* as grown in gardens. Roots of this *Anemone* may be transplanted almost all the year round, although the resting time extends only from June to August; but in order to insure early and good flowers, they should be planted as early as possible in the autumn. Some leaves will make their appearance in September or October with a rounded three to five-lobed outline; these will be succeeded in January by finely and deeply-cut leaves, and soon afterwards by flowers. A good bed of well-grown plants of *A. fulgens* in full bloom is a gorgeous sight; but it is not only useful for out-door decoration alone, inasmuch as the cut flowers will be found to expand beautifully in water, and last for a week or more if cut when just coming into bloom and kept in a moderately warm room.

HENRY VILMORIN.

Globularia Alypum.—Of all the *Globularias* I have seen, either in Switzerland or Italy, none is so beautiful as this species. I have met with it at San Remo, growing on dry rocks near the sea-coast, in the month of January, and also still more abundantly in the hill district above Bastia, in Corsica. The flowers are of a rich, deep blue, and growing in tufts in the axils of the branches; their colour when they first expand is strikingly beautiful. Though far from uncommon along the coast-line of the Mediterranean, this species is unknown in Switzerland and Germany, nor does it ever occur, I believe, far from the neighbourhood of the sea. Above Bastia it attains the size of a good-sized shrub. The other species with which I am acquainted are herbaceous or suffruticose in habit. I have seen *G. vulgaris*, *G. indicaulis*, and *G. cordifolia*, but they are none of them to be compared with *G. Alypum*. I gathered a large bunch of its blue flowers on the rocks of the Riviera, between San Remo and Ospedaletti, about the middle of January, 1875.—PETER INCHBALD, *Hovingham Lodge, York.*

An Early Tree.—The famous Horse Chestnut tree in the Tuileries Garden, which has received the name of "Marronnier du 20 Mars," as it was always observed to put forth leaves before any other in the park at about that date, is this year forty days earlier than usual. For some weeks past it has been covered with buds, and on February 9 a ray of warm sun tempted forth its first leaf.

NEW NORTH AMERICAN PLANTS.

(CANBYA AND ARCTOMECON).

CANBYA CANDIDA, a charming little winter annual, of which the annexed is a representation, is one of the discoveries made by the botanical party, consisting of Drs. Palmer and Parry and Mr. Lemmon, which passed last winter in South-east California and adjacent districts. Dr. Parry, who immediately recognized its botanical interest, proposed to dedicate the plant to our

Canbya candida.

common friend and worthy fellow botanist, Mr. William M. Canby, of Wilmington, Delaware; and I have peculiar pleasure in carrying this proposition into effect. The plant is diminutive in size, but of much botanical interest and no small beauty. From the Sagina-like tuft of foliage at the surface of the ground rise a multitude of little peduncles or scapes, each tipped with a bright white flower which lasts for many days; the petals (barely 2 lines long) open at sunrise, and at

Arctomecon californicum.

sunset close over the ovary, and at length permanently over the capsule, into a globular form, which the discoverer likens to a pearl.

The most unexpected anomaly in this Order of a persistent (instead of caducous) corolla is shared by Arctomecon, a native of the same district, as Dr. Parry himself ascertained upon re-discovering that exceedingly rare plant in the spring of the preceding year. There are other Papaveraceous plants which hold their petals for a day or two, notably Sanguinaria, in which they open and close for four or five days before falling; but in these two peculiar genera they become scarious,

remaining permanently in Arctomecon, and up to the full maturity of the capsule in Canbya. The two genera, although closely related, differ in some important points of floral structure as well as in aspect. The most marked difference is in the stigmas, which in Canbya are perfectly sessile, long, entire, and divergent to the utmost, so that their backs are closely applied to the surface of the rounded top of the ovary, directly over the placenta, and the upper or ventral face papillose-stigmatic; while Arctomecon, of which the accompanying is a representation, has a short style, the indistinct lobes of which bear extrorse and two-lobed stigmas, which are alternate with the placenta, and are closely appressed or even partly united in a kind of head. The capsule of the one is membranaceous and dehiscent to the base; of the other, coriaceous and apparently dehiscent only to the middle. The seeds and the stamens are likewise different. The illustration of Arctomecon in "Fremont's Report" exhibits none of these characters, and it led Bentham and Hooker to conjecture that that plant might be only a Papaver, allied to *P. nudicaule*. Dr. Parry's specimens were received in time for a partial reconstruction of the generic character in the "Botany of California"; but the position of the stigmas and the presence of a prominent crest of the seed have not before been noticed.

ASA GRAY.

COMPARATIVE HARDINESS OF HYBRID ARALIAS
IN THE SOUTH OF IRELAND.

TOWARDS the end of last spring I obtained from one of the principal Continental nurserymen a collection of sixteen varieties of these very ornamental-foliaged plants, with the intention of trying how many of them would prove hardy in this mild and moist part of Ireland, and though the winter now coming to a close has been almost everywhere remarkable for its mildness and almost entire absence of any severe frost, still, as these plants have not received any kind of protection and have very decidedly different degrees of hardiness, a few notes, the result of my experience concerning them, may not prove uninteresting. I may state at the outset that all the plants were grafted specimens, and many of them so recently that the top of the stock still remained uncut, and in every case the stock used appeared to be the variety called *A. Schœfferi*, a kind, I suppose, easily raised from seed. The least hardy of all the sixteen varieties is undoubtedly the handsome, large-leaved *A. dactylifolia* (also known under the name *Oreopanax*); this variety, which somewhat resembles in appearance and texture of leaf the foliage of the Rice-paper plant (*A. papyrifera*) should, if wintered in a house, make a handsome object in the centre of a bed in a sub-tropical garden during the summer months. The next least hardy is *A. mexicana* (also known under the name of *Dydimopanax*), a kind which has handsome dark green, five-lobed foliage; this, though it did not suffer so much as the last-named variety, cannot be considered hardy. *A. Thibauti* comes next as regards comparative hardiness, and may almost be considered hardy, as though some young and miniature leaves, which the extreme mildness of the season induced the plant to put forth about Christmas were killed by a pretty sharp frost we had a week ago, the mature leaves are quite uninjured. None of the other thirteen varieties have suffered at all from frost, and only the immature young growth of one of them from the extreme damp of the late autumn before any frost set in. *A. angustifolia* and *A. Cooki* closely resemble one another in shape of leaf and dwarf habit of growth, the first-named seeming a slow-growing and somewhat delicate-habited variety, with foliage of a lighter green and somewhat narrower than that of *A. Cooki*, which is of a dark shade indeed. *A. Knightiaefolia* (a variety saved from seed by M. Makoz, of Liège, who is also the raiser of the varieties *A. Abeli* and *A. angustifolia*), is a narrow-leaved kind, with a white vein down the middle of the leaf; this promises to be distinct and good. *A. Abeli* is a strap-leaved variety, also with a white vein on the midrib, somewhat resembling *A. trifoliata* in shape of leaf. *A. Schœfferi* and *A. quinquefolia* closely resemble one another in foliage, and are both vigorous-growing, handsome sorts, with five-lobed leaves, the lobes being slightly toothed and of rather a lighter shade of green. I am informed that this

variety stood 16° or 17° of frost in the north of Ireland the winter before last without being in the least degree injured thereby. *A. Standishi* is an upright-growing kind, with light green, single-lobed foliage, somewhat resembling that of a *Nerium*. *A. heteromorpha* is a variety with very dark green leaves of a thick, leathery texture, and varying singularly in shape, no two of them being of the same shape; the lobes are fimbriated and have a whitish midrib; this is an exceedingly handsome and distinct variety. *A. Cunninghami* has long, three-lobed foliage, of a thick, leathery consistency, of a dull green colour, but quite distinct in shape. *A. crassifolia spatulata* is perhaps the most uncommon and extraordinary-looking of the whole, having long, curiously-bent and curved, narrow, strap-like foliage of an extremely thick and leathery consistency, with a deep golden midrib down the centre of each leaf, and unevenly toothed on both sides, exactly resembling a saw, altogether a singular-looking plant; it was of this variety that the immature growth was destroyed by the autumnal damp. *A. crassifolia picta* is an exceedingly curiously-marked and ornamental variety, with perfectly straight and much narrower foliage than that of the last-named kind, with a bright yellow stripe down the middle of the leaf, and curiously-coloured spots along the edge, which is also furnished with a few small thorns at intervals, and is entirely untoothed. *A. Hookeri* is an exceedingly quick-growing, vigorous-habited variety, with perfectly straight, strap-like foliage, resembling that of the last-named kind in shape, but longer and broader, and with a distinct and handsome red midrib to the leaf; altogether an exceedingly handsome and distinct variety. *A. trifoliata latifolia*, a quick-growing, vigorous-habited variety, with large, deep green, three-lobed foliage, each lobe being slightly toothed and having a pale yellow vein down the centre. W. E. G.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Vinerias.—If Vines that were started a few weeks ago have broken, they should have a little more warmth given them. In admitting air, be careful that cold draughts are not introduced, or they will interfere greatly with the proper development of the young leaves. A Vinery in the stage just alluded to may be made to be of use for other things besides Vines, as, for instance, Strawberries, a few pots of which may be started in such a house; Potatoes may also be grown in 12-in. pots, which should be drained and half-filled with a mixture of ordinary loam and rotten manure; put one Potato in each, covering it with 1 in. or 2 in. of soil, when growth has progressed, filling the pots up; of French Beans likewise some may be sown, using 10-in. or 12-in. pots, draining, and half-filling them with good soil, putting the Beans in not too thickly, and covering them about 1 in.; these, too, when up and of some size, should have the pots filled with soil. Whatever of this description is grown in a Vinery must not be permitted to interfere in any way with the Vines, as they, of course, should be the first consideration. The Beans are very liable to become infested with red spider; to prevent this, as soon as the plants are of sufficient size to bear it, give them a good syringing every day, being particular to direct the water well to all parts of the leaves. In a Vinery at work, Camellias will also make their growth well after flowering; they can be placed in a corner by themselves, not too much crowded, and if the foliage of the Vines be not sufficiently advanced to give them the necessary shade, a piece of some thin material can be hung over them below the Vines. Every afternoon, when the house is closed, give them a good syringing, and do not on any account let them suffer for want of water to the roots. Before they are started into growth, if there be any scale on them, they ought to be thoroughly cleaned.

Forcing Pit.—To keep up a good supply of flowers on the plants for cutting as well as for decorative purposes—some more *Deutzias*, double *Prunus*, *Kalmias*, *Rhododendrons*, and *Ghent Azaleas* should be put in a house or pit where there is a little warmth. Such subjects as the above should not be put out-of-doors when they have finished blooming; they ought to have a place in a cold house or a pit, and when the season gets further advanced they can be planted out again.

Celery, sown in heat as recommended some time since, will shortly be large enough for pricking out; where it is required for use as early as obtainable, there should be prepared for it a slight hot-bed consisting of about 18 in. of fermenting manure and half-rotten leaves; on this place a two-light or three-light frame, with 10 in. of

rich soil, into which put the plants 1 ft. apart each way, giving a little water, afterwards putting on the lights, which keep close for a few days until the roots take hold of the soil; if the weather be sunny, shade in the middle of the day. As soon as growth has fairly commenced give plenty of air to prevent the plants drawing up weakly, and if well attended to as regards water they will progress rapidly. The lights should not be altogether dispensed with until all fear of frost is over; every alternate plant may then be removed with a good ball of earth and turned out into a well-prepared trench, leaving the remainder on the bed on which they have been grown, and when large enough earthing up with light soil brought in for the purpose; by this means, those who want Celery very early can have it in good condition by midsummer, but of course not large. It will be succeeded by that which was planted out from the bed, which will be ready before that grown in the ordinary way. The principal portion of the plants from the same sowing should be pricked out 3 in. asunder in a frame, in which put 6 in. of good soil on a firm bottom, composed of ashes well rammed, into which the roots will not penetrate far; for this purpose the soil should be of a light sandy nature, to enable the plants, when moved for permanent planting, to be taken up with little breakage of the roots. Where Celery is desired late, say until April the following spring, a little seed should now be sown, as this will stand longer without running to seed than the earliest sowing.

Cucumbers.—A good hotbed should now be made for a two or three light frame, according to the requirements, on which to plant out the Cucumbers sown some weeks back. This bed ought to be made 4 ft. or 1½ ft. high, the manure being well prepared. If the plants have filled with roots the small-sized pots, do not allow them to become stunted; they may be moved to others 8 in. or 9 in. in diameter, and kept in these till the bed in which they are to be planted is ready to receive them. It is well to have the plants a good size before being put out in the bed in which they are to be grown, as they will thus come into bearing before it gets cold, which will give less trouble in the application of linings through the weather getting warmer. If the seed-bed which the plants now occupy be getting cold add more heating material round the sides. A little Melon seed should also now be sown in small pots similarly to these recommended for Cucumbers; it will succeed in the seed-bed in which they have been raised.

Potatoes planted in frames at the time recommended will have made some growth aboveground, and must have plenty of air given them every day, or the tops will be drawn up weakly. It is not necessary to cover the frames at nights with mats unless there is an appearance of frost, as there will be sufficient heat yet in the bed to keep them growing, and the more light they receive the better. Carrots and Radishes in frames must also have plenty of air, and be sufficiently thinned as soon as they get 1 in. high.

Herbaceous Borders.—Most of the plants will be above-ground, and the mulching material put on early in the winter ought to be dug in; for this operation use a fork in preference to the spade. Should the Grass need edging, it can be done at the same time, thereby imparting to the whole a neat appearance. Be very careful not to disturb the roots of any kind of Lilies, as they, more than most subjects, are impatient of any interference at this season. Summer and autumn-blooming herbaceous plants, such as *Phloxes*, *Asters*, or any flowers that exist in large masses when the season is considerably advanced, it will be well to divide at the present time, as by this means their roots will be placed within reach of fresh soil, which will strengthen them and enable them to bloom better. It is necessary to keep well back in the border tall-growing plants of this description; but as far as possible avoid planting them where the ground is occupied with the roots of deciduous trees, as herbaceous plants have but a very poor chance of success under such circumstances; yet as in such situations it does not look well to have the ground bare, there is nothing better suited than the strongest tall-growing varieties of *Michaelmas Daisies* and *Golden Rods*, to assist which in such positions an extra liberal dressing of manure should be given every spring, digging the ground with the spade a fall spit in depth, which will cut off the protruding roots, and for a considerable portion of the summer spare the plants being affected by them. Any choice plants that are subject to the attacks of slugs will be benefited by an inch of coal ashes being placed round the collars of the plants, which, though it will not altogether prevent the slugs from attacking them, will in a great measure hinder them from harbouring under the plants.

Roses.—It will be well now to prune a portion at least of the stock of *Roses*, attending to the remainder in two or three weeks' time; the amount of pruning necessary will of course depend upon the strength of the variety, leaving the greatest number of shoots to those that are naturally of a vigorous, robust habit, and a less pro-

portion to those that are weaker. Cut the shoots that are to remain back to three or four eyes—all the rest get right out from the point of projection, not even leaving a single eye; by so doing the whole of the energies of the trees will be directed into the blooming shoots. Amateurs who have not had much experience in Rose growing frequently are so far mistaken in the operation of close pruning as to destroy the chance of anything like satisfactory blooming in the Tea or Hybrid Tea varieties, the most of which will only bear the use of the knife very sparingly. With these a considerable portion of the largest and strongest shoots should be retained, simply shortening them; and to prevent the heads getting too crowded some of the old growths ought to be well cut back a few inches from where they spring, and from this point just below where severed generally through the season will be produced some strong shoots that will form the best blooming wood for next year. By this means the trees will be continually furnished with flowering shoots. Roses on walls should regularly be induced to make young growth from near the base, otherwise they become unsightly, making little flower or leaf except at the upper extremity, to effect which a strong shoot or two should be cut out at about 18 in. from the bottom each year: the remaining portion will almost invariably push vigorous growths. In the case of those plants that break up from the bottom of their own accord, it is of course not necessary to resort to this treatment.

Kitchen Garden.—Sowings should be made of Cocoa-nut and Eufield Market Cabbages, Red Cabbages, Savoys, Veitch's Autumn Giant Broccoli, and Snow's Winter White Broccoli. Parsnips. —As soon as the ground is dry enough, these should be sown. Cabbages.—The soil should on a dry day be stirred amongst Cabbages planted in the autumn; it will be a good plan to draw some up to the stems of the plants: this is the more necessary if they have been at all loosened during the winter by the wind. Seakale, when the ground is in fit condition, ought to be planted; when its season for growth is long, it becomes stronger than if not planted till late. The stronger the pieces of root that are used for planting, the stronger, as a rule, will be the crowns that they make; pieces as thick as one's finger and from 6 in. to 9 in. long are the best; where, however, a sufficient number of these do not exist, smaller ones will do. Make holes for them with a dibble, letting the top of the piece of root be level with the surface; plant them from 15 in. to 18 in. apart. If there be a scarcity of roots, pieces of the crowns may be used for planting.

GARDEN WORK FOR EVERY DAY.

EXTRACTS FROM MY DIARY.

By W. DENNING.

March 19.—Potting and plunging Lilacs that have been forced. Potting off Balm, and boxing Calceolarias. Re-potting Dendrobiums and other odds and ends among Orchids. Shifting the *Calanthes* into peaty loam, sand, dried cow manure, and small crocks. Basking *Dendrobium Farmeri*, *D. Bensoni*, and re-mossing *Lælia anceps*. Sowing Carnations, Picotees, Asters, Stocks, *Tagetes*, *Love-lies-bleeding*, and *Prince's Feather*; also more Peas, Spinach, and a bed of Carrots. Planting Shallots and Garlic, first-sown Cauliflower plants, Lapstone Kidney and Early Handsworth Potatoes. Pricking out Onions. Potting in more Coleus, *Alternanthera*, and *Iresine* cuttings. Moving *Artemisia*, Calamint, Oxalis, and *Veronica*s into cold frames, and annuals into cool Vineries. Getting Violets in pots out of houses. Potting Cauliflower and Lettuce plants into cold pits, and another batch of Asparagus into a manure-frame. Digging vacant land. Forking among Gooseberry and Currant bushes. Staking young Vines. Syringing *Odontoglossums* four, and *Aerides* five times every day. Washing Apple trees in orchard with lime and soot-water. Wheeling manure on Asparagus-beds. Making a pit ready for Cucumbers. Earthing up Cabbage plants. Cleaning autumn-sown Onion-bed. Putting saucers under Strawberry pots. Keeping the orchard-houses in which the blooms are expanding at from 45° to 50° at night, leaving a little air on constantly.

March 20.—Potting young show Pelargoniums for late blooming and small Violets in 8-in. pots. Shifting *Cattleya*s into larger pots; also *Vanda cœrulea*, placing 60-sized pots, and Moss lightly among the roots. Sowing Cockscombs and Balsams; also Broad Beans, main crop of Parsley, and Long Surrey and James's Carrot. Planting Red Cabbage and Globe Artichokes. Dividing Dahlias; also Plumbago and scented *Verbena* cuttings, and layering *Jasminum azoricum*. Pricking out Tomatoes; staking Peas; watering all permanent Peach trees in houses. Manuring dwarf Roses; top-dressing *Camellias* with loam; taking straw off beds where Mushrooms are appearing; and thinning out *Mignonette*.

March 21.—Potting Dahlias and placing them in heat. Potting off *Lobelia*, Golden Chain and other *Pelargonium* cuttings. Shifting Tree *Mignonette* into 8-in. pots, using all manure with a top-dressing of loam and sand. Blocking *Cattleya Dowiana*. Pating peat and horse-droppings to *Odontoglossums*; slaking out and repotting those deficient in roots; also surfacing up *Masdevallias* with peat, Moss, and sand. Sowing *Waleheren* Cauliflowers, Pine-apple Beet, and Myatt's *Victoria Rhubarb*. Planting *Ambretia græca* and *Viola cornuta*; also Fortyfold Potatoes, Seakale, and autumn-sown Cabbage plants. Moving potted-off *Heliotropes* into greenhouse. Placing Seakale thongs in shed to sprout. Digging vacant land. Throwing out trenches and manuring for Seakale. Turning manure for hotbed on which to strike Pink cuttings. Thinning Strawberry fruits. Hoeing among growing crops. Weeding walks and cleaning up rubbish. Keeping Muscat Vines coming into bloom at from 68° to 70° at night, never admitting air until the temperature reaches 95° by sun-heat. Keeping *Hamburghs* in flower at from 66° to 68° at night, according to the weather.

March 22.—Potting Stocks as they show flower. Shifting young *Fuchsias* into 6-in. pots, and putting French Beans into fruiting-pots. Taking away as much soil from the roots of *Disas* as possible, and replacing it with an admixture of loamy peat and sand. Basking *Odontoglossum Rossi*, and placing it in Lyeaste-house. Sowing Seakale and Watercresses. Planting out Lily of the Valley that has been forced. Pricking out Celery plants, half Red and half White. Thinning out young Asparagus plants. Putting gravel on low places near doorways, and laying turf. Earthing up Broad Beans. Thinning fruit in Peach-house, leaving two on a shoot. Rolling rough gravel, and cleaning away straw and other litter from about pits, frames, &c.

March 23.—Potting Alyssum and examining Orchids in baskets. Sowing branching blue Larkspurs, Primulas of sorts, and *Amaranthus*; also Malta and Paris Cos Lettuce in heat; likewise main crop of Celery, and putting it in Cucumber pit, placing glass over the pots, more Chervil Radishes, and Meredith's Hybrid Cashmere Melon. Planting more Cauliflowers. Putting in some Golden Willow cuttings. Impregnating Primulas for seed. Protecting Jefferson and Kirk's Plum in blossom by means of netting. Putting down covers over Green Gage Plum trees every night. Searching for fly on Peach trees, and for thrips on Vines. Watering Potatoes in frames. Putting Broccoli fit for use under cover. Salting Asparagus and Carrots. Digging border for Turnips; also flower borders. Forking between Peas and Cabbage, and preparing beds for sowing Brussels Sprouts, Savoys, and Curled Greens. Putting fresh gravel under Orchid-house stages. Earthing up early Melons with good stiff soil; also first Cucumbers, and training out the shoots. Soiling Potatoes in frames; also hand-glass Cauliflowers. Salting walks to eradicate Moss.

March 24.—Sowing Yew berries and more *Perilla*; also Campbell's Melon, Cucumbers, Parsnips, and Turnips. Planting Carnations, Fairy Roses, and *Gladioli*; also Lapstone Kidney Potato, more rows of Cauliflowers between Early Peas, and dividing and replanting Pennyroyal. Pricking off seedling *Petunias*. Putting variegated *Pelargoniums* into cold pits. Watering inside borders of Muscat and *Hamburgh*-houses. Putting up the shading in *Vanda*-house. Preparing land for Sweet Peas. Digging among *Rhubarb* stools. Putting in manure for *Hollyhocks*. Fumigating Orchid-houses to kill thrips and green fly.

Orchids.

At this season of the year particular attention should be paid to unhealthy plants, should there happen to be any, with a view to their re-establishment. In this the cultivator will be materially aided by the increasing length and brightness of the days, and by the efforts made by the plants themselves to get into good condition. Re-potting, re-basking, or blocking a plant in bad health is one of the first things to be considered, and in doing this care should be taken that the plant is placed in as small a pot or basket as possible, and that it is supplied with good fibrous peat in lumps, living Sphagnum Moss, or a mixture of both, as the case may be. Some mix silver sand with the material used for potting Orchids, particularly for unhealthy specimens; but although by retaining the moisture round the plants it may appear to be beneficial for a time, experience tells me that it is injurious to epiphytal Orchids. If the plants root in such material the sand becomes embedded in the tender gelatinous points of the roots, thereby stunting and distorting them; it also, by keeping the material close, excludes air, which is of almost as much importance to the roots as to the leaves. Although most epiphytal Orchids undoubtedly succeed better and require less trouble when grown in baskets or on blocks, either suspended or placed on stages, than when grown in pots, and although some are known, as a rule, to succeed best in

Sphagnum Moss, and some in peat, the potting or basketing material to be used must be regarded as matters of secondary consideration. One of our best Orchid-growers remarked, when speaking of *Dendrobium Devonianum*, which was supposed at that time to be very delicate, that he could grow it as well in turfy loam as in fibry peat; and this has been done, although turfy loam cannot, as a rule, be recommended for this *Dendroble*. The preservation of a proper and genial temperature, resorting as little as possible to artificial heat, the admission of plenty of light, and the exclusion of the burning rays of the sun, the maintenance of the requisite amount of humidity, the strict observance of the growing and resting seasons, and, above all, the admission of pure air by means of ventilators properly arranged, whereby the air may be induced to circulate freely through the house without causing draughts, are matters of the first importance in Orchid culture: and to these the attention of the cultivator should be specially directed, otherwise the care bestowed on potting, basketing, or blocking—which is now in active progress in the case of the general collection—will be comparatively valueless.

—JAMES O'BRIEN.

Indoor Fruit Department.

Pines.—Plants now in fruit must have sufficient water to keep the soil in a moist state. Examine them twice a week to prevent them from becoming dry at this particular stage, which causes the fruit to become one-sided and stunted in growth; if out of flower, let them be occasionally bedewed overhead, and the paths and all other surfaces damped with the syringe. Now that the light is increasing, the night temperature should range about 70° in mild weather, with a rise of 15° or 20° by day, according to the temperature outside. Where late winter fruit is still on hand, have all brought together, and subject them to a few degrees more heat; place them in a stove in a bottom-heat of 90° with abundance of moisture. It being necessary to make a growth beforehand, plants intended for fruiting in October should be gently grown on with a view of resting them in May; let the night temperature be at 65°, with a bottom-heat of 80°, admitting a small quantity of air during the dark hours to prevent them becoming drawn. Autumn suckers, as a rule, at this season are shifted into their fruiting pots, and during their progress should receive every attention. See that the roots thoroughly penetrate the balls of earth, as nothing is gained by a larger pot before the plant is fit to take to the fresh soil, and by a careful examination of the roots one is able to discover whether or not they become too dry, which condition should always be avoided—especially previous to their insertion in fresh soil, and where any plants have become soaked through drip or bad drainage, let them be shaken out entirely. Where new tan is introduced, prevent the bottom-heat becoming too intense by shaking the pots, 60° at night being sufficient with a bottom-heat of 80°. All soil should be thoroughly prepared before starting by keeping it in a place with a moderate temperature for two or three days. A compost consisting of a good fibry loam well sifted, and of a fair sprinkling of bone-meal mixed with a little soil, is necessary for their well-being, and let the pots be well crocked, not too deep, but cleanly and covered with Moss. Good suckers on winter stock, after having been taken off and potted, will root readily at this season. Prevent overcrowding, and refrain from placing stove plants among them, such being generally the cause of the Pines being attacked by white scale.

Vines.—Where the crops in early houses have been thinned, and are now swelling freely, they may be pushed sharply along by day; avoid hard forcing by night, 65° being sufficient, with a little air on for Hamburgs; on all occasions when ripe fruit is wanted to time, let the pushing be done by daylight; timely stop all young shoots and side-growths; two leaves beyond the bunch where lateral leaves are encouraged are sufficient (I prefer a few leaves more on the main stems), and pinch out laterals. Care must be taken not to overcrowd, admit as much light as possible, and take every advantage of the sun in shutting up; make repeated examinations of the borders to prevent them becoming dry; well water them when needful—giving tepid guano-water of the usual strength when obtainable. Where the Grapes are colouring withhold manure-water—this applies to Vines either in pots or borders; increase the air, and keep the atmosphere somewhat drier. Where old Grapes are still hanging on the Vines, they should be cut and placed in bottles of water, with a few pieces of charcoal to prevent the water becoming putrid. In any pruning yet to take place the wounds twice should be dressed with styptics; remove all rough, loose bark, and well wash with soap and water, and tie up the rods in their fruiting positions. Young growths in succession-houses should be tied in carefully and betimes, otherwise the strongest of them will snap off at the old wood; this applies to the strongest growths. Late Vineries should now be started where good flavour and keeping qualities are to be combined, late starting being injurious to both. Keep a sharp look-out for

insects, especially when the Grapes are stoning. Red spider generally puts in its appearance at that time, for the removal of which pest hand-wash on its first appearance; in dark, dull localities, mildew at this particular season frequently attacks the Vine, a cure for which will be found in Speed's Annihilator, syringing afterwards, otherwise the foliage will be affected. Where young Vines are to be planted, all border-making should be brought to a close, especially if green turf be used, when the border should be turned over before planting, to prevent overheating.

Peaches.—In this department of indoor forcing it is necessary to proceed with caution before the stoning of the fruit takes place. First and second houses in this locality are furnished with plenty of well-set fruit. The first should not exceed 58° at night, and the second 55°, with a circulation of air during night; when the stoning has commenced, 5 more will be needful if early fruit be required, shutting up in fine weather with as much sun-heat as possible, and well syringing the trees and all available surfaces. Disbud succession-houses betimes, and keep a sharp look-out for green fly, which fumigate on its first appearance, otherwise the foliage will become yellow and drop. In cases where the trees remain to be pruned that operation should be brought to a close, as the buds, when fairly started, are easily rubbed off, and the difficulty of washing and cleaning the trees and houses is thereby considerably increased.

Figs.—If all have gone well with the first crop they will be swelled and fit to gather soon. A night temperature of 60°, and a corresponding rise by day, should be afforded them, with every attention to watering, and in no stage of growth should Fig trees be allowed to become dry. When the pots are filled with roots, water with manure-water at a temperature corresponding to that of the soil. Where good drainage exists abundance of water is requisite, using the syringe freely daily, giving air on all favourable occasions, and allowing plenty of light, which will prevent them becoming drawn, and add material to their fruiting powers. Start later houses (after having been thoroughly cleansed) by well watering the borders and damping the houses frequently, keeping a night temperature of 50°. Pinch all young shoots when three or four leaves have been formed; where shoots are wanted stop the flow of the sap by making a deep incision in front of the eye; disbud where the fruit is thickly set together.

Strawberries.—In many instances the fruit will be ready to gather, and in such houses a circulation of air should be maintained to insure good flavour. After colouring begins cease to give manure-water, and refrain from syringing overhead, 55° at night being ample for the setting of the berries, but where time is short 70° may be maintained, with a free circulation of air during the night, taking every advantage of sun-heat during the day. Where the plants are used up for planting out, it would be better to have the protection of a frame and gradually harden them off. Introduce a fresh stock according to demand—300 or 400 make a good succession—remove all the yellow leaves from the necks of the plants, and let all inert soil be shaken off. Top-dress with a good rich loam, and ram the soil down firmly. Expel worms from the pots by the aid of lime-water, putting the lime into a tub the day before and well stirring it; run off the water when clear the following day, and use it when the plants are introduced into heat.—J. HUNTER.

RAISING VERBENAS FROM SEED.

THE matter of raising Verbenas from seed is really a simple one as practised by our leading Verbena raiser, Mr. Henry Eckford. I remember calling on him once when he was at Coleshill, and inspecting his bed of seedling Verbenas, and in course of conversation he communicated to me the following details as to his method of raising seedlings, in which he was always most successful. Starting with the obvious truth that no one should attempt to raise seedlings unless from a strain of seed that would be likely to produce something worthy the time and attention of the cultivator expended on the process, he went on to say that he always made a point of sowing about the middle or end of March, in any convenient-sized pots, using a good rich loam, and covering the seed with soil to the depth of a quarter of an inch; he then placed the pots in a temperature of 65° or 70°, and kept the soil constantly moist. In the course of three or four weeks the young plants were large enough to handle, and then they were pricked off, 2 in. apart, in pots of soil. As soon as they began to establish themselves they were then gradually hardened off till they were fit to occupy a cold frame. The great danger of keeping Verbenas in heat is that they are apt to become affected with red spider; and when once they get infested in that way, it is very difficult to get rid of it. As soon as the weather was sufficiently favourable, generally about the beginning of May,

Mr. Eckford used to plant out his seedlings in a well-prepared border to bloom, and the ground was kept clear of weeds till the plants flowered; all the most promising were duly marked, and worthless varieties were pulled up and thrown away. I was always struck with the remarkable vigour of constitution shown by Mr. Eckford's plants. The late Mr. C. J. Perry, who in his lifetime raised large numbers of fine Verbenas, used to grow all his plants in pots under glass; and as he used to make their value for exhibiting purposes a leading point, the habit of many of his choicest varieties was the reverse of vigorous; on the other hand, Mr. Eckford always made vigour a leading test, as he steadily kept in view the value of the Verbena as a bedding plant, and his seedlings being flowered in the open air, a good test of this could always be afforded. When a promising variety expanded its flowers, a hand-glass used to be placed over it to protect the blossoms from being disfigured. It should always be borne in mind that the Verbena likes rich soil and an open situation, and therefore Mr. Eckford always advocated a liberal use of well-decomposed manure when a Verbena bed was prepared. In the course of raising his fine varieties he trusted more to a very careful selection of the best flowers to seed from than to

FLOWERING PLANTS FOR PLEASURE GROUNDS.

It cannot be denied that the present system of flower gardening has been overdone. In many places all has been sacrificed to this Moloch of modern gardening, and many a fine tree has been ruthlessly destroyed, and many a pretty picturesque situation sacrificed to make way for the uninterrupted straight lines and curves which are found necessary to the carrying out of some ribbon border. We have run the risk, too, of losing many fine plants which, simply because they could not be made to conform to the rigid requirements of the ribbon border, have been condemned, and either relegated to some out-of-the-way place or entirely discarded. It is the reckless conduct in this respect which has caused many to brand the bedding system as a mistake, and we can hardly be surprised at the harsh things which are sometimes said respecting it. A change in the public mind has, however, been observable lately. The more extensive culture of the Lily tribe and many other families of hardy summer-blooming plants, has directed attention

Dance on a "Big Tree" Stump.

fertilization. When crossing was resorted to, a very fine camel's hair brush was used, inserting it very carefully in the tube of the flower—an operation by which the pollen was transferred to another flower without, however, attempting to remove the natural pollen, which in Mr. Eckford's opinion would have proved a tedious operation, if indeed it could be done without injuring the flowers. A bed of Verbenas should consist of mixed colours, and not wholly of any one variety. Charming effects may, with a little care, be worked out in this way.

D.

Dance on the Big Tree Stump.—Among the various ways of giving an idea of the vast size of the Pines in some parts of the Sierra Range in California few are more suggestive than the engraving this week, which represents an actual occurrence after the cutting down of one of the biggest of the sound trees, some of which, it will be remembered, are nearly or quite 40 ft. in diameter. The species in question is the Wellingtonia or Sequoia, the greatest of the region as regards size of trunk, but which is rivalled in height by other trees of the same locality, as, for example, the Douglas Fir and Redwood in the districts most favourable to their growth.

to the fact that there exist many plants of easy culture which, although not coming within the catalogue of bedders, may either be used with advantage in their stead, or, at any rate, serve as a pleasing contrast to them. For those who can command plenty of glass accommodation, the production of bedding plants is a comparatively easy matter; there exist, however, many places where this is not the case. Many have not the means, or are unwilling to incur the unavoidable yearly outlay which the bedding system entails. Beyond a few beds within the immediate vicinity of the mansion, very little is done to secure an adequate floral display, and this simply because the expense of propagating and preserving the plants during winter is too great. This consideration proves, too, a great drawback to the occupants of villa gardens; they have not the convenience to keep up a stock of bedding plants, and are not disposed to go to the necessary expense in the spring of providing a sufficient quantity to satisfy their requirements. Now in order to have a beautiful display of flowers in summer, it is not so absolutely necessary to have a large stock of the so-called bedding plants; in fact, they may be dispensed with to a much greater extent than is

generally imagined. In most places, however, there will exist convenience for wintering a certain amount of them, and provided suitable kinds of plants be chosen, and a proper method of propagation and storing followed, a good quantity of plants may be preserved in good health in a limited space. Care and strict attention during the winter months have much to do with obtaining satisfactory results; but the mainspring of success will be found in the preparatory autumn treatment of the plants. Only the hardier kinds of bedding plants should be chosen, as the more vigorous the constitution the closer they may be stored together. In the way of

Pelargoniums,

for example, only the Scarlet and Zonal varieties should be selected. There are many different ways of propagating these plants; some dibble them in the open ground in August, and when fairly rooted, pot them singly in small pots. In this manner ninety-nine out of every hundred will strike root, and there is less labour in attending to them than if treated otherwise. Others, again, just put the cuttings singly into pots, and do not disturb them until planting-out time arrives next spring. Either method is good for those who have plenty of room, but for others who must make the most of their space, I should recommend a different method from either of the abovenamed. Take 48-sized or 32-sized pots, drain them well, and fill half full with a good, rich compost of equal parts of loam and well-decayed manure; fill up to within 1 in. of the rim with some well-pulverized soil, to which a third of silver sand has been added; then not later than August take fair-sized cuttings, selecting them with the wood in as matured a condition as possible. If the season have been a moist one, the shoots will probably be rather succulent and tender; in that case, after being made they may remain a day or two before being inserted. The superfluous sapesapes—a circumstance which diminishes the chances of rot. About a dozen cuttings may be put into a 32-sized pot, making the soil as firm as possible round them; then set them in a frame and give them a moderate watering. Air should be constantly left on, and shading should only be applied on very hot days. In this way, and by careful watering, nearly every cutting will strike. As soon as they are rooted, the sashes should be left off night and day, except during heavy rains, and the plants should not be housed much before the middle of October, the object being not to excite growth, but rather to retard it. Thus treated they will be able to resist the fluctuations of temperature and comparative absence of light with which they may meet in their winter quarters. The two main points to be considered in this matter are early propagation, in order that they may be well rooted before winter sets in; and thorough exposure, so as to well harden them before putting them under cover. A great quantity of cuttings made in this way may be stored in a small space, and will be found to give greater satisfaction than old plants taken up and potted late in the season. The tricolor section I should not recommend for this purpose; they are very effective bedders, but, unless they can be wintered in a light, dry house, they come out so debilitated in the spring that nearly half the summer must elapse before they recover sufficiently to show their true character.

Verbenas.

If Verbenas be desired, then only kinds possessing robust constitutions and free-growing habits should be selected—one good scarlet, one white, and one purple are enough. Many of the newer kinds in cultivation are defective in vigour, and are better suited for pot than for general outdoor culture. One of the principal points to be observed in order to ensure success in Verbena propagation is the selection of suitable cuttings. In hot dry summers cuttings of Verbenas often fail, as the wood becomes stunted and hard; it is only late in the season that they recommence to make growth, and, as early propagation is in their case necessary, we must take precautions to ensure the needful supply of cuttings at the season required. To effect this, a plant or two of each kind should have their blossoms kept cut off from the end of June onwards, and they should be well supplied with water in dry weather. If a spare corner can be devoted to this purpose it will be preferable, as in that case the soil can receive such preparation as will secure

free growth; 2 in. or 3 in. of a mulching of rotten manure will do much good. From plants thus treated a plentiful supply of cuttings will be obtainable and of such a free healthy character that they may be relied upon to strike root quickly. For striking Verbenas, 48-sized pots are perhaps best, as with pots of that size the amount of moisture is more easily regulated, and excess of moisture can be better avoided than if the pots were larger. These pots should be filled quite a fourth full of drainage, and then filled to within 2 in. of the rim with a fairly rich soil, which must be surfaced with an inch of silver sand. It is well to give the pots a good watering some few hours before using them. There are two kinds of cuttings; they can either be made of the terminal shoots cut to a joint with several pairs of leaves attached to them, or they may be made of eyes, that is to say, simply leaving one pair of leaves with as much of the stem below the joint as possible. These, if inserted quite up to the leaves, root all up the piece of stem in the soil. By the former method, larger and stronger plants are of course obtained, but by the latter method a greater amount of plants, and this is a desideratum when the stock happens to run short. It is, however, useless to put in cuttings of this description if the stems have become hard and wiry, as even if they do root, the plants never acquire a free habit of growth, in fact, no success can attend Verbena propagation unless the wood is soft and succulent and free from all insect plagues such as red spider. If the stock plants have, however, been kept well supplied with moisture, red spider will not be troublesome. When the cuttings are put in they should be immediately placed in a frame, and if possible on the north side. They should be kept close and shaded during the heat of the day, but air should be given at night, and, if the weather be calm, the lights should be drawn off, the heavy dews which often succeed the hot days of August being extremely beneficial to them. Although excess of moisture is to be guarded against, Verbena cuttings must never be allowed to get dry or flag, for if this takes place once, no reliance can be placed on their making satisfactory progress. By this manner good, full, healthy pots of cuttings will be obtained, containing some twenty plants each, which, if well exposed for two or three weeks before housing, will pass the winter satisfactorily. One seldom sees a really good potful of Verbena cuttings; the pots being often patchy, or two or three vigorous, and the rest feeble. This often arises from the unsuitable condition of the cuttings when inserted; they have either not been selected with care or the plants may have suffered from overblooming. From hundreds of plants in that condition I have often failed to get as many good cuttings. To this cause may be traced many of the failures in Verbena culture—the plant starts with a feeble constitution, and weakness begetting weakness, the cuttings taken in the spring retain more or less of the constitution of the parent plant, and are thereby rendered more liable to any disease which may overtake them. There is one other method which I have successfully practised in striking Verbenas, and which possesses the merit of simplicity:—I take some ordinary pot saucers or flats without holes, fill them to within 1 in. of the rims with silver sand, insert the cuttings, and fill up with water, and set them out in the open sun. Care must be taken that they never suffer from want of water, and they will strike readily. If the saucers be kept filled they will not flag, and, being subjected to great solar heat, they quickly root. To those who have not much time to spare and are liable to be absent at times, I should recommend a trial of this method, as beyond seeing that there is sufficient water, there is not much attention required. They will not, of course, make such strong, vigorous growth as those struck in pots, which have the advantage of a good body of soil in which to root.

Miscellaneous Plants.

Calceolarias should not be put in till the middle of September, as they seldom make suitable cuttings until the moist, cool nights arrive. They should be kept in cool frames as long as possible; a dry, harsh atmosphere checks and cripples, and renders them very susceptible to the attacks of green fly. Ageratums, which are valuable on account of the colour of the flowers, blue being comparatively scarce, should be struck about the latter end of August, and, if well rooted, they will

winter well even under indifferent accommodation. Lobelias should be sown about the middle of September; the best thing in which to sow them is a shallow box: by sowing in September they will become hardy little plants, and may be pricked out in frames about the middle of March, or under a hooped roof in April. They may then be transplanted into their permanent places without a check. Small plants, treated in this way, will generally do better than plants in pots; the roots are not injured, and, if carefully transplanted, strike into growth at once. Petunias may be raised from seed in the spring; they should be pricked out into shallow boxes when the young plants are large enough to handle, and kept rather close and somewhat moist for a time, in order to induce rapid growth; they should then be hardened off, and by the latter end of May they may be placed in their permanent summer quarters. A bed of Petunias is both beautiful and interesting, especially if the colours be well intermixed; and a packet of seed of a good strain will afford a vast amount of variety. A bed of the double kinds, when the plants make good growth, is strikingly effective, the colours being soft, delicate, and harmonious.

Wintering Half-hardy Plants.

I have now alluded to the most indispensable of the so-called bedding plants, and such as will be found to be the most easily wintered where but a limited and inadequate amount of heated glass structures exist. Those who only possess cold frames may try all the above-named subjects with every hope of success. The worst enemy in unheated structures is damp. It often happens that coverings cannot be removed for a lengthened period, and when that is the case there will be sure to be considerable damage done; however, with care as regards cleanliness and giving plenty of air on all favourable occasions, a considerable amount of plants may be saved. The various kinds of Centaureas, *Echeveria secunda glauca*, *Cineraria maritima*, &c., require no other care than the protection of a cold frame, or even wooden shutters to throw off the wet, covering them up in hard weather. Now, I am supposing that even by economising house-room to the fullest extent the supply of plants remains very inadequate to the requirements of the pleasure grounds; it is, therefore, evident that we must seek further afield to supply the deficiency; and when we consider the variety of

Annuals

now in cultivation, and how extremely effective they are when well managed, and how easy of culture, the wonder is that they are not more extensively used than they are. I do not mean that other plants should be discarded, but they might be used to supply unavoidable deficiencies instead of long reaches of naked shrubby borders and meagre-looking beds, such as one often sees a really good show of summer bloom may be created, and that, too, with a comparatively small amount of labour. Let us take, for instance, Asters; what a variety of form, colour, and habit of growth do we not obtain among them! They may be either ribboned out with regard to their different shades of colour, or they may be massed or dotted here and there amongst shrubberies. In whatever way they may be used they fill up large gaps, and as regards brilliancy they have few equals. Now here is a plant, of which a good supply may be obtained with a relatively small amount of labour. No winter care is required in the case of this class of plants; operations need not commence until the most trying time is passed, and then all that is necessary is a slight hotbed on which to raise the seed, and a piece of well-prepared soil in the most sheltered spot that can be found, so that a mat may be used as a covering. Whether in large or small gardens these two requisites will not be difficult to arrange. In small places a one-light box and a few barrowloads of manure will amply suffice; where a larger space is to be furnished, greater appliances will have to be provided. With one season's experience the amount of seed to be sown and the room required will be accurately ascertained. The seed should be sown in pans about the middle of March, and placed on the hot bed; as soon as they young plants are fairly up they should be removed to a cold frame and gradually inured to the air, in order that they may become

hardy and be kept dwarf and stocky. By the time they have made three or four leaves, they will be in a suitable condition for transplanting; prick them out in the beds of previously-prepared soil already mentioned from 4 in. to 6 in. apart; here they may remain until required for use. It is highly important that the soil in which they are pricked out should have been thoroughly pulverised and fairly enriched; a sprinkling of soot worked into it will be found beneficial. The planting out, too, should be done after a few days' genial weather, when the surface-soil shall have become somewhat warm. The mats should be put on regularly at night, and on very wet and cold days it will be better not to remove them. Many consider it necessary to prick the seedling plants into pans a second time, or pot them off singly; this method, however, causes a vast amount of after labour in the way of watering, &c., and cannot be practised on a large scale. By the plan just described labour is economized, and the results are in every way more satisfactory, for the following reasons:—The plants, having a more extensive root-run, develop much better, and when taken up with a good ball of fibre they thrive better than when turned out of a pot. Then, again, if there be a pressure of work, they may be thinned out and the rest left until there is time to attend to them; some, too, may remain permanently, to be potted when fully grown if required for conservatory decoration or to fill up blanks which sometimes occur later in the summer. The above treatment will apply, with but slight modifications, to many other of the principal kinds of annuals, such as Balsams, German Stocks, Phlox Drummondii, Portulaca, Zinnia, and French Marigolds; the two latter I should much recommend, as they are showy, cover the ground well and quickly, and last long in bloom; they are better adapted for edging, shrubby borders, and for planting in dwarf plantations, associated with such plants as Dahlias, Marvel of Peru, climbing Tropæolums, &c., than they are for forming regular beds.

There are, of course, many kinds of annuals which do not require even the labour and trouble just described, such as *Eschscholtzia*, *Sanvitalia*, *Mignonette*, &c., all of which may be sown where they are to remain and flower. In fact, with the enormous variety of annuals now in cultivation a garden may be kept gay the whole season through almost entirely without the aid of the usual bedding plants. In order to effect this, a special study must be made of the times of sowing, &c., so as to ensure a succession. I have known gardens in which flower-beds were kept in a blaze of bloom during the whole summer by means of annuals, which were sown and grown in pots expressly for that purpose; they were plunged in the soil when nearly in bloom, and the supply being kept up, the beds were always in perfection. The labour certainly was great, but the result was most satisfactory, the beds being always gay and always varying. I cite this merely as an instance of what may be done by means of annuals, and my object in recommending some of the principal kinds for more general cultivation is to enable all to have a gay garden in summer, and to help where there is a large space to fill and but limited means for doing it. There are, of course, many other showy plants which may, with but a slight amount of care and management, be made very useful plants, which, instead of being merely seen as single specimens, should be massed, in order to obtain a good effect. JOHN CORNHILL.

Byfleet.

LYCOPOD CONES AND PYRAMIDS.

THESE interesting plants, besides being capable of being grown in the form above indicated, can also be grown in ordinary seed-pans, from 4 in. to 6 in. deep, and from 6 in. to 16 in. in diameter. The soil that I employ is good turfy peat one-half, leaf-mould one-fourth, and as much silver sand added and well mixed through it as will keep the whole open and porous. This compost we never sift nor chop with a spade, but pull it to pieces with the hands. Those who cultivate these plants need not be afraid of the soil being too rough, for it is best when the lumps are quite the size of pigeons' eggs. Before attempting to build the cone, the number of plants likely to be required must be struck for the purpose. For a cone 5½ ft. high from the ground, about two hundred plants will be required; for one of smaller dimensions, a proportionately smaller number will be necessary. This is the best time in the year for striking the cuttings, and if

healthy plants be put in at once they will be rooted in three weeks. The cones may vary in size and height, from 2 ft. to 6 ft. and upwards according to the space and convenience at command of the cultivator. We have them growing from 4½ ft. to 6 ft. in height, and they are beautiful objects in the conservatory, and form a fine background for such bright-flowering subjects as Azaleas, Deutzias, &c. For making a cone, a strong iron frame will be required, of the height to which it is intended to build the pyramid. Instead of the trellis being attached to a pot, we have dispensed with this, and substituted a block of wood turned upside down. When we used pots, we found great difficulty in moving the cone from one place to another; the mass of coil caused it to be top-heavy; the pot was in danger of being broken, and thus upsetting the whole fabric. As the soil is not required in the pot, but above, we now use a block of wood about 19 in. or 11 in. wide at the rim, and 14 in. or 15 in. wide at the base, with a hole through the centre to allow the superfluous moisture to escape. The trellis must be wired prettily closely; the rings should be more than 2 in. from each other, and the uprights must be made secure to the block. We then put a large crock over the hole in the centre of the block, and a few smaller pieces; then all is ready for fixing in the plants. A few tough turves are secured, and from these we cut narrow strips, half an inch thick, or less. A course of these strips is placed inside the trellis, which in its turn is filled with the prepared compost for the plants, and then a layer of plants. We just make the plants secure in their position, and then add another course of narrow strips of turf, which is again filled in with the compost, and then another course of plants, and so on to the top. The chief points in building the cone are to make the whole solid as the work proceeds, and the junction where the plants are inserted should be as near half-way between the wires as possible, that there need be no danger of the roots being broken by any vibration of the cone when moved from place to place. The work should be done neatly and cleanly, and, when finished, the whole should be carefully watered with clean water, delivered from a fine-rose water-pot. The first watering should be sufficient to moisten the whole mass of soil; afterwards the watering need not be heavy, but frequent. From the fact that the plants are growing in a pile of earth, exposed on all sides to the drying influence of the atmosphere, it is obvious that they do not require a deluge at once, but they must have it frequently. As soon after the cone is made as possible, just while the plants are inclined to droop a little, we peg all the shoots close to the earth, and the small roots, as soon as they are formed, run into the new soil; and the extra food thus secured gives an increased impetus to the plants. The plants are struck in February, and the cones are built up in March, and during the summer season they are under the shade of Vines. By the middle of September they are fully developed, when they are moved to the conservatory, and continue in excellent health until the September following, when we have a fresh set ready to succeed them. The best *Lycopods* I find for growing as pyramids are *L. denticulatum*, *L. variegatum*, *L. Mertensi*, *L. Mertensi variegatum* (the variegation of this often runs out), *L. formosum*, and two or three forms of *L. stoloniferum*. *L. formosum* makes the handsomest cone; and *L. denticulatum variegatum* throughout the winter season resembles a pillar of snow. This latter must be seen for its beauties to be appreciated. R.

VANDA CATHICARTI.

EARLY this week we saw at Glasnevin, for the first time, a flowering specimen of this *Vanda*, which is regarded by Dr. Hooker as being "by far the noblest species of the noble genus to which it belongs." As regards mere floriferous show and beauty, however, we scarcely feel inclined to go this length, for in these respects *V. suavis*, *V. insignis*, *V. cœrulea*, &c., are perhaps more striking; otherwise we entirely subscribe to Dr. Hooker's dictum as regards this grand and most interesting species. The plant itself a good deal resembles the well-known *Renanthra cœcinea*, but is somewhat stouter. The flowers, which are borne on a pendent lateral spike, are quite marvellous in their substance, structure, pencillings, and polish. Individually, each is roundish in outline, wax-like in substance, and about 2 in. or 2½ in. in diameter. The sepals and petals are concave, somewhat incurved at the edges, and on a ground of pale yellow or straw they are singularly and beautifully streaked transversely with pencil-like lines of chocolate red. The lip, in itself a study, is smaller than the petals, reniform in shape, having a crenelled margin of yellow, the centre and central ridge white, and in substance and gloss resembling polished ivory or porcelain. The mechanism by which the lip is hinged at the base is so delicate that the slightest touch or movement causes it to oscillate freely by its own weight. The column is very massive and striking, notably so by reason of the two eye-like processes which from the apex seem to mimic and stare at you like a thing of life. As far as we know, the plant at Glasnevin is the first

which has flowered in this country. To Messrs. Veitch, we believe, attaches the credit of being the first to flower it in England, somewhere about the year 1870. It is still, however, a rare plant in collections. It is one of the many valuable and interesting discoveries of Dr. Hooker in Northern India, where he met with it many years ago. Its successful introduction to Europe is, however, of only very recent date. The normal number of flowers on a spike is about half a dozen; but we doubt if any specimen yet flowered in British stoves has shown that number.—"Irish Farmers' Gazette." [This plant first flowered in England in Mr. Charles Stead's collection at Baildon, near Leeds, in 1869, and again in 1870; the specimen in question was 6 ft. in height, and it bore five spikes, each being furnished with from four to six flowers. The plant grows best in a partially shaded East India-house or plant stove, where it is syringed several times every day during hot weather. It grows more luxuriantly than any other *Vanda*.]

JAPANESE VASE GARDENING.

THE Japanese are now well known to be the most enlightened of all the Indo-Chinese races; hence it is not surprising to find that gardening in Japan is, as it has indeed long been, in a highly developed state; and although Japanese progress has necessarily not been exactly in the same direction as our own in matters horticultural, nevertheless the results obtained are

A Japanese Vase Garden.

none the less remarkable; indeed, their popular plants, most of which are improved cultural forms of their own indigenous wild flowers, are always welcome to our gardens; and this is especially so in the case of Chrysanthemums, Lilies, Irises, Primroses, Hydrangeas, and hardy evergreen and flowering shrubs of various kinds made familiar to us by Fortune, Lobb, Siebold, and other Japanese travellers and collectors. Among other systems of culture the Japanese cultivators are especially noted for their skill in dwarfing many of their most popular trees and shrubs, such as Oaks, Plums, Almonds, and Conifers, these being employed in various ways in the decoration of their dwellings. At a recent meeting of the Royal Horticultural Society, Mr. Moseley, late of the "Challenger" Expedition, exhibited a series of highly interesting Japanese books illustrated with native wood engravings, showing the culture of silk and Rice; one volume, too, was especially devoted to the illustration of miniature indoor gardens formed of dwarfed trees, shrubs, and flowering plants of different kinds, these being arranged in bowls or vases of copper, bronze, or porcelain, varying from 12 in. to 18 in. in diameter. We have all heard of a "storm in a tea cup," but in a bowl about the size of an ordinary soup plate, the Japanese florist contrives to form a landscape garden consisting of hill-side, rocks, rivulets, waterfalls, and other imitations of natural scenery, the whole embellished with living, growing, and flowering, and even fruiting trees and shrubs of proportionate size, as shown in our illustration sketched from a Japanese work now before us, and in which there are figures and directions for the due elaboration of these miniature gardens. Notwithstanding the fact that these, from our point of view, are

merely toy gardens, they are very popular in Japan, and some of the best examples are not only highly esteemed by their owners, but are willingly purchased at what would to us seem enormous prices by the wealthier native amateurs, these high prices being due to the fact that the time occupied in dwarfing and thoroughly establishing some of the trees and shrubs employed varies from five to twelve years.

B.

THE KITCHEN GARDEN.

POTATOES, AND THEIR PRODUCTIVE QUALITIES.

EARLY last year I had a piece of ground well prepared for Potatoes by dressing it heavily with rubbish-heap refuse, consisting chiefly of vegetable matter, no Couch Grass or Bindweed being allowed to be taken there; these are always taken to the smouldering heap. The ground was then trenched three spits deep, putting the material just named into the bottom of the trench, and laying the soil up in ridges 27 in. wide. In April I had the furrows drawn a little deeper, in which I planted the Potatoes, covering thickly, and almost level with the top of the ridges, with a mixture of burnt earth and other rubbish, such as hedge-shearings, prunings, &c., and leaf-mould and lime which had been well mixed, and which had laid for some months before being used. The crop was dug from the 4th to the 9th of September, and the following is the average weight of 10 ft. of the rows, linear measure, the distance of each sort, from row to row, being 27 in. Brownell's Beauty, produce from 10 ft., 28 lb. 14 oz., remarkably clean-skinned and fine in appearance, very few small, no disease, a sort which, when better known, must soon get into general cultivation, fine in quality when cooked. Early Rose, 25 lb. 12 oz., good in size, dead ripe, no disease, of fair quality when cooked. Brosee's Prolific, 25 lb., good in size, not ripe, no disease, grown out, close in quality. Red Flukes, 24 lb. 13 oz., worthless from growing out, haulm growing, no disease, very close in quality. Early Vermont, 22 lb. 6 oz., good in size, no disease, dead ripe, of fair quality. Violet-eyed, 21 lb. 10 oz., good in size, tops green, tubers ripe, fine sample, excellent in quality, a local sort, similar to the Fortlyfold, but with no white on it, eyes violet or purple, a heavier cropper, a first-rate second early, and an old favourite sort in this neighbourhood. Advancer, Cattell's, 21 lb. 3 oz., good in size, no disease, tops green, tubers ripe, and of fair quality. Griffe Castle, 21 lb. 1 oz., good in size, no disease, tops green, very much grown out, close in quality. Marquis of Lorne, 20 lb. 12 oz., good in size, no disease, ripe, clean-looking, and good in quality. Fortyfold, 20 lb. 5 oz., good in size, no disease, tops green, tubers ripe, and excellent in quality. Improved Victorias, 20 lb. 4 oz., good in size, no disease, not ripe, begun to grow out, good in quality. Late Rose, 19 lb. 13 oz., very large, no disease, ripe, of fair quality. Jersey Blue, 19 lb. 11 oz., good in size and quality, tops green, unripe, became very much affected by disease after being taken up. Extra Early Vermont, 19 lb. 11 oz., very large, no disease, dead ripe, good in quality. Dalmahoy, 19 lb. 2 oz., good in size, no disease, tops green, tubers ripe, good in quality; became much affected by disease after being taken up. Williard, 18 lb. 11 oz., good in size, no disease, dead ripe, very close and inferior in quality. Hundredfold Fluke, 18 lb. 11 oz., of medium size, no disease, not ripe, close and inferior in quality. Red Regent, 18 lb. 1 oz., good in size, no disease, tops green, much grown out, close and inferior in quality. King of Earlies, 17 lb. 4 oz., of medium size, no disease, ripe, close in quality. Climax, 17 lb., good in size, no disease, dead ripe, good in quality. Compton's Surprise, 16 lb. 10 oz., good in size, no disease, not ripe, close, and bad in quality. Snowflake, 16 lb. 9 oz., of fair size, no disease, ripe, excellent in quality. Early Perfection, 16 lb., 7 oz., of fair size, no disease, tops green, skin firm, close in quality. Bryanstone Kidney, 15 lb., of good size, no disease, tops green, unripe, close in quality. Rector of Woodstock, 12 lb. 12 oz., of medium size and fair quality, no disease, dead ripe. Fluke, 12 lb. 10 oz., of fair size and good in quality, no disease, ripe. Alpha, 12 lb., 6 oz., of good size and quality, no disease, dead ripe. Devonshire Reds, 12 lb. 5 oz., of medium size, no disease, unripe, close in quality, and very deep-eyed. Louise of Lorne, 11 lb. 10 oz., of medium size, no disease, unripe, much grown out, inferior in quality. Wyatt's Prolific, 10 lb., of medium size, and good in quality, no disease, dead ripe. Red Emperor, Somerset Reds, Carter's Main Crop, 9 lb. 6 oz., good in size, some diseased, tops green, tubers ripe, second-rate in quality. Early White Don, of fair size, but rather close quality, no disease, dead ripe. Jackson's Kidney, 6 lb. 8 oz., small, no disease, dead ripe, good in quality. Wonderful Red Kidney, 5 lb., very small, a few diseased, dead ripe, yellow, and close in quality.

No stimulating manures of any kind were used, or the haulm would have grown too strong, and probably very few Potatoes would have been produced. It will be seen that Brownell's Beauty heads the list, and a fine handsome Potato of good quality it is, nearly averaging $5\frac{1}{2}$ lb. to each stalk. Early Rose is the next heaviest, being a fraction over 2 lb. 9 oz. to the foot, but in wet seasons it is inferior in quality. Brosee's Prolific is the next heaviest cropper, producing $2\frac{1}{2}$ lb. to the foot, and averaging $3\frac{1}{2}$ lb. to each stalk. Of some of the sorts I had but few, but these were very large, having been sent me by a friend who had exhibited them: I therefore planted them further apart, and although the yield was not so great per foot run, the produce of the individual stalks was very satisfactory—thus Extra Early Vermont averaged 5 lb. 1 oz. to each stalk, and Late Rose 4 lb. 1 oz., while the produce of one stalk of the latter alone weighed $6\frac{1}{2}$ lb. Marquis of Lorne averaged $2\frac{1}{2}$ lb., and William, 2 lb. 9 oz. The above was simply a trial of sorts, the Lapstone and Regent being the standard of quality with which, when cooked, they were compared. My stock sorts for the general supply, after the usual early kinds are over, are Ashleaf and Lapstone, Regents and Victorias, and this year Brownell's Beauty, of which I have bought several sackfuls, some of which will be disposed of to cottagers who are anxious to grow it after seeing it here. Carter's Ashtop Fluke, or, as it is sometimes called Haigh's Seedling Lapstone, for dryness, mealiness, and flavour is the best of all Potatoes. Snowflake even does not equal it for mealiness, although the latter is whiter and handsomer in appearance. The Lapstone well repays extra good culture, and should be grown on well-trenched ground, as it produces great numbers of tubers to each stalk, and they are small if not grown under favourable circumstances. Regents and other strong-growing kinds I grow in the field, 3 ft. apart. I plant them 6 in. or 7 in. deep, and do not earth them up, but I keep the ground well hoed between them. About the 20th of July Turnips are sown for sheep between the Potatoes; a man goes between each row and shakes the seed from an ordinary square powder canister, in which a small hole has been made through which the seed can pass. It is then lightly covered with a rake. The Potatoes were dug the second week in August, care being taken not to injure the Turnips, which were then showing their first rough leaves. The Potato haulm was laid in rows on the ground the tubers previously occupied, and was left there to wither. At the approach of rain the Turnips were manured with 5 cwt. of guano sown broadcast, the field consisting of 2 acres, 10 poles, and hand-hoed as soon as they were large enough. In November this field afforded a week's keep for 320 sheep, which well manured it for this year's crop of Potatoes; it has since been turned up in 3 ft. ridges, exposed to what little frost we have had, and it will be planted as soon as favourable weather sets in.

JOHN GARLAND.

Killerton, Exeter.

SALADS AND SLUGS.

EVERY cultivator knows by bitter experience how slugs destroy the various kinds of salading. Hardly has a green Lettuce or other salad leaf appeared aboveground than these marauders are after it; and during the whole progress of existence, from seed-bag to salad-bowl, they never leave it if they can help it, and if the salad be not washed scrupulously clean, they will even follow it there. But during the winter, the cultivator has mostly a respite from slugs, for the first few crisp frosts, if they arrest growth in the plants, also freeze out or off the slugs; but this winter they have clung to the salads all through and finished many of them, Lettuces in my case being smaller in February than they were last October, and the greater part have disappeared altogether. Fortunately, slugs are so far fastidious in their food that they will eat but little Endive as long as any sweet Lettuces remain; hence Endive still abounds in gardens, and will now be perforce the basis of many a salad for several weeks to come, it being a trifle too bitter for the palates of the slugs. In winters like the present the destruction of slugs is a difficult matter. Hot lime will kill them while it remains hot, but during the last five months it has hardly got near to the salads before it cooled and slacked. The slugs did not seem to mind it in the least, and feasted away on the Lettuces to their hearts' content, even though the soil in which they were grown was as white as a chalk-pit with repeated dustings of hot lime; in fact, during such abnormally wet and mild winters as the present the slugs are far more than a match for the salads, as is proved by the scarcity of the latter in many gardens. It is also far less difficult to preserve good salad plants in the open air during a severe winter than during one similar to that just passed through. Those cultivators have been fortunate who have had plenty of frames, pits, or floors of orchard-houses in which to store their salads, and thereby protect them from the slugs. Those intending to sow Lettuces and other saladings in

the open air should remember that the earth is full of these pests, and should sow the seeds in pots or boxes under glass; meanwhile dressing the land over with hot burnt earth, ashes, lime, charred refuse, &c., to get rid of the superfluous stock of slugs bred by the mild, wet winter, before committing young salad plants to the ground.

D. T. FISK.

SALT AS A MANURE.

UNDER this heading I noticed two paragraphs in THE GARDEN recently, and believing that the statements which they contain may tend to mislead the inexperienced, I beg to offer a few remarks thereon. The first paragraph recorded the fact that an American cultivator had had a medal given him for a certain set of experiments in agricultural chemistry, which went to prove that the best manure for Potatoes was salt and soot. That salt may, under certain circumstances, be helpful to the Potato crop there can be little doubt in most soils and situations; however, salt and soot alone will not continue on the same ground to suit Potatoes or anything else. The only circumstances under which salt and soot alone will give greater crops Potatoes than any manure or combination of manures, is when in the soil all the necessary elements exist in due abundance with a deficiency of salt. Such a condition of things in many parts of America can easily be conceived. Salt is a very soluble substance, and in inland districts far from the sea it is either carried down into the sub-soil by means of rain or conveyed off the land in the crop. Now, as all crops require some salt, it follows that land continually cropped, and the crop annually removed, in time gets exhausted of this necessary element, and although much of that which is removed may be restored in the form of manure, still much is lost by being filtered away in the earth. Again, crops grow in proportion to the presence of all necessary elements, and should one be deficient a loss will be sustained. Different crops, too, require the different elements in different proportions. Thus Wheat contains far more phosphorus than Potatoes, and Potatoes contain far more potash than Wheat, and far more common salt, both in the haulm and in the tubers. Now much of our farmyard manure is decayed Wheat-straw. In time, therefore, our soils get exhausted of salt, while the other elements accumulate. Under such circumstances "no manure or combination of manures" will have anything like the effect of salt. As for soot, it is well known that the stimulating effect of it is due to the ammonia which it contains; and, in addition to ammonia, soot generally contains small quantities of gypsum, nitric acid, &c., and it is to these that "clear soot water" owes its stimulating properties. The other paragraph referred to gave directions for the application of salt to the ground as manure. The first statement was to the effect that salt acted most beneficially on light, sandy soils. There can be no doubt of this, as it is these soils that part with the salt most readily when deluged with rain, as most soils have been during the last winter. Whenever such land lies near the coast, and is subject to rains off the sea, an application of salt would be a superfluity. Dr. Madden states that the rain which annually falls at Penicik, near Edinburgh, contains so much salt as to convey to the land by this means alone as much as 649 lb. to every acre. Your correspondent also recommends its application at the rate of 1 lb. to 1½ lb. per square yard. This is, in round numbers, from 4000 lb. to 6000 lb. per acre. No wonder he recommends putting it on in winter on dug ground "for the rain to wash it in!" The rains would not only need to wash it "in," but "away." Why, such a dose would kill every green thing! Potatoes require as much of this compound as most crops, but there is no more taken from the soil by the heaviest crop of Potatoes than 200 lb. at the utmost, calculating the crop to be 40 tons of tubers and 80 tons of tops. Supposing such quantities as recommended to do no harm, the surplus, especially on a "dry, sandy soil," will be simply washed away by the rain, and lost. A tenth part of the above is surely sufficient, or say 1 lb. to every 10 square yards, and applied in the case of Potatoes after planting, and in the case of Green crops a week or two before, or afterwards as a top-dressing. In inland ground a slight sprinkling of salt in this way benefits all the Cabbage tribe immensely; indeed, all sea-shore plants are benefited by it, and the originals of our race of Cabbages are sea-side plants. They are as much benefited by the application of salt as Seakale or Asparagus; winter Broccoli especially repays with interest such a dressing.

Hope Park.

ALEXANDER HONEYMAN.

Mistletoe on the Oak.—Is not "J. F. S." (see p. 203) mistaken in stating that Mistletoe is found growing on Oaks in Windsor Park? It is generally believed that there are but fifteen known Oaks upon which Mistletoe is found growing in England. They are at the following places, viz., Eastnor, Herefordshire; Badham's Court, near

Chepstow; near Plymouth; Barningford Farm, Dunsfold; Jedstone Delamere, Herefordshire; Knightwick Church, Worcestershire; Hendre, Monmouthshire; Bredwardine, Herefordshire; Forest of Deerfold, Herefordshire; Plas Newydd, Anglesey; Frampton Severn, Gloucestershire; Lee's Court, Faversham; Lindridge, Worcestershire; Hackwood Park, Basingstoke; Cheltenham, Gloucestershire. It would be of interest, too, if authenticated cases of Mistletoe growing on the Oak could be added to the list. In East Kent Mistletoe grows freely on the Lime, Thorn, and Sycamore, sparingly on the Apple, wild Service Tree (*Pyrus torminalis*), Magnolia glauca, and on one Oak. There is growing on a lawn in the centre of the town of Faversham an old Acacia tree with a very large bunch of Mistletoe growing on it: this is the only instance I have known of Mistletoe growing on the Acacia. Can any one tell me if the Loranthus, that is said to grow so freely on the Oaks in Germany, has ever been found growing wild in this country? and also if it is the same variety that is found growing on the Red Gum Tree (*Eucalyptus resinifera*) in Australia?—JAMES PINK, *Lee's Court, Faversham.*

—A few years ago I saw several young plants of Mistletoe growing on the dwarf young Apple trees in the gardens at Bradfield, near Collumpton. The seeds had been inserted in the crevices of the bark and where the spurs started, and had thus struck root. It would be interesting to try the seeds on other trees, as mentioned by your correspondents (see pp. 145 and 203). I have seen Mistletoe growing freely on Thorns at Kwole Park, Sevenoaks, Kent, as well as on Apple trees in that neighbourhood; but it is not found in this district, although there is such a large acreage of land under orchards.—JOHN GARLAND, *Killerton, Exeter.*

—I have found that Mistletoe is more frequently found on Thorns than on any other tree. The very largest pieces of it I ever saw were on a Lime. I once cut a piece from that tree that was 5 ft. in diameter. At Hackwood Park, in Hampshire, it grows on the following trees, viz., Oak, Lime, White Beam, two varieties of Maple, Apple, Thorn, and Mountain Ash. This is the greatest number of trees I have ever noticed Mistletoe on in one place.—H. J. C. GRIMSTON.

HINTS TO PRESS CORRESPONDENTS.

NEVER write with pen or ink. It is altogether too plain, and doesn't hold the minds of the editor and printers closely enough to their work.

If you are compelled to use ink, never use the blotting-pad. If you drop a blot of ink on the paper, smear it off. The Intelligent Compositor loves nothing so dearly as to read through the smear this will make across twenty or thirty words. We have seen him hang over such a piece of copy half an hour, swearing like a pirate all the time.

Don't punctuate. We prefer to punctuate all manuscript sent to us, and don't use capitals. Then we can punctuate and capitalize to suit ourselves, and your article, when you see it in print, will astonish, even if it does not please you.

Don't try to write too plainly. It is a sign of plebeian origin and public school breeding. Poor writing is an indication of genius. It's about the only indication of genius that a great many men possess. Scrawl your article with your eyes shut, and make every word as illegible as you can.

Avoid all palstalking with proper names. We know the full name of every man, woman, and child, and the merest hint at the name is sufficient. For instance, if you write a character something like a drunken figure "8," and then draw a wavy line, and the letter M and another wavy line, we will know at once that you mean Samuel Morrison, even though you may think you mean Lemuel Messenger. It is a great mistake that proper names should be written plainly.

Always write on both sides of the paper, and when you have filled both sides of every page trail a line up and down every margin, and back to the top of the first page, closing your article by writing the signature just above the date. How we do love to get hold of articles written in this style! And how we would like to get hold of the man who sends them! Just for ten minutes. Alone in the woods, with a cannon in our pocket! Revenge is sweet.

Coarse brown wrapping paper is the best for writing your articles on. If you can tear down an old circus poster and write on the pasty side of it with a pin stick, it will do still better.

When your article is complete, crush your paper in your pocket, and carry it two or three days before sending it in. This rubs off the superfluous pencil marks, and makes it lighter to handle.

If you can think of it, lose one page out of the middle of your article. We can easily supply what is missing, and we love to do it. We have nothing else to do!—Burlington Hawk-eye.

Old Mortar for Succulents.—"D." (see p. 103) recommends "sandy loam and a fourth part of dry mortar beaten up into a rough powder" as a compost for Aloe variegata, and doubtless it may succeed in such a compost. I have, however, discontinued lime-rubbish in soil for Cacti or succulents generally, because experience has convinced me that it was not beneficial or in any way necessary. I consider this a question of importance, particularly in the United States, which suits succulents so well, and where they are fast coming into favour. What has Mr. Croucher to say on the subject?—WILLIAM FALCONER.

Pansies in Paris Gardens.—Pansies are by far the most numerous early spring flowers in Paris gardens of all kinds. They are very beautiful just now—the flowers attaining a very unusual size, perhaps owing to the beds of rich light earth in which they are planted, or it may be owing to race. Free-growing varieties of the old races of garden Pansies are worthy of more attention than they receive with us as early spring flowers. They are more beautiful than the hybrid kinds so popular of late.—V.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

SEED SOWING.

MARCH dust was probably never more anxiously looked for by cultivators than this year. Everything has been so saturated with wet that seed sowing had almost become impracticable; many crops will therefore be unusually late this year. True, April may remove most of our difficulties; but should it shower down an excess of rain upon us, the prospects of a fruitful season will be sadly blighted, for the soil is, in most cases, cold and sour as well as wet. Seeds or plants put into the ground, lie long before springing up or making any effort to grow. Every available expedient should be employed to forward crops out of the ground rather than hasten them into it, and also to assist them as much as possible to overcome the excess of moisture when once sown or planted out. Potatoes, Peas, Onions, Cauliflowers, Saladings, Beans, &c., may all be forwarded by being sprouted and pushed on to some extent in houses, frames, pits, cellars, sheds, window gardens, or other places. These and many other plants thrive well if transplanted after they have made some progress. Then, again, all the sowings of Cabbages, Broccoli, Savoys, Brussels Sprouts, Kales, &c., usually made in the open air in the spring, had better be made under cover this season. In this way the plants will be likely to escape the grubs and the slugs, as well as be got up to time. Nothing is so injurious as damp beds for seeds. They are almost as fatal to them as to ourselves. Imperfect development and all kinds of constitutional diseases spring forth from such sources, and it is seldom that healthy plants or good returns result from such beginnings of life. The seeds either rot outright or spring forth too soon, and leave most of their growing or staying powers behind them. Besides, by sowing and planting as many crops as possible in dry quarters for a time, a good deal may be done in making seed beds or drills more dry and comfortable for the seeds by the simple expedient of sprinkling a little dry ash or burnt earth under and over them. This is of immense service to the seeds in such seasons as the present. A considerable heap of dry charred refuse, burnt earth &c., is a possibility in every garden, provided proper forethought is exercised. Everything that will burn should be preserved for this purpose—all small prunings and cuttings, roots of Brassicas, tops of Asparagus, Jerusalem Artichokes, Potatoes, &c. Some of these, such as the roots of Cabbages, Broccoli, &c., should be dried first to enable them to burn to any advantage. Such materials as these, with a faggot or so of fire-wood, carefully lighted and consumed without flame, will form a large heap of charred refuse. The fires should be kept smothered in with weeds and refuse of all sorts—clay, loam, or other earth—the object being, in fact, to char the refuse and make as large a heap of ashes or burnt earth, &c., as possible, during the process of combustion. When the fire goes out—which may be days, or even weeks where the heaps are large—remove the whole of the residuum under cover. It may be sifted and sorted in wet weather, reserving the rougher charred pieces for potting or other purposes, and all the finer soil, ashes, &c., for seed sowing. This material possesses at least two of the most valuable qualities, viz., dryness and cleanliness. It is hardly possible to exaggerate the importance of either or both of these qualities as auxiliaries to seed sowing or rather seed germinating in a season like the present. Draw drills or rake a bed smooth for Onion seeds, for instance; then sprinkle the surface, or scatter along the base of the drills a sprinkling of the dry burnt refuse; sow the seeds and cover lightly with this material, and they will come up with a rapidity, strength, and regularity of plant unknown with crops that are cast into the saturated soil without any assistance. These dry dressings are also capital antidotes to slugs and worms. Where either abound, a little quicklime should be added to the burnt earth, &c. As birds abound this spring, wet the seeds and roll them in red lead before sowing, or slightly sprinkle them with paraffin oil.

D. T. FISH.

NOTES OF THE WEEK.

THE SCARLET WINDFLOWER (*Anemone fulgens*).—There can be no doubt that this is a very variable plant, but as it propagates itself from seeds, this fact need scarcely elicit surprise. During the past week we have received fresh blooms from several quarters. A flower sent us by Mr. G. F. Wilson was exactly $3\frac{1}{2}$ in. in diameter, and consisted of fourteen petals; of these the breadth of the widest did not exceed $\frac{1}{2}$ in. Another flower sent us by the Hon. and Rev. J. T. Boscawen from his garden in Cornwall, measured $4\frac{1}{2}$ in. in diameter, and had only eight segments, each of which was 1 in. in breadth and bluntly rounded, not pointed (as in Mr. Wilson's flower and in our coloured plate published last week), the colour also being a more vivid scarlet. Semi-double blooms of *A. pavonina*, and also flowers having a yellowish ring around the central tuft of blue-black stamens, have likewise been sent by other correspondents, and from these, and other information at hand, it is evident that *A. fulgens* runs into the scarlet forms of the common garden Windflower (*A. coronaria*) on the one hand, and into those of *A. stellata* on the other. Nevertheless, the plant has a distinct habitat from either, and in gorgeous beauty is unsurpassed by any other variety of Windflower.

NEW RACES OF CINERARIAS.—Messrs. Vilmorin & Andriens, of Paris, have of recent years taken considerable pains to differentiate (to use a long word) several races of Cinerarias of much value for our greenhouses. Most important, perhaps, of these are the new dwarf kinds with large and finely-formed flowers. We have lately had an opportunity of seeing these in flower and at their full size, and can testify to their merit and distinctness. The dwarfness is not owing to culture under the same conditions as those under which the old and taller kinds were grown; the height of the plants is 4 in. to 5 in. and 6 in., seldom 6 in. The blue Cineraria, a novelty in its way, is grown in quantity true from seed, and will no doubt henceforward be sought for by those who desire blue flowers in spring. A white race is also abundantly grown, and a fine red one is in course of selection, and its coming true from seed so far secured that not more than one or two plants in a hundred vary from the type desired.—V.

FERNS AND LYCOPODS AMONG ORCHIDS.—Orchids grown in pots are, as a rule, set upon inverted flower-pots on stages covered with gravel, shells, or ashes. Where this is the case, a few Ferns and Lycopods of different kinds planted here and there amongst the pots will be found to set off the Orchids to increased advantage, and also afford abundance of fronds for decorative purposes in a cut state. Among large stove or greenhouse plants the same plan might likewise be adopted.—S.

FLOWERS FOR EASTER.—Some idea of the demand which exists for cut flowers at Easter in Covent Garden may be gleaned from the fact that one grower at Acton (Mr. Reeves) has no fewer than 2000 plants of Arum Lilies and 10,000 pots of Tulips, all being brought into bloom expressly for cutting during the Easter week. Of the Tulips Mr. Reeves informs us he has already orders for 500 bunches of cut flowers, and if these average twelve in a bunch, that alone would exhaust 6000 bulbs.

A MEMORIAL GARDEN.—Seeing that the highly decorated Albert Memorial in Kensington Gardens is suffering from the effects of the weather, Mr. John Wills, in a circular now before us, suggests that it should be covered with a conservatory in five main divisions, the central portion to protect the memorial itself and shelter visitors during inclement weather, and the other four divisions to be planted with the most attractive vegetation of Europe, Asia, Africa, and America, in association with the four groups of symbolic sculpture which now grace the corners of the memorial. If this project be well carried out, we see no reason why it should not be a success.

HARDY PRIMROSES.—Of these, many acres of which are now in bloom in old-fashioned places, we have just seen a beautiful batch of seedling forms from Mr. A. Clapham, of Scarborough, among which are some self-coloured kinds of a rich velvety colour, and also some distinctly-marked fancy varieties. The Hon. and Rev. J. T. Boscawen has also sent us a collection of wild forms collected in a Cornish wood. Among these we remarked a good double, sulphur-tinted variety, and white, lilac, pink, dove-coloured, and yellow forms were also represented, the flowers being large in size; and for ordinary decorative purposes it is difficult to imagine any early-blooming hardy flowers equal to these handsome wild Primroses.

LACHENALIA TRICOLOR IN BASKETS.—Baskets filled with this *Lachenalia* are at this season of the year very pretty in conservatories or greenhouses. Suspended from the roof of one of the houses in Messrs. Veitch's nursery, are a pair of baskets filled with it, each of which is bearing no fewer than 150 or 200 spikes of tube.

shaped, yellow, scarlet-tipped blossoms. These, associated with abundance of green, healthy, pendent leaves, are most pleasing and attractive.—Q.

IMPORTATIONS OF LILY OF THE VALLEY.—A London florist states that he yearly imports from Germany 6000 clumps of Lily of the Valley, and that in addition to these he also uses several thousand single-flowering crowns. The average weight of his importations is something like four tons.—S.

FORSYTHIAS IN IVY.—In the Parc Battes, Chamnot, at present there is a pretty effect afforded by bushes of Forsythia growing on rocky banks covered densely with green Ivy, the Forsythias being quite free and unrestrained in their growth. The beauty of many shrubs is marred by nailing them primly on walls and otherwise mutilating them.—J.

ODONTOGLOSSUM LUTEO-PURPUREUM.—A plant of this *Odontoglossum* in Messrs. Veitch's nursery at Chelsea is now bearing six flower-spikes, from 3 ft. to 4 ft. in length, each being studded with from ten to twelve large flower-buds, which, when fully open, cannot fail to be very effective.—S. W.

MASDEVALLIA VEITCHIANA.—Plants of this Orchid are now flowering freely in the Exotic Nursery, Chelsea, where many of the blooms measure 5 in. in length and 2 in. in width, and possess a brilliancy of colour, to be found in few other flowers. Such plants as this that will thrive under ordinary treatment in any cool airy greenhouse can scarcely be too highly prized or too extensively grown.—C.

THE GOLDEN-LEAVED AUBRIETIA (*Aubrietia purpurea aurea*).—This is a pretty variety having pale yellow leaves and soft purple flowers, like those of the type. Messrs. Backhouse speak in high terms of its decorative qualities. If as hardy and as vigorous in habit of growth as the normal green-leaved form, it will be a useful addition to dwarf rock plants.—M.

DIOSMA CAPITATA.—Hundreds of this old-fashioned hard-wooded greenhouse plant may now be seen in the Exotic Nursery, Chelsea, thickly studded with manve-coloured woolly-looking flowers, which, associated with those of other plants, are by no means ineffective, blooms of this particular colour being comparatively scarce at this season of the year.—S.
